By heating benzoic acid, NaCl, and $K_2S_2O_7$ at 200° (Beketoff, *A.* 109, 256).—6. By the action of $COCl_2$ on benzene in presence of Al_2Cl_6 (Friedel, Crafts, a. Ador, *B.* 10, 1855).—7. From benzoic acid or benzoates and S_2Cl_2 (Carius, *A.* 106, 300).—8. By heating benzoic acid with $ZnCl_2$ and adding benzotrichloride (*D. P. J.* 239, 157). $C_6H_5CCl_3 + C_6H_5.CO_2H = 2C_6H_5.COCl + HCl$.

Properties.—Colourless pungent oil. Decomposed into HCl and benzoic acid slowly by cold, quickly by hot, water. Alcohol reacts vigorously, forming benzoic ether and HCl. Ether and CS_2 dissolve it without decomposition.

Reactions.—1. Aqueous KOH gives KOBz and KCl.—2. Dry BaO at 150° forms Bz_2O (Gal, *A.* 128, 127).—3. Dry NH_3 or *ammonium carbonate* forms benzamide; other bases act similarly.—4. *Sodium* has no action in the cold, but in presence of ether at 100°, 'dibenzoyl' [140°] is slowly formed (Briegel, *Bl.* [2] 5, 278). 5. *Hydride of Copper* forms Cu_2Cl_2 and benzoic aldehyde (Chiozza, *A.* 85, 232).—6. KI forms BzI.—7. $HgCy_2$ forms BzCy.—8. KSCN forms benzonitrile, CO_2, and CS_2 (Limpricht, *A.* 99, 117).—9. Pb(SCN) forms BzSCN.—10. KNCO forms benzonitrile (Schiff, *A.* 101, 93) and cyaphenine (Cloez, *Bl.* 1859, 100).—11. NaOBz gives Bz_2O (Gerhardt).—12. *Sodium formate* forms CO, NaCl, and benzoic acid.—13. Potassium oxalate forms Bz_2O, KCl, CO, and CO_2.—14. By the dry nitrates of Pb, Ag, Hg, or Cu, it is converted into benzoic anhydride, with formation of the chloride of the metal, N_2O_4, and oxygen (Lachowicz, *B.* 18, 2990).—15. Conc. H_2SO_4 forms, apparently, $Bz.SO_4H$, which on heating becomes benzene-sulphonic acid (Oppenheim, *Z.* [2] 7, 21).—16. PCl_5 at 200° gives $C_6H_5.CCl_3$, $C_6H_4Cl.CCl_3$, $C_6H_3Cl_2.CCl_3$ and at a higher temperature CCl_4 and chlorinated benzenes (Schischkoff a. Rösing, *J.* 1858, 279; Limpricht, *A.* 134, 55; Claus a. Hoch, *B.* 19, 1194).—17. KHS forms BzSH.—18. BaO_2 gives Bz_2O_2.—19. *Sodium amalgam* in acid solution forms benzoic aldehyde and benzyl alcohol (Lippmann, *A.* 137, 252).—20. KNH_2 forms benzamide and dibenzamide (Baumert a. Landolt, *A.* 111, 1).—21. *Succinic ether* at 200° gives succinic anhydride, EtOBz, and EtCl (Kraut, *A.* 137, 254).

Combination.—$TiCl_4BzCl$. [65°]. Yellow crystals (Bertrand, *Bl.* [2] 34, 631).

BENZOYL-CHLORO-TOLUIDE *v.* CHLORO-TOLUIDINE.

BENZOYL-CHOLIC ACID *v.* CHOLIC ACID.

BENZOYL-CROTONIC ACID $C_{11}H_{10}O_3$ *i.e.* $C_6H_5.CO.C(CH_3):CH.CO_2H$. [113°]. Long pointed crystals. Prepared by the action of Al_2Cl_6 on a mixture of benzene and citraconic anhydride. By alkalis it is resolved into phenyl ethyl ketone and glyoxylic acid (Pechmann, *B.* 15, 891).

BENZOYL-CUMIDIC ACID *v.* PHENYL-XYLYL-KETONE DI-CARBOXYLIC ACID.

BENZOYL CUMIDINE *v.* CUMIDINE.

BENZOYL-CYANACETIC ETHER *v.* CYANO-BENZOYL-ACETIC ETHER.

BENZOYL CYANIDE $C_6H_5.CO.CN$. [33°]. (208°). Formed by distilling BzCl with $HgCy_2$ or AgCy (Liebig a. Wöhler, *A.* 3, 267; H. Strecker, *A.* 90, 62; Hübner a. Buchka, *B.* 10, 480; Kolbe, *A.* 90, 63; 98, 347). Formed also by mixing isonitroso-acetophenone $C_6H_5.CO.CH:NOH$ with AcCl in the cold, and then distilling the mixture. The isonitroso-acetophenone need not be separately prepared, but amyl nitrite (1 mol.) can be allowed to drop slowly into a warm mixture of acetophenone (1 mol.) and acetyl chloride (3 mols.), and the product distilled; yield: 65–70 p.c. of the theoretical (Claisen a. Manasse, *B.* 20, 2196). Pungent crystalline mass. Decomposed slowly by water, more readily by KOHAq into HOBz and HCN. Fuming HCl forms $C_6H_5.CO.CO.NH_2$ whence phenyl-glyoxylic acid. Zinc and HCl reduce it to benzoic aldehyde. NH_3 gives benzamide and NH_4CN. *Aniline* gives benzanilide. PCl_5 appears to form $C_6H_5.CCl_2.CN$ (224°) (Claisen, *B.* 12, 626). $ZnEt_2$, diluted with ether forms 3 p.c. of 'benzcyanidine' $C_{21}H_{19}NO_2$, [121°], needles (from alcohol); another product (200°–220°), either contains phenyl ethyl ketone or yields that body on oxidation (Frankland a. Louis, *C. J.* 37, 742).

BENZOYL CYANIDINE *v.* BENZOYL CYANIDE.

BENZOYL CYANURATE *v.* CYANURIC ACID.

BENZOYL - CYMENE - SULPHAMIDE *v.* CYMENE SULPHONIC ACID.

BENZOYL-CYMENOL *v.* CYMENOL.

BENZOYL CYMIDIDE *v.* CYMIDINE.

BENZOYL DESOXALIC ACID *v.* DESOXALIC ACID.

BENZOYL-ISODURENE *v.* PHENYL TETRA-METHYL-PHENYL KETONE.

o-**TRI-BENZOYLENE-BENZENE** $C_{27}H_{12}O_3$ *i.e.* $C_6(C_6H_4.CO)_3$. [above 360°]. Formed together with methylene-phthalyl by heating phthalic anhydride with malonic ether and sodium acetate, or by the action of H_2SO_4 on phthalyl-acetic acid (Gabriel a. Michael, *B.* 10, 1557; 11, 1007, 1679; 14, 925). Yellow crystals. Soluble in nitrobenzene, nearly insoluble in other solvents. Potash-fusion converts it into phenenyl-tri-benzoic acid $C_6H_3(C_6H_4CO_2H)_3$ [261°].

DI - BENZOYL - ETHANE *v.* DI-PHENYL-ETHYLENE-DI-KETONE.

BENZOYL - ETHYL - ACETIC ACID *v.* BENZOYL ACETIC ACID.

BENZOYL - ETHYL - ANILINE *v.* ETHYL-ANILINE.

BENZOYL - ETHYL - BENZENE *v.* PHENYL ETHYL-PHENYL KETONE.

BENZOYL-ETHYL-*o*-CARBOXYLIC ACID *v.* PHENYL ETHYL KETONE *o*-CARBOXYLIC ACID.

BENZOYL-FORMIC ACID *v.* PHENYL-GLYOXYLIC ACID.

BENZOYL FLUORIDE $C_6H_5.CO.F$. (162°). From HKF_2 and BzCl (Borodin, *A.* 126, 60). Pungent liquid; attacks glass. Decomposed by water into HF and HOBz.

DI-BENZOYL-FUMARIC ETHER $CO_2Et.CBz:CBz.CO_2Et$. Formed by the action of iodine dissolved in ether upon the di-sodium compound of di-benzoyl-succinate, $CO_2Et.CBzNa.CBzNa.CO_2Et$ (Perkin, *C. J.* 47, 262).

BENZOYL-GALLIC ACID *v.* GALLIC ACID.

BENZOYL-GLYCOCOLL *v.* HIPPURIC ACID.

BENZOYL-GLYCOLLIC ACID *v.* GLYCOLLIC ACID.

α-**BENZOYL-ISO-HEXOIC ACID** *v.* *Iso-butyl*-BENZOYL-ACETIC ACID.

BENZOYL HYDRIDE *v.* Benzoic aldehyde.

DI-BENZOYL-IMIDE *v.* p. 475.

DI-BENZOYL-INDIGO *v.* Indigo.

BENZOYL IODANILINE *v.* Iodo-aniline.

BENZOYL IODIDE $C_6H_5.CO.I$. Easily-fusible crystalline mass obtained by heating BzCl with KI (Liebig a. Wöhler, *A.* 3, 266).

BENZOYL-ISATIN *v.* Isatin.

BENZOYL-ISETHIONIC ACID *v.* Isethionic acid.

BENZOYL-LACTIC ACID *v.* Lactic acid.

BENZOYL-LEUCINE *v.* Leucine.

TRI-BENZOYL-MELAMINE *v.* Melamine.

BENZOYL-TRIMELLITIC ACID. *Benzophenone tricarboxylic acid* $C_{16}H_{10}O_7$ *i.e.* $C_6H_5.CO.C_6H_2(CO_2H)_3$ [5:1:2:4]. From phenyl ψ-cumyl ketone by oxidation with dilute HNO_3 or $KMnO_4$ (Elbs, *J. pr.* [2] 35, 494). **Salts.**—BaHA‴.

BENZOYL-MESIDIDE *v.* Mesidine.

BENZOYL-MESITYLENE *v.* Phenyl tri-methyl-phenyl ketone.

Dibenzoyl-mesitylene *v.* Di-phenyl tri-methyl-phenylene diketone.

Tri-benzoyl-mesitylene $C_{30}H_{24}O_3$ *i.e.* $(C_6H_5.CO)_3C_6Me_3$. *Tri-phenyl tri-methyl-phenenyl tri-ketone.* [216°]. Formed by heating benzoyl mesitylene or di-benzoyl-mesitylene with BzCl and Al_2Cl_6 at 198°. Crystals (from alcohol), v. sl. sol. cold alcohol, v. sol. a mixture of chloroform and acetone. When BzCl acts on mesitylene in presence of Al_2Cl_6 below 118° only benzoyl-mesitylene is formed; at 150° di-benzoyl-mesitylene is the chief product (Louise, *C. R.* 98, 1440; *A. Ch.* [6] 6, 237).

o-**BENZOYL-MESITYLENIC ACID** $C_{16}H_{14}O_3$ *i.e.* $C_6H_5.CO.C_6H_2Me_2COOH$. *Phenyl xylyl ketone carboxylic acid.* [185°]. Prepared in the same way as the *p*- acid (*v. infra*) (Louise, *Bl.* [2] 44, 418). Colourless crystals, insol. cold water, sl. sol. boiling water, sol. $CHCl_3$, acetone, ether, and benzene. Its salts do not crystallise well.—AgA′. CuA'_2.

p-**Benzoyl-mesitylenic acid** $C_{16}H_{14}O_3$. [160°]. Prepared by oxidising phenyl tri-methyl-phenyl ketone (benzoyl-mesitylene) (Louise, *Bl.* [2] 44, 418; *A. Ch.* [6] 6, 218). Nacreous scales, very sol. ether, $CHCl_3$, acetone, &c., sol. boiling water.

Salts.—$A'NH_4$: small brilliant crystals.—A′Ag: white pp. sol. boiling water. A'_2Ba 2aq: long needles. A'_2Ca: long white filaments.—A'_2Mg 6aq: crystals, sol. hot water.—SrA'_2.

BENZOYL-METHANE *v.* Acetophenone.

Di-benzoyl-methane *v.* Di-phenyl methylene diketone.

Tri-benzoyl-methane $(C_6H_5.CO)_3CH$. *Methenyl tri-phenyl tri-ketone* [225°]. Formed by the action of benzoyl-chloride on sodio-di-benzoyl-methane (Baeyer a. Perkin, *B.* 16, 2135; *C. J.* 47, 240). Small needles. Sublimable. V. sl. sol. alcohol, v. sol. dilute alcoholic KOH. Converted by NaOEt and BzCl into a substance [260°-270°].

BENZOYL-METHYLAMINE *v.* Methyl-amine.

BENZOYL-METHYL-ANILINE *v.* Methyl-aniline.

BENZOYL-DIMETHYLANILINE *v.* Di-methyl-amido-benzophenone.

BENZOYL-TRIMETHYLENE *v.* Phenyl tri-methylene ketone.

DI-β-BENZOYL-DI-METHYL-MALONIC ACID $(C_6H_5.CO.CH_2)_2C(CO_2H)_2$. *Di-phenacyl-malonic acid.* [184°]. Formed by saponification of its ether, which is obtained by the action of ω-bromo-aceto-phenone upon sodio-malonic ether. Large colourless prisms. V. sol. alcohol, ether, and acetic acid, sl. sol. water, insol. benzene and ligroïn. Reacts with phenyl-hydrazine. Evolves CO_2 on heating, giving di-benzoyl-isobutyric acid.—*$A''K_2$: white needles or plates, v. sol. water.—*$A''Ag_2$: nearly insol. white pp.

Di-ethyl ether $A''Et_2$: [119°]; large white glistening prisms or long flat needles; v. sol. water, benzene, acetic acid, and CS_2, less in alcohol, insol. ligroïn. Reacts with phenyl-hydrazine but not with hydroxylamine (Kues a. Paal, *B.* 19, 3144).

BENZOYL-METHYL-*p*-NITRANILINE *v. p*-Nitro-phenyl-ω-amido-acetophenone.

BENZOYL-METHYL-PHENYL-NITROSAMINE *v.* Phenyl-amido-acetophenone.

BENZOYL-NAPHTHALIDE *v.* Naphthyl-amine.

BENZOYL-NAPHTHYLAMINE-IMIDE-CHLORIDE *v.* ω-Chloro-benzylidine-naphthyl-amine.

BENZOYL-NAPHTHYL-THIO-UREA *v.* Naphthyl-thio-urea.

BENZOYL-NITRANILIDE *v.* Nitro-aniline.

BENZOYL-NITRITE $BzNO_2$ (?). An oil formed together with *m*-nitro-benzoic aldehyde by the action of 20 vols. of a mixture of HNO_3 (1 vol.) and H_2SO_4 (2 vols.) upon 1 vol. of benzoic aldehyde (Lippmann a. Hawliczek, *B.* 9, 1463). It is decomposed by distillation.

BENZOYL-NITRO-AMIDO-DIPHENYL *v.* Nitro-amido-diphenyl.

BENZOYL-NITRO-AMIDO-PHENOL *v.* Nitro-amido-phenol.

BENZOYL NITRO-ANISIDINE *v.* Nitro-amido-phenol.

BENZOYL NITRO-CUMIDINE *v.* Nitro-cumidine.

BENZOYL-NITRO-NAPHTHALIDE *v.* Nitro-naphthylamine.

BENZOYL-NITRO-DIPHENYLAMIDE *v.* Nitro-diphenylamine.

BENZOYL-NITRO-TOLUENE SULPHAMIDE *v.* Nitro-toluene sulphonic acid.

BENZOYL-NITRO-TOLUIDE *v.* Nitro-toluidine.

BENZOYL PEROXIDE $C_{14}H_{10}O_4$ *i.e.* Bz_2O_2. [104°]. BzCl is mixed with hydrated BaO_2 and the resulting solid cake washed with water and Na_2CO_3, and crystallised from CS_2 (Brodie, *Pr.* 9, 361; 12, 655; Sperlich a. Lippmann, *Sitz. B.* 62, 613). Trimetric crystals, insol. water, v. sol. ether and benzene. Decomposed by heat, giving off CO_2 with slight explosion. Boiling KOHAq forms O and KOBz. Benzoyl peroxide acts as an oxidising agent, splitting up into Bz_2O and O: thus it oxidises *p*-toluidine to toluene-azo-toluene.

BENZOYL-PHENOL $C_6H_5.OBz$ *v.* Phenol; $C_6H_5.CO.C_6H_4OH$ *v.* Oxy-benzophenone.

BENZOYL-PHENOL SULPHONIC ACID *v.* Phenol sulphonic acid.

BENZOYL-PHENYL-AMINE $C_6H_5.CO.C_6H_4NH_2$. Benzanilide (18 g.), BzCl (14g.), and $ZnCl_2$ give the *p*-benzoyl derivative [150°], together with a little of the *o*-benzoyl-

WATTS'

DICTIONARY OF CHEMISTRY

REVISED AND ENTII

BY

PREFACE.

Twenty-five years have passed since the publication of the first edition of *Watts' Dictionary of Chemistry* began, and it is now seven years since the second part of the last supplement was published.

Some time before his death, Mr. Watts had agreed to prepare a new edition of his Dictionary, which should give as complete an account of the present state of the science as might be found compatible with the appearance of the book in four volumes of about 750 pages each. Mr. Watts had prepared *Instructions to Contributors*, and had written sixty-three pages for the new edition, when his death—which all chemists so deeply lamented—stopped the work. It has fallen to us to take up the task dropped from worthier hands, and to endeavour to bring it to a satisfactory conclusion.

Mr. Watts' MS. is printed very much as he left it, subject only to some necessary condensation. In preparing a new edition we have found it necessary to rewrite the whole book. Our instructions were that we should give as complete and satisfactory an account of the present state of chemical science as we could, consistently with the size to which we were required to confine the book. We have been obliged, therefore, to adopt a very condensed style; the descriptions of individual bodies are given in few words, abbreviations are freely used, and formulæ are frequently employed instead of names in order to save space.

The original edition was called 'A Dictionary of Chemistry and the Allied Branches of other Sciences;' the new edition deals with chemistry only. Considerable space was devoted in the original work to processes of chemical technology; the new edition gives no special information with regard to these matters. Technical chemistry will be treated in a companion volume to be published under the editorship of Professor Thorpe. The great importance of the application of physical methods to chemical questions has made it necessary to consider these methods and the results gained by applying them. Hence in our enumeration of the properties of each element and compound we have included those physical constants which are of most importance to the chemist; and we also intend to describe the leading physical methods of investigation employed in chemistry, and to give a short account of the chief results obtained, in an article entitled *Physical Methods used in Chemistry.* This article will be divided into sections, each of which will be written by a specially qualified author.

After much consideration, it was decided to omit details regarding analytical processes. In certain cases, e.g. *Arsenic* methods of detection are given rather fully. But the new edition is not intended for the use of the analyst in the laboratory. A sketch of the principles of analytical chemistry, and some account of the chief classes of analytical methods, are given in the article *Analysis*. We have been especially anxious to arrange the matter in a methodical manner, so as to make the task of finding the chief facts about any specified body as little laborious as possible. Cross-references are freely used.

As mere descriptions of individual bodies in strictly alphabetical order cannot suffice to give a fair notion of the present position of chemistry, we have supplemented these descriptions by short general articles on classes of elements and compounds, e.g. *Alkali Metals, Carbon Group of Elements, Oxides, Hydroxides, Hydrates,* and *Amines.* We have also devoted considerable space to articles on important theories, hypotheses, and principles. Some of these articles may be found to overlap, e.g., *Chemical Change* and *Equilibrium, Chemical*; but the great importance of the subjects treated in such articles is, in our opinion, sufficient warrant for devoting much space to their consideration, and for inviting different authors to treat parts of the same subject from different points of view.

One of the editors is responsible for the inorganic and general, and the other for the organic, chemistry in this work. This division was absolutely necessary if the book was to appear in a reasonable time; and moreover the nature and arrangement of a Dictionary enables various writers to co-operate in its production without material injury to the unity of the work.

We have been fortunate in securing the help of many contributors—English, American, and Foreign—whose work and position enable them to speak with authority on the subjects of which they treat.

We have had the advantage of the advice and assistance of Prof. G. Carey Foster, F.R.S., and Dr. W. J. Russell, F.R.S. To these gentlemen, and to all our contributors and abstractors, we return our sincere thanks.

Each editor contributes an introduction to his special part. It is hoped that the reader will not pass over these introductions, as they give the necessary explanations of the plan on which the book has been written. The table of abbreviations used is also important.

H. Forster Morley.
M. M. Pattison Muir.

March, 1888.

INTRODUCTION

TO THE PORTION OF THE BOOK DEALING WITH INORGANIC CHEMISTRY.

EACH element is described in its alphabetical position. The account of the element is llowed by accounts of its binary compounds and those compounds which may be called ouble binary, in alphabetical order; *e.g. bromides, chlorides, chloriodides, sulphochlorides,* c.; but *cyanides* are placed together in one article. There are also short articles on ROMIDES, CHLORIDES, OXIDES, &c.; and an article is devoted to each class of elements, *e.g.* LKALI METALS, CARBON GROUP OF ELEMENTS, &c. Ammonium is treated as an element o far as the description of the AMMONIUM COMPOUNDS is concerned. Each group of salts, with he exception of those mentioned above, is described under one heading; *e.g.* all *carbonates* re described under the heading CARBONATES, all *nitrates* under the heading NITRATES, and o on. The salts of any specified metal are not as a rule enumerated in the article devoted to he metal; but in a section of this article is given a short account of the salts of the metal onsidered as a class. When some salts belonging to one class are marked off from the thers member of the class, a short article is devoted to a description of these salts as a hole, &c.; thus there is an article on ALUMS, and each alum is described in the article ULPHATES.

The nomenclature adopted is generally that used in the *Journal of the Chemical Society*, but it has not been thought expedient to attempt great strictness in this depart-nent. Structural formulæ are seldom used for inorganic compounds.

The term *molecular weight* is generally used only of those elements and compounds which have been gasified, and the specific gravities of which in the gaseous state have been determined.

The term *valency* is only applied to atoms, and is used to denote the maximum number of atoms of hydrogen, fluorine, chlorine, bromine, or iodine with which one atom of a specified element is known to combine to form a gaseous molecule.

The symbol Aq is employed to denote an indefinite quantity of water; when Aq is added to the symbol of an element or compound it means an aqueous solution of this body.

The following gentlemen have been so good as to prepare abstracts of the papers dealing with inorganic chemistry which have appeared in the various journals since the publication of the last supplement to the first edition of this Dictionary:—Messrs. Cosmo I. Burton, William Burton, G. J. Hill, H. A. Lawrance, Chas. Slater, and Alfred E. Tutton. I am much indebted to these gentlemen, and also to Miss Ida Freund, Lecturer in Chemistry at Newnham College, Cambridge, who prepared a translation of Prof. Ostwald's article on Affinity, and I beg to tender them my best thanks.

M. M. PATTISON MUIR.

INTRODUCTION

TO THE ARTICLES RELATING TO ORGANIC CHEMISTRY.

ORGANIC chemistry probably includes a greater number of observed phenomena than any other science; it is, clearly, not possible to arrange the description of these in such a way that any one, ignorant of the method of arrangement, could readily obtain the information he required. The reader is therefore requested to look through this introduction before referring to any of the organic articles.

The general idea is to devote a separate article to each compound and to arrange these articles in strictly alphabetical order; exceptions are made in the salts of acids and of bases, the ethers, chlorides, amides, anilides, and anhydrides of acids, the acetyl and benzoyl derivatives of compounds containing hydroxyl (OH), amidogen (NH_2), or imidogen (NH), the alkyl derivatives (ethers) of compounds containing hydroxyl, and the oxims and hydrazides of ketones and aldehydes; all these are described in the same article as the parent substance.

The headings of separate articles are in thick **BLACK CAPITALS**, the salts are in spaced type, the alkyl and alkoyl derivatives are in *spaced italics*; derivatives of derivatives are in spaced type. Subsidiary articles are in **black type**. In describing a compound the physical constants (e.g. melting-point, boiling-point, solubility, refractive index) are first given, then follow the modes of formation and preparation of the body, then such properties as cannot be expressed numerically, and finally a list of the chief reactions in which it plays a part. Inasmuch as organic substances are chiefly characterised by their melting or boiling points, it has been thought desirable to give these immediately after the name and formula of each compound, so that they may be most readily found. The melting-points are inclosed in square brackets, the boiling-points in round brackets. The modes by which salts, ethers, acid chlorides, and amides are formed from the parent acid are only given in particular cases or when the method used is not general; a similar remark applies to the acetyl- and benzoyl-derivatives of compounds containing hydroxyl or amidogen, and to the oxims and hydrazides of ketones and aldehydes. Information on the preparation and properties of such derivatives will be found in general articles.

Nomenclature.

Constitutional names are usually employed, except when the constitution of a body is doubtful; cross-references will be found under the trivial names. Many trivial names that have been almost universally adopted are nevertheless retained, e.g. aniline, aspartic acid, cinnamic acid, pyrocatechin, hydroquinone, resorcin.

The names of hydrocarbons usually end in *ene* or *ane*, of phenols in *ol*, of bases in *ine*, and of indifferent bodies in *in*.

In naming several *substituting alkyls*, that with less carbon comes first, and when there is an equal number of carbon atoms the unsaturated alkyl comes before the saturated: e.g. methyl-ethyl-succinic acid; phenyl-naphthyl-amine; allyl-propyl-malonic acid. Radicles containing a closed ring, however, precede fatty radicles, unless there is great danger of ambiguity; in the latter case cross-references will be given.

Ethers, acetyl and *benzoyl derivatives* of hydroxylic compounds are placed under the parent substance. Thus anisole and phenyl acetate are described under 'Phenol,' as its methyl ether and acetyl derivative respectively. So also methoxy-benzaldehyde is described under 'Oxy-benzoic aldehyde' as its methyl derivative.

Tetra-alkylated ammonium compounds are usually described under the tertiary amine from which they are derived. Thus phenyl-tri-methyl-ammonium iodide is described under 'di-methyl-aniline' as its methylo-iodide.

Acetyl and benzoyl derivatives of Amines are described under the amines to which they belong; thus acetanilide is described under 'Aniline' as its acetyl derivative. Derivatives of aniline, methylamine, &c., containing other alkoyls are usually described as the anilide, methylamide, &c., of the acid from which they are derived; thus $C_6H_5.SO_2.NEtH$ is described as the ethylamide of 'Benzene sulphonic acid.'

Sulphonic and carboxylic acids (whenever they are so named) are represented as derivatives of the hydrocarbon, not of the radicle, thus $C_2H_2(CO_2H)_4$ is called ethane tetra-carboxylic acid, not acetylene tetra-carboxylic acid; and $C_2H_4(SO_3H)_2$ is called ethane di-sulphonic acid, not ethylene di-sulphonic acid.

When a compound contains several substituents they are named in the following order: *Chloro-*, *Bromo-*, *Iodo-*, *Cyano-*, *Nitro-*, *Oxy-*, *Amido-*, *Sulpho-*, *Carboxy-*. In choosing the naming group (i.e. the group that is not to be represented as a substituent, but in the termination of the name) the following is the order of preference: CO_2H, SO_3H, CHO, SH, OH and NH_2. Amidogen has precedence over hydroxyl in fatty compounds, but the reverse is the case with aromatic compounds; thus we say oxy-propyl-amine, but amido-phenol.

Examples: chloro-bromo-phenol, not bromo-chloro-phenol; chloro-nitro-oxy-benzoic acid, not nitro-chloro-oxy-benzoic acid, nor nitro-oxy-chloro-benzoic acid, nor oxy-chloro-nitro-benzoic acid, nor oxy-nitro-chloro-benzoic acid, nor chloro-oxy-nitro-benzoic acid; sulpho-benzoic acid, not carboxy-benzene sulphonic acid; amido-phenyl mercaptan, not sulphydro-phenyl-amine, nor sulphydro-aniline.

Prefixes indicating position.

The letters ω, α, β, γ, &c., are employed to denote the position of substituents in an open chain of carbon atoms. If the substituent is attached to the terminal carbon atom it is preceded by ω, while α, β, γ, indicate its attachment to the first, second, or third, atom of carbon reckoned along the chain from the terminal atom. There are at least two ends to an open chain; the end to be reckoned terminal is determined by the nature of the compound: in monobasic acids it is the carboxyl, in alcohols the group CH_2OH, and in general the group represented in the termination of the name. Thus $CH_2Cl.CHI.CHBr.CO_2H$ is called γ-chloro-α-bromo-β-iodo-butyric acid.

When α, β, γ, &c., are used in any other sense than that just explained, they are inclosed between brackets; e.g. (β)-naphthol.

Exo- indicates substitution in an open chain, *Eso-* denotes substitution in a ring; these prefixes are used when the exact position of the substituent is unknown. The prefixes *o-*, *m-*, *p-*, (*ortho*, *meta*, *para*) indicate isomerism of the di- derivatives of benzene (*v.* p. 454); *s-* and *u-* are employed as contractions for *symmetrical* and *unsymmetrical*. Thus *s*-di-phenyl-ethane is $C_6H_5.CH_2.CH_2.C_6H_5$ while *u*-di-phenyl-ethane is $(C_6H_5)_2CH.CH_3$.

In derivatives of quinoline (*B.*) signifies the benzene ring and (*Py.*) the pyridine ring. In anthracene, acridines, and azines (*B.*) signifies the benzene rings, (*A.*) denotes the central ring.

Alphabetical Order.

In determining the alphabetical order, the following prefixes are discarded: *mono-*, *di-*, *tri-*, *tetra-*, *penta-*, *hexa-*, *hepta-*, *octo-*, &c., *per-*, *ortho-*, *meta-*, *para-*, *poly-*, *exo-*, *eso-*, *prim-*, *sec-*, *tert-*, *iso-*, *pseudo-*, *allo-*, *α-*, *β-*, *γ-*, *ω-*, *ν-*, *n-*, *o-*, *m-*, *p-*, *ψ-*, *s-*, *c-*, *u-*, *i-*, (*B.*), (*Py.*), (*A.*), and all numbers. Of course when the entire name is numeral, *e.g.* hexadecane, hexane, &c., this rule does not hold. Thus di-bromo-benzene is in the same article as bromo-benzene; paraldehyde is associated with aldehyde, isobutyric acid with *n*-butyric acid, &c. The prefixes pyro- and proto- do not belong to this class.

The presence or absence of hyphens between parts of a name in no way affects its alphabetical position; thus 'Benzylidene' precedes 'Benzyl iodide.'

Formulæ.

Formulæ, to save space, are written as much as possible in one line. A portion of a formula inclosed in brackets is usually supposed to represent a group of atoms more intimately connected with the groups represented by the preceding symbols, which are not in brackets, than with those following, e.g. $CH_2(CO_2H).CH_2.CO_2H$ is succinic acid. When numbers within square brackets follow a formula they refer to the substituents taken in the order in which they occur in the formula: thus $C_6H_3Br(NO_2)(CO_2H)[1:2:6]$ is used as an abbreviation for $C_6H_3Br(NO_2)(CO_2H)[Br:NO_2:CO_2H = 1:2:6]$. The system here adopted differs, therefore from that sometimes employed, according to which the above symbol would mean $C_6H_3Br(NO_2)(CO_2H)[CO_2H:Br:NO_2 = 1:2:6]$. Constitutional formulæ are looked upon by the majority of chemists as nothing more than a short way of indicating which atoms in a molecule are directly combined, and which are only indirectly combined with one another. The followers of Van 't Hoff and Wislicenus, however, suppose that constitutional formulæ can be constructed in the form of solid figures which give some notion of the actual relative positions of the atoms in a molecule. All agree that it is by the use of constitutional formulæ that the remarkable development of organic chemistry has been made, and that they cannot be abandoned until something better can be found to take their place.

It is not possible to find space for discussing the reasons which have led to the adoption of each constitutional formula; where these reasons are not given, a careful consideration of the methods of formation and the reactions of the compound will probably reveal them.

Special Articles.

In a few articles a number of compounds are grouped together, in violation of the foregoing rules. The longest of these are the articles on 'azo-' compounds. Other such articles are on the ammonia derivatives of 'Benzoic aldehyde,' on 'Benzil,' on the organic derivatives of 'Antimony,' 'Arsenic,' and 'Bismuth,' on 'Camphor' and on 'Cellulose.' The following general articles, amongst others, will also be found in this volume: 'Acids,' 'Alcohols,' 'Aldehydes,' 'Alkaloids,' action of 'Aluminium chloride,' 'Amides,' 'Amido-Acids,' 'Amines,' 'Analysis,' 'Anhydrides,' 'Aromatic Series' (see also 'Benzene'), 'Azo-colouring matters,' 'Diazo- compounds,' and 'Bromo- compounds.'

Contracted Expressions.

Since the date to which Watts had brought the record of chemical discovery, the number of organic compounds known has doubled, nevertheless the space allotted to them in the present dictionary is little more than a quarter of that devoted to organic chemistry in the original dictionary and its supplements. It is evident that there must be extreme compression, and this compels the free use of abbreviated expressions; it is hoped, however, that a reader who has once made himself acquainted with the nature of these abbreviations will find that they are very convenient. In the first place, the symbols of a few common reagents are used in the text with purely qualitative meaning, although when connected in an equation they are used in the ordinary sense. The great saving of space (about 200 pages) has compelled the use of this convention, which would be reprehensible under any other circumstances. The use of the contractions 'v. sl. sol.;' 'sl. sol.,' 'm. sol.,' 'v. sol.,' 'v. e. sol.,' and 'sol.,' for 'very slightly soluble in,' 'slightly soluble in,' 'moderately soluble in,' 'very soluble in,' 'very easily soluble in,' and 'soluble in,' enables solubilities to be given in the case of many hundred compounds where space would otherwise have compelled their omission. Of course these terms are vague; where numerical data have been determined, they are usually given in the dictionary, preceded by the letter S. Particular attention should be paid to the exact meaning of these numbers; they denote the number of grammes of a liquid or solid dissolved by a *hundred grammes* of the solvent, but the number of volumes of a gas dissolved by *one volume* of the solvent. Soluble, used as an adjective, the menstruum not being named, means soluble in water.

Constants.

Numerical constants are not given in the form $a + bt + ct^2$, &c., since such expressions not only take up a great deal of room, but are usually worthless, because slight errors of experiment produce an enormous effect upon the constants b, c, &c.; in such cases one or two actual observations, of a kind likely to be useful in identifying the substance, have usually been selected.

It is unfortunate that there is a want of uniformity among authors in the method of recording physical constants. *Specific gravities* are given by most authors without any mention of the temperature of the water that is taken as standard. Some take water at 0°, some at 4°, and others compare the substance with water at the same temperature as itself. Taking the specific gravity of water at 4° as unity, that at 21° will be ·998; that is to say, for a substance whose specific gravity is about 1 we may make an error of ·002 by assuming that the author used water at 4° as a standard, whereas he really used water at 21°. Under such circumstances it would be preposterous to give four places of decimals, and such indefinite specific gravities have been cut down to three decimal places, and even then the last figure is somewhat doubtful.

Heats of formation are usually calculated on the assumption that the heat of formation of 44 g. of carbonic acid is 96,960, and that of 18 grms. of water is 68,360; Stohmann, Rodatz, and Herzberg, however, use 94,000 and 69,000 respectively, hence their heats of formation are not directly comparable with those of other observers.

Molecular refraction is the value of the expression $M\left(\frac{\mu-1}{d}\right)$, where M is the molecular weight, μ the index of refraction, and d the specific gravity of the liquid at 20 compared with water at 4° (Landolt, *P.* 123, 595 ; Brühl, *A.* 200, 139). Other constants, such as $\left(\frac{\mu^2-1}{\mu^2+2}\right)\frac{M}{d}$, have also been used; these are of course not comparable with those first mentioned (*cf.* Brühl, *A.* 235, 1).

The specific rotation is given by most observers for a tube of liquid 100 mm. long, but many French chemists use a 200 mm. tube as a standard, and some even 50 mm. When the length of tube is stated it is easy to apply the correction, but when, as is often the case, an author does not give the length of tube, his numbers are indefinite.

The rotation measured for the neutral tint is of course not the same as that measured for the sodium line, yet authors occasionally fail to mention the kind of light employed. The angular rotation ought to be divided by the specific gravity of the liquid during the experiment, in order that the effect of equal weights of material may be compared; yet it is to be feared that many authors neglect to perform this division, and also to mention that they have not done it.

Authors frequently fail to state whether their *melting* and *boiling-points* have been corrected for the exposure of part of the stem of the thermometer. This may make a difference of 5°. The immersion of the whole of the mercury in the liquid or vapour is indicated by i.V.

References.

Where the same paper is referred to several times in the course of one article, the full reference is given once, and in other places there will be found the first letter or the first two letters of the author's name, inclosed within brackets; thus, if (Perkin, *C. J.* 45, 890) and (P.) are found in the same article, the (P.) is a contraction for (Perkin, *C. J.* 45, 890).

Short Article Expanded.

In order to make sure that the contractions employed are thoroughly understood, a short specimen article will be expanded by simply exchanging the contractions for their equivalents:—

Bromo-di-oxy-benzoic acid $C_6H_2Br(OH)_2CO_2H$ [x:2:6:1]. [184°, anhydrous]. From c-di-oxy-benzoic acid in ether and Br (Zehenter, *M.* 2, 480). Prisms (containing aq); v. sol. alcohol, v. sl. sol. water. Fe_2Cl_6 gives a violet colour to its aqueous solution.—AgA′aq.—BaA′$_2$ 7½aq.—KA′1½aq.

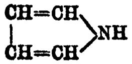
May be expanded thus:—

Bromo-di-oxy-benzoic acid $C_6H_2Br(OH)_2CO_2H$[Br:OH:OH:CO_2H = x:2:6:1] melts at 184° after it has been deprived of its water of crystallisation. It is formed, according to Zehenter (*Monatshefte*, vol. 2, p. 480), by adding bromine to an ethereal solution of *consecutive* di-oxy-benzoic acid. It crystallises in prisms, and the crystals contain one molecule of water of crystallisation to each molecule of the acid. These crystals are very soluble in alcohol, but very slightly soluble in water. Ferric chloride colours its aqueous solution violet. It forms the following salts $C_6H_2Br(OH)_2CO_2Ag,H_2O$; $\{C_6H_2Br(OH)_2CO_2\}_2Ba,7\frac{1}{2}H_2O$ and $C_6H_2Br(OH)_2CO_2K,1\frac{1}{2}H_2O$.

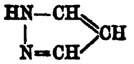
Nomenclature of Rings.

Besides the hydrocarbon rings, represented by benzene, naphthalene, phenanthrene, anthracene, indonaphthene $C_6H_4<\begin{matrix}CH_2\\CH\end{matrix}>CH$, tri-methylene , tetra-methylene , penta-methylene $CH_2<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}>$, &c., there are a great many rings containing other elements. Some of these are collected here for convenience of reference. It will be noticed that glyoxaline and metapyrazole differ only in regard to the position of one atom of hydrogen. The exact structure of rings containing five or six atoms is not known; some alternative formulæ will be found on p. 446.

Nitrogen ring compounds.

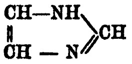


Pyrrole or *Pyrrol.*



Pyrazole.

Metapyrazole.

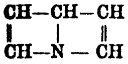


Glyoxaline.

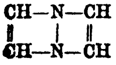
Triazole.

The di-oxy-derivative of the second form of triazol has been named 'Urazole' by Pinner.

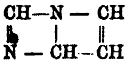
Tetrazole.



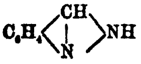
Pyridine.



Pyrazine (type of ketines).



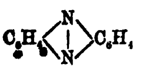
Pyrimidine



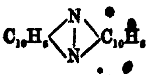
Indazine.

and $C_6H_4<\begin{matrix}CH\\NH\end{matrix}>N$ (pseudo)

$C_6H_4<\begin{matrix}CH\\NH\end{matrix}>CH$ *Indole.*

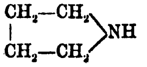


Phenazine.



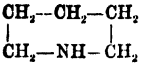
Naphthazine.

$C_6H_4<\begin{matrix}NH\\O\end{matrix}>C_6H_4$ *Phenazoxine*

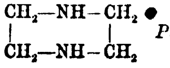


Pyrrolidine.

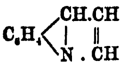
'Pyrroline' has been used by some authors for Pyrrole-dihydride. 'Pyrroline' in the abstracts in the *Journal of the Chemical Society* means Pyrrole.



Piperidine.

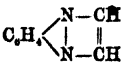


Piperazine.

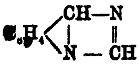


Quinoline.

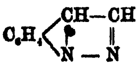
Isoquinoline.



Quinoxaline.

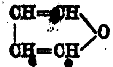


Quinazoline.



Cinnoline.

Oxygen ring compounds.



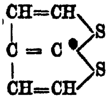
Furfurane.

$C_6H_4\langle{}^{CH}_{O}\rangle CH$ *Coumarone.*

$CH\langle{}^{CH}_{O}\rangle C_6H_2\langle{}^{CH}_{O}\rangle CH$ *Benzodifurfurane.*

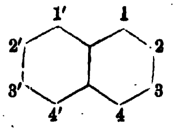
Sulphur ring compounds.

Thiophene.

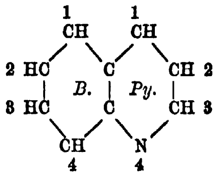


Thiophthene.

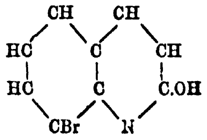
The numbers indicating position in compounds of naphthalene are as follows:—



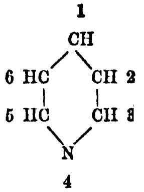
The positions 1, 4, 1′, 4′ are termed (α), while 2, 3, 2′, 3′ are called (β). Quinoline is numbered thus:—



Thus (*B.* 4)-bromo-(*Py*- 3)-oxy-quinoline would be



Pyridine is numbered thus:



One of the assumptions made by the recent doctrine of tautomerism is that a lactam CO.NH can readily change into a lactim C(OH):N, and that the group $CO.CH_2$ can change into C(OH):CH. It is obviously expedient to describe two compounds which are mutually interchangeable, if not identical, in the same article, hence rings containing CO.NH or $CO.CH_2$ are named as if they were hydroxylic compounds of the form C(OH):N and C(OH):CH.

Lactones and Anhydrides.

Lactones and anhydrides are usually described under the substance from which they may be derived by the abstraction of water; thus, butyro-lactone will be described under oxy-butyric acid.

Prefixes discarded.

The prefixes *homo-*, *hydro-*, and *mono-* are not used. The hydro- compounds of unsaturated bodies are, if saturated, named in the usual way; thus hydro-cinnamic acid is phenyl-propionic acid. The hydro- derivatives of ring compounds are described as hydrides of the simpler compounds from which they are derived: e.g. di-hydro phthalic acid as *phthalic acid dihydride.* Compounds beginning with homo- must be re-named; thus homo-salicylic acid is oxy-toluic acid.

Hyphens.

Hyphens are placed between each significant part of a name; absence of the hyphen usually indicates close connection between two groups of atoms; e.g. phenylethylurea is $C_6H_5.C_2H_4.NH.CO.NH_2$ while phenyl-ethyl-urea is $C_6H_5NH.CO.NHC_2H_5$.

Ambiguous names.

A number of names have been used in several senses by different authors; it may therefore be well to mention the names chosen in some of these cases. The terms cyanide and isocyanide are altogether discarded, *carbamine* and *nitrile* being used instead. *Cyanate* is used for ordinary potassium cyanate and the ethers that may be derived therefrom; the corresponding sulphur compounds are described as *sulphocyanides* and *thio-carbimides* (mustard oils). *Cinnamyl* is $C_6H_5.CH{:}CH.CH_2$, the acid radicle $C_6H_5.CH{:}CH.CO$ being *cinnamoyl* and $C_6H_5.CH{:}CH$ is termed *styryl.*

Tolyl is used only for $CH_3.C_6H_4.$ and not for benzyl $C_6H_5.CH_2.$ nor for $CH_3.C_6H_4.CH_2.$

Cresyl is not used as a name. *Xylyl* is only used for $(CH_3)_2C_6H_3.$, not for $CH_3.C_6H_4.CH_2.$ nor for $(CH_3)_2C_6H_3.CH_2.$ *Durene* is used as synonymous with tetra-methyl-benzene.

Discarded names.

As it commonly happens that several names have been given to the same compound, it may be well to give a list of the names that have been chosen in a few cases.

Carbamic ether	is used instead of	*Urethane*
Urea	„ „	*Carbamide*
Thio-carbimide	„ „	*Mustard oil*
Tolylene	„ „	*Toluylene*
Methyl-pyridine	„ „	*Picoline*
Di-methyl-pyridine	„ „	*Lutidine*
Tri-methyl-pyridine	„ „	*Collidine*
Methyl-thiophene	„ „	*Thiotolene*
Di-methyl-thiophene	„ „	*Thioxene*
Oxy-pyridine	„ „	*Pyridone*
Methyl-quinoline	„ „	*Quinaldine*
Diquinoline	„ „	*Diquinolyl*
— hydrazide	„ „	*— izine*
(*B.* 1)-	„ „	*ana-*

Acknowledgments.

I have been fortunate in securing the assistance of Messrs. A. G. Green, V. H. Veley, G. N. Huntly, E. E. Graves, Cecil H. Cribb and Cosmo I. Burton, and of Drs. Samuel Rideal and T. A. Lawson. I am also greatly indebted to Mr. A. G. Green for assistance in revising the proof-sheets. Without the assistance of these gentlemen, it would have been impossible to have done anything like justice to the multitudes of original researches that appear every month, and I have therefore great pleasure in publicly thanking them for the zeal they have shown in endeavouring to render the portion of the Dictionary dealing with Organic Chemistry as far as possible complete.

H. Forster Morley.

II. Terms and Quantities, &c., frequently used.

Aq	Water; *e.g.* NaOHAq means an aqueous solution of caustic soda.
aq	18 parts by weight of water.
A' A'' A'''	Residues of mono-, di-, and tri-basic acids. Thus, in describing the salts of a monobasic acid NaA', CaA'_2, AlA'_3 may be written, HA' standing for the acid. For a dibasic acid we should write Na_2A'', CaA'', $Al_2A''_3$ &c.
B' B'' &c.	Stand for bases of the ammonia type, in describing their salts. Thus the hydrochloride would be B'HCl or B''2HCl, according as the base is monacid or diacid, &c.
conc.	Concentrated.
dil.	Dilute.
g.	gram.
mgm.	milligram.
mm.	millimetre.
mol.	molecule.

oil.	liquid, nearly, or quite, insoluble in water.
pp.	precipitate.
to ppt.	to precipitate.
ppg.	precipitating.
ppd.	precipitated.
sol.	soluble in.
insol.	insoluble in.
v. e. sol.	very easily
v. sol.	very
m. sol.	moderately } soluble in.
sl. sol.	slightly
v. sl. sol.	very slightly
v.	see.
cf.	compare.
c.	about.
[°]	a melting-point.
(°)	a boiling-point.
H.	Hardness (of minerals).
At. w.	Atomic weight.
Mol. w. or M. w.	Molecular weight.
D.	Density.
cor.	corrected.
uncor.	uncorrected.
i.V.	in vapour.
V.D.	vapour-density, *i.e.* density of a gas compared with hydrogen or air.
S.G.	Specific gravity compared with water.
S.G. $\frac{10}{0}$	,, ,, at 10° compared with water at 0°.
S.G. $\frac{15}{4}$	,, ,, ,, 15° ,, ,, ,, ,, 4°.
S.G. ^{12}	,, ,, ,, 12°; compared with water of which the temperature is not given.
S.H.	Specific heat.
S.H.v.	,, ,, of a gas at constant volume.
S.H.p.	,, ,, ,, ,, ,, pressure.
H.C.	Quantity of heat, in gram-units, produced during the complete combustion of the mass of a solid or liquid body represented by its formula, taken in grams.
H.C.v.	Heat of combustion in gram-units of a gram-molecule of an element or compound, when gaseous, under constant volume.
H.C.p.	The same, under constant pressure.
H.F.	Quantity of heat, in gram-units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in grams, from the masses of its constituent elements expressed by their formulæ, taken in grams.
H.F.v.	Heat of formation of a gram-molecule of a gaseous compound from the gram-molecules of its elements under constant volume.
H.F.p.	The same, under constant pressure.
H.V.	Heat of vaporisation of a liquid, *i.e.* gram-units of heat required to change a gram-molecule of the liquid compound at B.P. into gas at same temperature and pressure.
T.C.	Thermal conductivity (unit to be stated).
S.V.	Specific volume; or the molecular weight of a gaseous compound divided by the S.G. of the liquid compound at its boiling-point compared with water at 4°.
S.V.S.	Specific volume of a solid; or the mass of the solid expressed by its formula, taken in grams, divided by its S.G.
E.C.	Electrical conductivity (the unit is stated in each case).
C.E. (10° to 20°)	Coefficient of expansion (between 10° and 20°).
S.	Solubility in water { of a gas = volume dissolved by 1 volume of water. of a liquid or solid = number of grms. dissolved by 100 grms. of water. In both cases the temperature is stated.
S. (alcohol)	,, ,, alcohol
$_{\beta}$	Index of refraction for hydrogen line β.
$_{D}$, &c.	,, ,, ,, sodium ,, D, &c.
$_{D}\ \frac{15}{0}$	Molecular refraction for sodium light, *i.e.* index of refraction for line D minus one, multiplied by molecular weight, and divided by S.G. at 15° compared with water at 0°.
$_{D}$	The same; S.G. being determined at 15°-20° and referred to water at 4°.
$_{\infty}$	The same for line of infinite wave-length, index being determined by Cauchy's formula (Brühl's R_A).

ABBREVIATIONS.

$[\alpha]_D$ . .	Specific rotation for sodium light.	
$[\alpha]_j$ . .	„ „ „ neutral tint. $[\alpha]=\frac{100}{p}\times\frac{a}{d}$. a = observed rotation for 100 mm. of liquid. d = S.G. of liquid. p = no. of grammes of active substance in 100 grammes of liquid.	
M. M	Molecular magnetic rotatory power $=\frac{m\times a}{d\times a'\times m'}$, where m = molecular weight of the body of S.G. = d, a = angle of rotation under magnetic influence, a' = angle of rotation of water under same influence, and m' = molecular weight of water (18).	
Ac . .	Acetyl C_2H_3O.	
Bz . .	Benzoyl C_7H_5O.	
Cy . .	Cyanogen CN.	
Et . .	Ethyl C_2H_5.	in formulæ.
Me . .	Methyl CH_3.	
Ph . .	Phenyl C_6H_5.	
Pr . .	Normal Propyl $CH_2.CH_2.CH_3$.	
Pr . .	Isopropyl $CH(CH_3)_2$.	
R, R' &c.	Alcohol radicles or alkyls.	
prim . .	primary.	
sec . .	secondary.	
tert . .	tertiary.	
n . . .	normal.	
m, *o*, *p* .	meta—ortho—para.	
c . . .	consecutive.	
i . . .	irregular.	
s . . .	symmetrical.	
u . . .	unsymmetrical.	
ψ . . .	pseudo.	
ν . . .	attached to nitrogen.	
α . . β . . γ . .	Employed to denote that the substituent is attached to a carbon atom which is next, next but one, or next but two, respectively, to the terminal carbon atom. The end to be reckoned from is determined by the nature of the compound. Thus $CH_3.CHBr.CO_2H$ is α-bromopropionic acid.	
ω . . .	denotes that the element or radicle which follows it is attached to a terminal carbon atom.	
α,β,γ,&c.	indicate position in an open chain, only.	
1,2,3,&c.	indicate position in a ring only.	
(α), (β), &c.	Used when α, β, &c. are employed in a sense different from the above, *e.g.* (α)-di-bromo-camphor.	
	Baeyer's Nomenclature:	
(*B.*) . .	benzene ring.	
(*Py.*) . .	pyridine ring.	
	Thus (*B.* 1:3) dichloroquinoline, means a meta-dichloroquinoline in which the chlorine atoms are both in the benzene ring. While (*Py.* 1:3) dichloroquinoline, means a similar body, only the chlorine atoms are in the pyridine ring. The numbers are counted from two carbon atoms which are in different rings, but both united to the same carbon atom.	
(*A.*) . .	denotes the central ring in the molecule of anthracene, acridines, and azines.	
eso- . .	means that the element or radicle it precedes is in a closed ring.	
exo- . .	„ „ „ „ „ not in a benzene ring.	
allo- . .	denotes isomerism that is not indicated by ordinary formulæ; thus maleic acid may be called *allo*-fumaric acid.	
thio- . .	denotes displacement of oxygen by sulphur.	
sulpho- .	„ the group SO_3H, except in the word sulphocyanide.	
sulphydro-	„ the group SH.	
-	Tribromonitrobenzene sulphonic acid [1:2:3:4:5] means that the three bromines occupy positions 1, 2, and 3; the nitro- group the position 4, and the sulpho- group the position 5.	

* *Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulæ without this mark are those of analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated otherwise.

Wave-lengths are given in 10^{-7} mm.

Formulæ, when used instead of names of substances, have a qualitative meaning only.

Thomsen's notation is used in thermochemical data.

DICTIONARY OF CHEMISTRY

ABIES.—The needles of *A. pectinata* contain a sugar called *Abietite*, $C_6H_8O_3$, very much like mannite, but differing therefrom in composition and in solubility. The same plant contains a tannin identical with the soluble tannin of the horse-chestnut, $C_{18}H_{12}O_6$, and convertible by hydrochloric acid into an anhydride $C_{52}H_{46}O_{23}$, insoluble in cold water, but soluble in boiling potash-lye, slightly in water and alcohol (Rochleder, *J. pr.* 105, 63, 123).—The fruits of *Abies Reginæ Amaliæ*, indigenous in Arcadia, yield, by distillation with water, about 18 p.c. of a colourless volatile oil $C_{10}H_{16}$, smelling like lemons, S.G. ·868 (156–159°); slightly lævorotatory. Resinifies quickly in the air, exerting an ozonising influence stronger than that of turpentine-oil. Dissolves iodine, and absorbs hydrogen chloride, forming a liquid compound $C_{10}H_{16}.HCl$ (Buchner a. Thiel, *J. pr.* 92, 109). H. W.

ABIETENE C_7H_{16}.—The heptane of *Pinus sabiniana* (*v.* HEPTANES).

ABIETIC ACID $C_{44}H_{64}O_5$ [139°] or [165°].—Caillot, *J. Ph.* 16, 436; Maly, *A.* 129, 94; Emmerling, *B.* 12, 1441; Kelbe, *B.* 13, 888.—*Occurrence.* The clear liquid turpentine of various species of pine contains **abietic anhydride** $C_{44}H_{62}O_4$, which, on exposure to the air, absorbs moisture and is converted into abietic acid, the liquid then coagulating to an opaque granular pulp. The anhydride is the chief constituent of common resin or colophony.

Preparation.—1. Coarsely pounded colophony is digested for two days with weak spirit; the liquid is decanted from the white crystalline pulp, and squeezed in a press; the press-cake dissolved in hot strong alcohol, and the solution left to itself at ordinary temperatures; a white crystalline crust is thus obtained; the mother-liquor, when cooled by ice, usually solidifies to a loose mass of white laminæ, which constitutes the greater part of the product. The crystalline crust consists of sylvic acid $C_{20}H_{30}O_2$, the laminæ of abietic acid (M.).—2. Colophony is digested for two days with spirit of 70 p.c., and the undissolved portion, after washing with weak spirit, is dissolved in the smallest possible quantity of glacial acetic acid. From this solution the acid separates in crusts, and on adding a little water to its solution in hot alcohol and stirring, it is obtained in crystalline scales (E.).—3. Soda-lye which has been used for purifying crude resin-oil is mixed with common salt, and the soap which separates is dried at 70°–80°, and purified by exhaustion with ether. The residue dissolves in alcohol, and the solution, on evaporation, deposits needle-shaped crystals of sodium abietate, the aqueous solution of which yields, on addition of hydrochloric acid, a white pp. of abietic acid, which melts to a resinous mass if the mixture is boiled (K.).

Properties.—Separates from hot alcoholic solution in irregular transparent pointed triclinic crystals melting at 165° (M., K.); 139° (E.); 135° (Flückiger). Sol. alcohol, ether, benzene, glacial HOAc, $CHCl_3$ and CS_2.

Reactions.—1. Abietic acid distilled with *zinc chloride* yields a heavy oil (70°–250°) containing heptylene (E.).—2. Strong *hydrochloric* and *hydriodic acids* at 145° abstract the elements of water from it, leaving the anhydride (E.); but when treated in alcoholic solution with gaseous HCl, it yields sylvic and sylvinolic acids:

$$C_{44}H_{64}O_5 + H_2O = C_{20}H_{30}O_2 + C_{24}H_{36}O_4 \text{ (?)}$$

Sylvic acid is also formed when a hot alcoholic solution of abietic acid is mixed with sulphuric acid (M.).—3. Triturated with PCl_5 it yields on distillation a volatile oil $C_{44}H_{60}$, called by Maly *abietone*, together with HCl and $POCl_3$.—4. By oxidation with $KMnO_4$, abietic acid yields carbonic, acetic and formic acids.—5. Boiled with *chromic mixture*, it yields large quantities of acetic and formic acids, and, after removal of these by distillation, ether extracts from the liquid a small quantity of **trimellitic acid** $C_6H_3(CO_2H)_3$ (E.).—6. The anhydride (colophony), oxidised with *nitric acid*, yields isophthalic acid, together with trimellitic acid (Schreder, *B.* 6, 413).—7. Abietic acid fused with *potash* yields propionic, but no protocatechuic, acid (M.).—8. *Sodium-amalgam* added to a warm alcoholic solution of abietic acid converts it into **hydrabietic acid** $C_{44}H_{68}O_5$, a dibasic acid, which forms white unctuous laminæ melting at 160° (M.).—9. Abietic acid with *acetic chloride* or *anhydride* at 160° yields an oily acetyl-compound (E.).—10. *Bromine* added to a solution of abietic acid in CS_2 forms a bromo-derivative, probably $C_{44}H_{62}Br_2O_5$, which separates from alcohol as a red powder melting at 134° (E.).—11. Distilled with *zinc dust* it yields toluene, *m*-ethyltoluene, naphthalene, methyl-naphthalene, and methyl-anthracene (Ciamician, *G.* [illegible], 305, *B.* 11, 269).

Salts.—Abietic acid is dibasic, mostly forming normal, rarely acid, salts. The alkaline salts are difficultly crystallisable. The normal abietates of the other metals $C_{44}H_{62}M''O_5$ are sparingly soluble in water, and are obtained by precipitation. Na_2A'', needles (from alcohol).—MgA'', flocculent, v. sol. alcohol.—MgH_2A_2''.—CaA''.—BaA''.—ZnA'', sl. sol. alcohol.—CuA'', v. sol. CS_2 or ether; pale green.

Ethyl Abietate Et_2A'', obtained by decomposing silver abietate with ethyl iodide diluted with ether, forms a yellowish mass, having an etheric odour; insoluble in water, slightly soluble in alcohol, easily in ether and CS_2.

Abietin $C_{53}H_{76}O_8$ *i.e.* $C_{44}H_{61}(CHMe:CH)_2O_8$ is deposited from a mixture of glycerin and a concentrated alcoholic solution of abietic acid, after exposure to a low temperature for several days, in small white crystals melting at 125°, soluble in ether and alcohol (M.). H. W.

ABIETIC ANHYDRIDE $C_{44}H_{62}O_4$ is not formed by direct dehydration of the acid, but exists, as already observed, in the clear fresh turpentine of certain conifers, and forms the essential part of colophony. H. W.

ABIETIN. *V. supra.*

ABIETITE $C_4H_8O_3$.—*Abietol.* The sugar of *Abies pectinata.*

ABROTINE $C_{21}H_{22}N_2O$.—An alkaloid from *Artemisia abrotanum* (P. Giacosa, *J.* 1883, 1356). White crystalline powder or white needles. Sl. sol. hot water. Its solutions fluoresce blue. **Salts**: $B''H_2PtCl_6$.—$B_2''H_2SO_4$6aq. Needles.

ABSINTHIN or *Absynthiin* $C_{40}H_{56}O_9$ [120°–125°].—(Mein, *A.* 8, 61; Luck, *A.* 78, 87; Kromayer, *Ar. Ph.* [2] 108, 129).—The bitter principle of wormwood (*Artemisia absynthium*). Prepared by exhausting the dry herb with cold water; absorbing the bitter principle from the concentrated extract with boneblack; extracting with alcohol; purifying by treatment with basic lead acetate, precipitating the lead with H_2S, and evaporating the filtrate.

Properties.—Yellow powder, composed of minute crystals. V. sl. sol. cold water, sl. sol. hot water, v. sol. alcohol or ether. Very bitter. Neutral to litmus. Smells like wormwood.

Reactions.—1. Conc. H_2SO_4 forms a brown solution, turning greenish-blue. A little water turns the colour to a splendid blue, destroyed by more water.—2. Boiling dilute H_2SO_4 acquires a yellowish-green fluorescence, and deposits a brown resin.—3. Does not reduce Fehling's solution.—4. Gives a mirror with warm ammoniacal $AgNO_3$.—5. An alcoholic solution gives a sticky pp. with tannin.—6. Gives no pps. with metallic salts. H. W.

ABSINTHOL.—$C_{10}H_{16}O$ (195°) or (204°).—(Beilstein a. Kupffer, *B.* 6, 1183, *A.* 170, 290; Wright, *C. J.* 27, 1 and 319).—Isomeric with common camphor. Forms the essential principle of wormwood-oil, in which it is associated with a terpene (b.p. below 160°) and a deep-blue oil (270°–300°) identical with the blue chamomile oil examined by Kachler (*B.* 4, 36). Absinthol boils at 195° (B. and K.), at 200°–205° (W.), 217° (Gladstone). Differs essentially from camphor in chemical reactions, not being converted into camphoric acid by oxidation with nitric acid, nor into campho-carboxylic acid, $C_{11}H_{16}O_3 = C_{10}H_{14}(OH).CO_2H$, by sodium and CO_2, and yielding with melting potash a large quantity of resin but no acid. Heated with P_2S_5 it yields cymene $C_{10}H_{14}$, and cymyl hydrosulphide $C_{10}H_{13}SH$, boiling at 230°–240° (W.). Cymene is also formed, though in smaller quantity, by treating absinthol with zinc chloride (W.). H. W.

ABSORPTION OF GASES BY LIQUIDS AND SOLIDS *v.* GASES.

ABSORPTION-SPECTRA *v.* PHYSICAL METHODS: sect. OPTICAL.

ACACIN or *Acacia gum v.* ARABIN.

ACAJOU.—The pericarp of the nuts of the Acajou or Cashew-nut tree, *Anacardium occidentale*, growing in the West Indies and South America, contains a large quantity of a red-brown resinous vesicating substance, which may be extracted by ether, the solution when evaporated leaving a network of small crystals of anacardic acid soaked in an oily liquid called *cardol*, to which the resin owes its acrid properties (Städeler, *A.* 63, 137). A catechin $C_{42}H_{34}O_{16}$ [165°] may be got from acajou-wood (Gautier, *Bl.* 30, 568). H. W.

ACAROID RESIN.—Resin of *Xanthorrhea hastilis*, a liliaceous tree of Australia: also called resin of Botany Bay. Yellow, fragrant, soluble in alcohol, ether and caustic potash. The potash-solution treated with HCl deposits benzoic and cinnamic acids. Nitric acid readily oxidises it to picric acid. Yields on distillation phenol and small quantities of benzene and styrene (Stenhouse, *A.* 57, 84). By potash-fusion it gives *p*-oxy-benzoic acid, resorcin, and pyrocatechin (Hlasiwetz a. Barth, *A.* 139, 78). H. W.

ACECHLORIDE OF PLATINUM *v.* ACETONE.

ACECONITIC ACID $C_6H_6O_6$.—The ethyl ether is formed, together with the (probably isomeric) citracetic ether, by the action of sodium on ethyl bromo-acetate:

$$3EtC_2H_2BrO_2 + 3Na = Et_3C_6H_3O_6 + 3NaBr + H_3$$

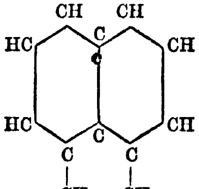
(Baeyer, *A.* 135, 306). The product is distilled *in vacuo*, and the ethers saponified by baryta. Baric aceconitate crystallises, leaving the gummy baric citracetate in solution.

Properties.—Nodular groups of needles. V. sol. ether. Gives no crystalline sublimate.

Salts.—Barium salt forms small, sparingly soluble crystals. A solution of the calcium salt becomes turbid when heated.—Ag_3A'''aq. *Ethyl ether.*—Et_3A'''. Lighter than water. H. W.

ACEDIAMINE $C_2H_6N_2$ *i.e.* $NH_2.CMe:NH$ *v.* ACET-AMIDINE.

ACENAPHTHENE $C_{12}H_{10}$ *i.e.* $C_{10}H_6:C_2H_4$,



M.w. 154. [95°] (Behr a. Dorp, *A*, 172, 265), [103°] (Schiff), (278° i. V.). V.D. 5·35 (for 5·33). S.V.S. 149·16 (Schiff, *A.* 223, 263).

Occurrence.—In coal-tar oil (Berthelot, *Bl.* [2] 8, 226).

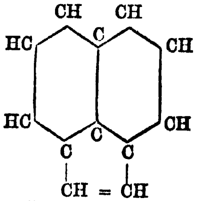
Formation.—1. By passing a mixture of ethylene and benzene or naphthalene through a red-hot tube (Berthelot).—2. By passing (*α*)-ethyl-naphthalene through a red-hot tube.—3. By treating (*α*)-ethyl-naphthalene with Br at 183° and decomposing the product, $C_{10}H_7.C_2H_4Br$, with alcoholic KOH at 100° (Berthelot a. Bardy, *C. R.* 74, 1463).

Preparation.—Heavy coal-tar oil (260°–290°) is carefully fractioned, and the fraction 260°–270° cooled strongly till it solidifies. Recrystallised from alcohol (Terrisse, *A.* 227, 184).

Properties.—Long needles (from alcohol). V. sol. hot alcohol, v. sl. sol. cold alcohol.

Reactions.—1. A mixture of alcoholic solutions of acenaphthene and *picric acid* deposits orange-yellow needles of the *picrate*, $C_{12}H_{10}.C_6H_2(NO_2)_3OH$ [162°].—2. Conc. H_2SO_4 forms a sulphonate whose salts are very soluble. A little HNO_3 turns the solution in H_2SO_4 green. 3. Cold HNO_3 forms *di-nitro-acenaphthene*. Yellow needles (from benzoline); insol. in alcohol.—4. CrO_3 and H_2SO_4 give naphthalic acid, $C_{10}H_6(CO_2H)_2$ (B. a. D.).—5. *Bromine* added to an ethereal solution forms *bromo-acenaphthene*, $C_{10}H_5BrC_2H_4$ [53°]; tables (from alcohol); oxidises to bromo-naphthalic acid (Blumenthal, *B.* 7, 1095).—6. A further quantity of *bromine* added to a solution in CS_2 forms $C_{12}H_8Br_6$; white needles (from alcohol).—7. *Iodine* at 100° polymerises it.—8. Conc. HI at 100° forms a hydrocarbon (? $C_{12}H_{12}$) (c. 270°).—9. Conc. HI (20 pts.) at 280° produces naphthalene di-hydride and ethane.—11. *Potassium* gives off hydrogen, forming $C_{12}H_9K$ (Berthelot).

ACENAPHTHYLENE $C_{12}H_8$ *i.e.* $C_{10}H_6{:}C_2H_2$; probably



[93°] (265°–275°).

Preparation.—Acenaphthene (6g.) is put into a combustion tube, and the rest of the tube filled with litharge. The acenaphthene is heated strongly, and the vapours pass over the litharge, which must not be red hot (Blumenthal, *B.* 7, 1092; Behr a. Dorp, *B.* 6, 753).

Properties.—Large golden plates (from alcohol). Is partly decomposed by boiling. V. e. sol. alcohol, ether or benzene.

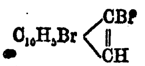
Reactions.—1. *Sodium amalgam* reduces it, in alcoholic solution, to acenaphthene.—2. *Chromic mixture* oxidises it to naphthalic acid.—3. Combines, in ethereal solution, with *bromine*, forming

$$C_{10}H_6\left\langle\begin{matrix}CHBr\\ |\\ CHBr\end{matrix}\right.$$

[121°–123°]. This forms white needles (from benzene mixed with alcohol). Chromic mixture oxidises it to naphthalic acid. Alcoholic KOH converts it into *bromo-acenaphthylene*,

$$C_{10}H_6\left\langle\begin{matrix}CBr\\ \|\\ CH\end{matrix}\right.$$

This is a liquid, but its picrate forms yellow needles. Bromo-acenaphthylene is converted by bromine into orange-red plates of di-bromo-acenaphthylene,



$$C_{10}H_5Br\left\langle\begin{matrix}CBr\\ \|\\ CH\end{matrix}\right.$$

Picrate.—$C_{12}H_8C_6H_2(NO_2)_3OH$ [202°]. Yellow needles. V. sl. sol. cold alcohol.

ACETACETIC ACID *v.* Aceto-acetic Acid.

ACETAL $C_6H_{14}O_2$ *i.e.* $CH_3.CH(OEt)_2$.—*Di-ethyl-acetal, di-ethyl aldehydate* (*v.* Aldehyde). M.w. 118. (104°) (Stas); (103·2°) at 752 mm. (R. Schiff, *A.* 220, 104); (21°) at 22 mm., (50·5 at 121 mm., (102·2°) at 760 mm. (Kahlbaum S.G. $\frac{20}{4}$ ·8314 (Brühl); $\frac{15}{15}$ ·8319, $\frac{25}{25}$ ·8233 (Perkin $\frac{103·2}{4}$ ·7364 (Sc.). V.D. 4·141. *Critical temperatu* 254·4° (Pawlewski, *B.* 16, 2633). S. 4·6 at 25 S.V. 159·88 (Sc.). μ_β 1·386. R_∞ 52·52 (B. M.M. 6·968 at 16·1° (P.).

Occurrence.—In crude spirit, after filterin through charcoal (Geuther, *A.* 126, 63).

Formation.—1. By the imperfect oxidatio of alcohol (Doebereiner; Liebig, *A.* 5, 25; 1 156; Stas, *A. Ch.* [3] 19, 146; Wurtz, *A. C* [3] 48, 370; *A.* 108, 84). Hence its occurrenc in raw spirit and in old wines.—2. By action chlorine on alcohol:

$$3C_2H_6O + Cl_2 = C_6H_{14}O_2 + 2HCl + H_2O.$$

3. One of the products of action of alcohol o ethyl di-bromo-acetate (Kessel, *B.* 11, 1917 4. By passing non-inflammable PH_3 into a mixture of equal volumes of aldehyde and alcoho at -21° (R. Engel a. De Girard, *C. R.* 91, 692 *C. J.* 38, 458).

Preparation.—I. From Alcohol.—1. By imperfect oxidation under the influence of platinum-black. Fragments of pumice are moistene with nearly absolute alcohol in a wide-mouthe flask, the upper part of which is filled wit shallow glass capsules containing platinum black, and the flask, covered with a glass plate is left in a room at 20° till nearly all the alcoho is converted into acetic acid. Alcohol of 60 p.c is then poured in, and the flask, again covere with the glass plate, is exposed to the same temperature for a fortnight or three weeks, by which time the liquid above the pumice will have become viscid. This liquid is then poured off, more alcohol is added, and this course of proceeding is repeated till a few litres of very acid liquid have been obtained. This product is saturated with potassium carbonate, dried with calcium chloride, and about a fourth of it is distilled off; the distillate is treated with calcium chloride; the lower layer of liquid—consisting of aldehyde, ethyl acetate, and alcohol—is again mixed with calcium chloride, and distilled till the distillate no longer reduces silver nitrate; and the residue is treated with potash-lye, washed, dried with calcium chloride and rectified (Stas).—2. By distilling alcohol (2 pts.) with manganese dioxide (3 pts.), sulphuric acid (3 pts.), and water (2 pts.), and rectifying the product, which consists of acetal mixed with aldehyde, ethyl acetate, &c., as above.—3. By passing chlorine through alcohol of 80 p.c. cooled to between 10° and 15° till a portion becomes turbid on addition of water, indicating the formation of substitution-products. One fourth of the acid liquid is then distilled off; the distillate is neutralised with chalk; a fourth part again distilled off; and the distillate, consisting of alcohol, ethyl acetate, aldehyde, and acetal, is treated as above to separate the acetal (Stas). According to Lieben (*A. Ch.* [3] 52, 313), the chief products of the action of chlorine on 80 p.c. alcohol are mono- and di-chloracetal.

II. From Aldehyde.—1. By passing gaseous hydrogen chloride into a mixture of 1 vol. aldehyde and 2 vol. absolute alcohol, cooled by a freezing mixture, whereby the compound C_4H_9ClO is obtained, as an ethereal liquid floating on the aqueous hydrochloric acid, and treating this compound with sodium ethylate:

$$C_2H_4O + C_2H_6O + HCl = H_2O + C_4H_9ClO;$$
$$\text{and } C_4H_9ClO + C_2H_5ONa = NaCl + C_6H_{14}O_2$$

(Wurtz a. Frapolli, *C. R.* 47, 418; *A.* 108, 223). 2. By treating aldehyde with PBr_5, whereby it is converted into ethylidene bromide, and acting on this compound with sodium ethylate:

$$CHMeBr_2 + 2NaOEt = 2NaBr + CHMe(OEt)_2$$

(W. a. P.).

Properties.—Colourless liquid, less mobile than ether, having a peculiar agreeable odour and refreshing taste, with an after-taste like that of hazel-nuts. Separated from aqueous solution by calcium chloride and other soluble salts. Miscible with ether or alcohol.

Reactions.—1. Not altered by mere exposure to *air*, but quickly oxidised in contact with *platinum-black* to aldehyde and acetic acid. Oxidised also by *nitric* and by *chromic acid.*—2. Not decomposed by caustic *alkalis* if air is excluded. 3. Forms substitution-products with *chlorine.* 4. Strong *sulphuric* and *hydrochloric acids* dissolve and decompose it, the mixture turning black.—5. *Dilute acids,* even in the cold, split up acetal into alcohol and aldehyde.—6. A solution of acetal does not give the iodoform reaction, unless it be first acidified (Grodzki, *B.* 16, 512). 7. PCl_5 forms $CH_3.CHCl.OEt$, EtCl and $POCl_3$ (Buchanan, *A.* 218, 38).—8. Heated with glacial HOAc it forms acetic ether, thus:

$$CH_3.CH(OEt)_2 + 2AcOH =$$
$$CH_3CHO + H_2O + 2AcOEt.$$

9. Does not reduce $AgNO_3Aq$.—10. *Chromic mixture* forms acetic acid.—11. Heated with MeOH it is almost completely converted into EtOH and $CH_3CH(OMe)_2$.—12. Heated with PrOH it is mostly unchanged, but some $CH_3.CH(OEt)(OPr)$ and some $CH_3CH(OPr)_2$ are formed.—13. Heated with *iso-amyl alcohol* it behaves as in 12.

References.—Homologues of acetal are described under the aldehydes, to which they correspond. Bromo- and chloro-acetals are described under bromo- and chloro-acetic aldehyde. For oxy-acetal *v.* glycollic aldehyde.

ACETALDEHYDE *v.* ALDEHYDE.

ACETAMIDE C_2H_5NO *i.e.* NH_2Ac or $CH_3.CO.NH_2$.—Amide of acetic acid. M.w. 59. [83°] (Hofmann, *B.* 14, 2729) (222° cor.). S.G. $_4$ 1·159 (Schröder, *B.* 12, 562). R_∞ 24·35 in a 34-p.c. aqueous solution (Kanonnikoff, *J. pr.* [2] 31, 347). Discovered by Dumas, Malaguti, and Leblanc in 1847 (*C. R.* 25, 657).

Formation.—1. By heating ethyl acetate with strong aqueous ammonia at 120°

$$AcOEt + NH_3 = AcNH_2 + HOEt.$$

2. By action of ammonia on acetic anhydride:

$$Ac_2O + 2NH_3 = NH_2Ac + AcONH_4.$$

3. By distillation of ammonic acetate:

$$AcONH_4 = AcNH_2 + H_2O \text{ (Kundig, } A. \text{ 105, 277).}$$

4. When dry NaOAc (580 g.) is distilled with NH_4Cl (225 g.) very little acetamide (70 g.) is got: the distillate is chiefly NH_3 and acid ammonic acetate, which boils at 145°.

Preparation.—1. Acetic ether and aqueous ammonia are left in a closed vessel until the ether has disappeared. The product is distilled.—2. Glacial acetic acid (1 kilo.) is saturated with dry NH_3 and the product distilled in a current of dry NH_3. Above 190° acetamide (460 g.) comes over; the first distillate (below 190°) is treated in the same way: it gives more acetamide (170 g.). A third repetition of this operation gives more acetamide (110 g.). Total yield: 740 g. (Keller, *J. pr.* [2] 31, 864).—3. Ammonic chloride and sodic acetate are heated in an enamelled iron digester for six hours at 230°. The product is distilled (Hofmann, *B.* 15, 981).—4. A mixture of ammonic acetate (20 g.) and acetic anhydride (26 g.) yields on distillation 96 p.c. (12 g.) of acetamide (Schulze, *J. pr.* [2] 27, 512).—5. Ammonic sulphocyanide (1 mol.) is boiled for four days with glacial acetic acid (2½ mols.):

$$NH_4CNS + 2AcOH = 2AcNH_2 + COS + H_2O \text{ (S.).}$$

Purification.—Acetamide can be freed from ammonic acetate by drying over lime (Menschutkin, *J. R.* 17, 259).

Properties.—White hexagonal scales, smelling like excrement of mice. Deliquescent. V. e. sol. water. Conducts electricity and is easily electrolysed.

Reactions.—1. Resolved by distillation with P_2O_5 into water and acetonitrile, C_2H_3N.—2. With P_2S_5 it also yields acetonitrile, giving off H_2S, and leaving a blackish tumefied residue.—3. Heated in dry HCl-gas it yields: *a.* A liquid distillate consisting of acetic acid with a small quantity of acetyl chloride; *b.* A crystalline distillate of $(C_2H_5NO)_2HCl$, and a compound of acetamide and diacetamide $C_2H_5NO.C_4H_7NO_2$, the latter of which may be dissolved out by ether; *c.* A non-volatile residue of acetamidine hydrochloride mixed with sal-ammoniac:

$$2C_2H_5NO + HCl = C_2H_6N_2.HCl + C_2H_4O_2$$

(Strecker, *A.* 103, 328).—4. Acetamide heated in sealed tubes with saturated *hydriodic acid* yields ammonia, acetic acid, and ethane:

$$2C_2H_5NO + 3H_2 = C_2H_4O_2 + 2NH_3 + C_2H_6$$

(Berthelot, *Bl.* [2] 9, 183).—5. With CS_2 at about 210° it gives off H_2S, COS, CO, and probably ethane, leaving ammonium sulphocyanide mixed with undecomposed acetamide:

$$2C_2H_5NO + CS_2 = NH_4.SCN + COS + CO + C_2H_6$$

(Ladenburg, *Z.* [2] 4, 651). *V.* ALDEHYDES.—6. Nascent hydrogen (copper-zinc couple or sodium-amalgam) forms some alcohol and aldehyde (Essner, *Bl.* [2] 42, 98).—7. Heated with NaOEt at 180° it forms ethylamine (Seifert, *B.* 18, 1357).—8. With *ethyl orthoformate* at 180° acetamide yields ethyl alcohol and diacetylformamidine:

$$2NH_2Ac + CH(OEt)_3 = 3EtOH + N_2(CH)Ac_2H.$$

Another reaction, however, takes place at the same time, producing alcohol, ethyl acetate, and formamidine:

$$2NH_2Ac + CH(OEt)_3 =$$
$$EtOH + 2EtOAc + N_2(CH)H_3$$

(Wichelhaus, *B.* 3, 2).—9. Acetamide heated in sealed tubes with *benzaldehyde* is converted into benzylidene-diacetamide:

$$2NH_2Ac + PhCOH = H_2O + PhCH(NHAc)_2.$$

With *aldehyde* in like manner, it yields $MeCH(NHAc)_2$ in large prisms [169°], partly decomposed by distillation, and giving off aldehyde when treated with acids (Tawildarow, *B.* 5, 477). With *anisaldehyde* the compound $C_{12}H_{16}N_2O_3$ is formed in nodular groups of needles [180°], soluble in water, insoluble in alcohol and ether; decomposed by HCl, not altered by boiling with potash (Schuster, *Z.* [2] 6, 681). With *salicylic aldehyde* a yellow neutral body is formed (Credner, *ib.* 80). With *chloral* acetamide unites directly, forming the crystalline compound $C_2H_5NO.C_2HCl_3O$. (*v.* CHLORAL).—10. Heated with mesityl oxide it forms a basic substance, $C_8H_{13}NO$, '*oxy-hydro-collidine.*' A yellowish liquid (175°-180°) (Canzoneri a. Spica, *G.* 14, 349).

Combinations. — Acetamide unites directly with the stronger acids. The *hydrochloride* $(NH_2Ac)_2HCl$ is formed by passing gaseous HCl into its solution in ether-alcohol. Long needles (from alcohol); insol. in ether.—NH_2AcHCl (Pinner a. Klein, *B.* 10, 1896).—The *nitrate*, NH_2AcHNO_3 [98°], separates from a solution of acetamide in strong HNO_3. It is very acid, and is deliquescent. Sl. sol. ether. Gives off CO_2, N_2O and HNO_3 when heated.

Salts.—AcNHAg. Scales.—$(AcNH)_2Hg$. Six-sided prisms [195°]. Both formed by dissolving the oxides in acetamide.—$(AcNH)_2Zn$. From $ZnEt_2$ and acetamide. Amorphous. (Frankland.)

Chloro-acetamides.—The amides of the chloro-acetic acids are described under those acids. *Aceto-chloro-amide* NAcClH [110°] is formed by passing chlorine into fused acetamide, or by pouring aqueous HCl upon aceto-bromo-amide:

$$2NAcBrH + HCl = NAcClH + NAcH_2 + Br_2$$

(Hofmann, *B.* 15, 410). Sol. ether. Split up by HCl into chlorine and acetamide.

Bromo-acetamides *v.* BROMO-ACETIC ACIDS.

Aceto-bromo-amide

NHBrAc [108°]. NHBrAc aq. [70°-80°]. Formed by adding aqueous KOH to a solution of Br (1 mol.) in acetamide (1 mol.). Striated rectangular plates (from ether).

Reactions.—1. Boiled with *water* it forms acetamide, Br, HBrO, methyl-acetyl-urea, and methylamine.—2. Heated with Ag_2CO_3 it forms methyl cyanate:

$$2CH_3CO.NHBr + Ag_2CO_3 =$$
$$2CH_3NCO + 2AgBr + CO_2 + H_2O.$$

3. Boiled with KOHAq it forms HBr, CO_2, and methylamine, the methyl cyanate formed according to the last reaction being decomposed in the usual way.—4. Acetamide and NaOHAq form methyl-acetyl-urea.—5. *Ammonia* reacts violently, thus:

$$3NAcHBr + 5NH_3 = 3NAcH_2 + 3NH_4Br + N_2.$$

6. *Aniline* forms acetanilide and tri-bromo-aniline.—7. *Phenol* gives tri-bromo-phenol and acetamide (Hofmann, *B.* 15, 407).

Salts.—NAcBrNa. Hair-like needles, ppd. by conc. NaOH. $NAcBrNaBr_2aq$. Made by adding conc. NaOH to a mixture of acetamide (1 mol.) and bromine (1 mol.). Rectangular plates. Decomposed by water into NaBr and aceto-di-bromo-amide.

Aceto-di-bromo-amide $NAcBr_2$ [100°]. Made by adding aqueous KOH to a dilute solution of bromine (1 mol.) and bromo-acetamide (1 mol.) (Hofmann, *B.* 15, 413). Golden needles or plates; sol. warm water, alcohol, or ether. Boiled with water, it gives HBrO, NAcBrH, and $NAcH_2$. Potash decomposes it into nitrogen, acetic acid and potassic hypobromite. H. W.

Bromo-chloro-acetamide *v.* CHLORO-BROMO-ACETIC ACID.

Iodo-acetamide *v.* IODO-ACETIC ACID.

Di-acetamide NAc_2H. M.w. 180 [82°] (210°-215°).

Preparation.—1. The ethereal solution of the crystalline compound of acetamide and di-acetamide got by heating acetamide in a current of HCl (*v. Reaction* 3), deposits, when gaseous HCl is passed through it, spicular crystals of acetamide hydrochloride, and the filtrate yields, by evaporation over H_2SO_4, crystals of diacetamide.—2. By heating acetonitrile with glacial HOAc, or acetamide with Ac_2O at 250° (Gautier, *Z.* 1869, 127).—3. By boiling methyl-acetyl-urea with Ac_2O (Hofmann, *B.* 14, 2731).

Properties. — Long needles (from ether). Neutral. V. e. sol. water, v. sol. alcohol or ether. Does not combine with acids, so that HCl gives no pp. in an ethereal solution.

Reactions.—1. By boiling with *acids* or by heating with $ZnCl_2$ it is resolved into acetic acid and acetonitril.—2. Fuming HNO_3 reacts, giving off N_2O. H. W.

Tri-acetamide NAc_3 [79°].—Formed in small quantity when a mixture of acetic anhydride and acetonitrile is heated to 200°, and may be dissolved out by ether after the excess of Ac_2O has been distilled off. White flexible needles [78°-79°]. Neutral. Gently warmed with silver oxide it yields silver acetate; so likewise do acetamide and diacetamide (Wichelhaus, *B.* 3, 847). H. W.

Tri-acet-di-amide $N_2Ac_3H_3$ [212°-217°]. — This is the compound of acetamide and di-acetamide mentioned under acetamide (*Reaction* 3) and di-acetamide (*Preparation* 1).

Di-azo-acetamide *v.* AZO COMPOUNDS.

Ethyl-acetamide *v.* ETHYL-AMINE.

Methyl-acetamide *v.* METHYL-AMINE.

Phenyl-acetamide *v.* ANILINE.

ACET-.—If compounds whose names begin with *acet* or *aceto* are not here described, remove this prefix and look for the remaining word, changing the termination *ide*, if present, into *ine*.

ACETAMIDINE $C_2H_6N_2$ *i.e.* $CH_3.C(NH).NH_2$ *Acediamine, Ethenyl-amidine, Acet-imid-amide* (Strecker, *A.* 103, 328; Hofmann, *B.* 17, 1924).—The hydrochloride of this base is left as a residue when acetamide is distilled in a current of HCl (*v.* ACETAMIDE, *Reaction* 3). The mass is extracted with alcohol, which leaves NH_4Cl behind.

Properties.—When liberated from solutions of its salts, it splits up into ammonia and ammonic acetate.

Salts.—B'HCl: prisms (from alcohol), [165°].
—$(B'HCl)_2PtCl_4$: yellowish-red prisms.
—$B'_2H_2SO_4$: pearly laminæ.

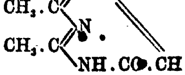
Reactions.—1. The hydrochloride boiled with Ac_2O and NaOAc for 1½ hours forms anhydro-di-acetyl-acet-amidine and anhydro-di-acetyl-acet-amidil (Pinner, *B.* 17, 173).—2. *V.* ACETO-ACETIC ETHER, *Reaction* 25.

Anhydro-di-acetyl-acetamidine $C_6H_9N_3O$ [253°].—Prepared as just stated, the product being treated with aqueous NaOH and the pp. boiled with water, which dissolves the 'amidil,' but not the amidine.

Silky needles (from alcohol). Insol. water, sl. sol. cold alcohol, v. sol. hot alcohol, v. e. sol. dilute acids. Forms a platino-chloride.

Anhydro-di-acetyl-acet-amidil $C_6H_{11}N_3O2aq.$

Possibly



[185°]. Obtained as above. Nodules of small prisms. Loses 2aq over H_2SO_4. Sl. sol. cold water, v. sol. hot water, v. e. sol. alcohol and in dilute acids. Forms a platinum salt.

ACETAMIDOXIM *v.* ETHENYL-AMIDOXIM.

ACETANILIDE *v.* ANILINE *Acetyl derivative.*

ACETIC ACID $C_2H_4O_2$ *i.e.* $CH_3.CO.OH$ or AcOH.—*Methane carboxylic acid, Pyroligneous acid.*—M.w. 60 [16·5°] (Zander), [17·5°] (Sonstadt, *C. N.* 87, 199). (118·29°) (Z.), (117·5°) (Schiff.). *Critical temperature* 321·5° (Pawlewsky, *B.* 16, 2684). S.G. *Solid.* $\frac{0}{0}$ 1·0701 (Z.); $\frac{15}{4}$ 1·0607 (Mendeléeff, *J.* 1860, 7). S.G. *Liquid.* $\frac{12 \cdot 8}{4}$ 1·0576, $\frac{16}{4}$ 1·0543, $\frac{19}{4}$ 1·0503 (Pettersson, *J. pr.* [2] 24, 301); $\frac{20}{4}$ 1·0495 (Brühl); *at boiling-point* ·9325 (Ramsay, *C. J.* 35, 463). V.D. 29·7 at 250° and upwards. C.E. (0°–10°) ·00106 (Z.). H.F.p. 105,290. H.F.v. 104,130. S.H. (between 0° and 100°) ·497. Latent heat of fusion for 1 mol. (at 1·5° to 4·2°) 2619. μ_β 1·3765. R_∞ 20·69 (B.). M.M. 2·525 (Perkin). S.V. 64·3 (R.).

Occurrence.—In the juices of plants, especially of trees, and in certain animal secretions.

Synthesis.—1. From acetylene (*i.e.* from C and H) by converting that hydrocarbon into ethylene by direct addition of hydrogen, then the ethylene into alcohol, and oxidising the alcohol; or more simply by heating acetylene dichloride with aqueous potash at 230° or with alcoholic potash at 100° for ten hours:

$$C_2H_2Cl_2 + 3KHO = C_2H_3O_2K + 2KCl + H_2O$$

(Berthelot, *Z.* [2] 5, 683).—2. When a mixture, 1 vol. acetylene and 2 vols. air, is exposed to daylight over dilute potash-lye, the acetylene is slowly oxidised to acetic acid, which is absorbed by the alkali: $C_2H_2 + O + KOH = C_2H_3O_2K$ (Berthelot, *A. Ch.* [4] 23, 212).—3. From sodium-methyl and carbonic acid:

$$CH_3Na + CO_2 = CH_3.CO_2Na$$

(Wanklyn, *A.* 111, 234).—4. By boiling acetonitrile (methyl cyanide) with potash:

$$CH_3CN + KOH + H_2O = CH_3CO_2K + NH_3$$

(Frankland a. Kolbe, *A.* 65, 298).—5. By passing CO over sodium methylate at 160°:

$$CH_3ONa + CO = CH_3CO_2Na$$

(Fröhlich, *A.* 202, 294).

Formation.—1. By dry distillation of organic bodies, especially wood.—2. By the action of atmospheric oxygen, chromic acid, nitric acid, hypochlorous acid, and other oxidisers, on alcohols and other organic bodies, especially under the influence of ferments which act as carriers of oxygen.—3. By the action of KOH or NaOH at a high temperature on various organic bodies, *e.g.* tartaric, citric, and malic acids, sugar, alcohol, &c.—4. In various processes of fermentation and putrefaction (*J.* 1878, 1017, 1019, 1023).

Preparation.—1. By oxidation of ethyl alcohol, the alcohol being first converted into aldehyde: $C_2H_6O + O = H_2O + C_2H_4O$, and the aldehyde then oxidised to acetic acid. The oxidation may be effected:

a. By the influence of *spongy platinum.* If a tray containing this substance be placed over a dish containing a little alcohol, the whole being covered with a bell-glass open below, as well as at the top, on gently warming the dish the alcohol will be rapidly oxidised, acetic acid condensing in abundance on the inside of the jar. Much of the alcohol is, however, converted into aldehyde and lost by volatilisation.

b. Under the influence of *ferments.* This is the ordinary process of making vinegar from alcoholic liquids, wine being generally used for the purpose in France and Germany, and malt in England. The most favourable temperature is 25°–30°. The experiments of Pasteur have shown that the oxidation of alcohol in the ordinary process of vinegar-making depends essentially on the presence of a fungoid plant called *Mycoderma vini, Mycoderma aceti,* or 'mother-of-vinegar,' and is invariably preceded by its development on the surface of the liquid. It appears to act like platinum-black, as a carrier of oxygen. The plant may be sown on the surface of the liquid by introducing a small portion of it from another vinous liquid already in the fermenting state, or by simply exposing the liquid to the air in which the germs of this fungus, as of many others, are always floating. Like all other plants, it requires food for its development, and this it finds in the albuminous matter and mineral salts contained in ordinary vinous liquors. If these are absent the plant cannot grow, and acetification cannot take place. Thus, pure aqueous alcohol may be exposed to the air for any length of time without turning acid, because the germs of the mycoderma which fall into it from the air remain barren for want of nutriment. Moreover, pure aqueous alcohol may be acetified without the aid of any albuminous matter, provided the mycoderma have access to it, and be supplied with the nitrogen and saline matters necessary for its growth. Pasteur has in fact shown that this nutriment may be supplied in the form of alkaline and earthy phosphates and ammonium phosphate, the latter furnishing the nitrogen. Under these circumstances the mycoderm grows, though less quickly than in ordinary vinous liquids, and the alcohol is slowly converted into acetic acid. If the mycoderma be allowed to remain in the liquid after the acetification is complete, the whole of the acetic acid may be destroyed and the liquid rendered perfectly neutral. (Pasteur, *Études sur le Vinaigre*, Paris, 1868; also *Annales Scientifiques de l'École normale supérieure*, tome i. 1864; *Bl.* 1861, p. 94; *J.* 1861, 726.)

Malt Vinegar is prepared from a fermented wort obtained by mashing malt, or a mixture of malt and raw barley, with water, as in brewing.

Quick Vinegar Process.—The oxidation of the alcoholic liquor may be greatly accelerated by allowing it to trickle down in a fine shower over chips of wood covered by the mycoderma, and exposed to an upward current of air.

Wood Vinegar—Pyroligneous Acid.—The greater part of the acetic acid now used in arts and manufactures is obtained by the destructive distillation of wood. The wood is heated in large iron cylinders connected with a series of condensers. The watery liquid which condenses in the receivers, consisting of water, tar, methyl alcohol or wood-spirit, methyl acetate and acetic acid, is redistilled after separation of the tar, the wood-spirit passing over among the first portions of the distillate and the acetic or pyroligneous acid afterwards. The acid thus obtained is coloured and has a strong tarry flavour, not removable by distillation. To purify it, the crude liquor is saturated with lime, which removes part of the tarry matter, the rest remaining in solution with the calcium acetate. The liquid, clarified by repose or by filtration, is evaporated in an iron pot to half its bulk, and mixed with enough hydrochloric acid to give a slight acid reaction, whereupon the greater part of the tarry matter separates, and may be skimmed off the surface. The hydrochloric acid also decomposes certain compounds of lime with creosote and other volatile substances, which may then be expelled by heat. The calcium acetate thus purified is completely dried and distilled with hydrochloric acid. The density of the acetic acid thus obtained is about 1·06. If it contains hydrochloric acid it may be purified by redistillation with addition of a small quantity of sodium carbonate, or, better, 2 or 3-p.c. potassium dichromate, this latter at the same time destroying certain organic impurities which give the acid a peculiar odour (Völckel, *A.* 82, 49). Crude wood vinegar contains small quantities of propionic, *n*-butyric, *n*-valeric, and two crotonic acids (Grodzki a. Krämer, *B.* 11, 1356).

Crystallisable or *Glacial Acetic Acid* —the pure acid, $C_2H_4O_2$, so-called because it crystallises at ordinary temperatures—is obtained: 1. From the ordinary aqueous acid by fractional distillation, repeated till the residue solidifies on cooling. 2. By distilling certain dry metallic acetates with strong sulphuric acid or with hydrogen potassium sulphate,

$$2C_2H_3KO_2 + H_2SO_4 = K_2SO_4 + 2C_2H_4O_2;$$
$$\text{and } C_2H_3KO_2 + HKSO_4 = K_2SO_4 + C_2H_4O_2.$$

3. Together with acetone and other products, by dry distillation of cupric acetate (*Spiritus Æruginis* or *Sp. Veneris*).

Physical Properties.—The solid acid forms prismatic or tabular crystals. The liquid acid is transparent, colourless, and mobile. Vapour-density at 250° and upwards is 2·08 (air = 1) or 29·7 (H = 1), which is nearly half the molecular weight of the acid, showing that at these high temperatures the vapour exhibits the normal condensation. But at temperatures nearer to the boiling-point the density of the vapour is much greater, showing a condensation to $\frac{3}{2}$ vol. or even less (Cahours, *C. R.* 19, 771; 20, 51). The pressure of the vapour of solid acetic acid is 1·3 mm. at −5·7°, 2·0 mm. at 0°, and 9·5 mm. at 16·4°; the vapour-pressure of liquid acetic acid being 3·2 mm. at 0°, 6·3 mm. at 10°, 11·8 mm. at 20°, 19·9 mm. at 30° (Ramsay a. Young, *C. J.* 47, 45).

Glacial acetic acid has a pungent sour taste and odour and blisters the skin. It does not redden litmus paper *per se*, but reddens it strongly when mixed with water. It does not attack $CaCO_3$ until water is added. It is hygroscopic.

Aqueous Acid.—Acetic acid mixes with water in all proportions. The density of the aqueous acid does not vary in proportion to the amount of real acid present; and consequently the strength of any sample cannot be inferred from its density, but must be determined by titration with standard alkali. The following table has been constructed in this manner by Oudemans (*Fr.* 5, 452) for the temperatures 0°, 15°, and 40°.

Density of Aqueous Acetic Acid (Oudemans).

$C_2H_4O_2$ p. c.	Density at 0°	at 15°	at 40°

The maximum density corresponds at 0° to about 81 p.c., and at 40° to about 76 p.c. Ortho-acetic acid, $CH_3C(OH)_3$, would contain 77 p.c. of HOAc.

Reactions.—1. Vapour inflammable, burning with blue flame to water and CO_2.—2. Partly decomposed by passing through a red-hot tube yielding carbon and combustible gases, together with acetone, benzene, phenol, and naphthalene (Berthelot, *A.Ch.* [3] 33, 295).—3. Dropped upon hot $ZnCl_2$ it gives CO, CO_2, C_2H_4, C_3H_6, isobutylene, and a little CH_4 (Lebel a. Greene, *Am.* 2, 26).—4. Passed over *zinc dust* at 300°-350° it gives hydrogen, acetone, CO, and some propylene (Jahn, *M.* 1, 683).—5. Mixes with strong *sulphuric acid* without evolution of gas, but the mixture becomes hot, and if further heated gives off CO_2 mixed with SO_2. Dissolves SO_3 without giving off gas, forming sulpho-acetic acid. Not sensibly altered by *nitric acid.*—6. *Periodic acid* converts it into carbonic or formic acid, with formation of iodic acid and separation of iodine.—7. With *chlorine* in sunshine it forms mono- and tri-chloro-acetic acids (*q. v.*), the one or the other predominating according as the acetic acid or the chlorine is in excess.—8. Heated with *bromine* in a sealed tube it forms mono- and di-bromo-acetic acids. Not acted upon by *iodine*, even in sunshine.—9. With PCl_5 it forms AcCl, HCl, and $POCl_3$. With PCl_3 it reacts thus: $3AcOH + 2PCl_3 = 3AcCl + P_2O_3 + 3HCl$.—10. With P_2S_5 the products are thio-acetic acid and phosphoric oxide: $5AcOH + P_2S_5 = P_2O_5 + 5AcSH$.—11. With chromyl dichloride CrO_2Cl_2 it forms the compound $Cr_3O_7(C_2H_3O_2)_{10}8H_2O$ (Etard, *A. Ch.* [5] 22, 286).

Detection.—The solution supposed to contain acetic acid or an acetate is acidified with H_2SO_4 and distilled. The distillate, if acid, is neutralised with KOH and should then give the following tests: (1) $FeCl_3$ a brown-red colour, and a pp. on boiling. (2) $AgNO_3$ a white flocculent pp., sol. hot water, separating in spangles when the solution cools. (3) Evaporate to dryness, mix with As_2O_3 and heat: a disgusting odour of cacodyl is perceived.

Acetic Acid Dibromide $C_2H_4O_2.Br_2$ [37°] is formed on treating acetic acid with bromine in presence of a small quantity of carbon bisulphide. Orange-red needles or thick roseate prisms, very deliquescent; dissolving in water with great fall of temperature and separation of bromine, in alcohol, benzene, and glacial acetic acid with partial formation of substitution-products. At 100° dissociation first takes place, but finally HBr and $C_2H_3BrO_2$ are formed.

Compounds of acetic acid with Br and HBr. On adding bromine to well-cooled glacial acetic acid saturated with HBr, the whole solidifies to a mass of thick, rather large, tabular, crystals, which when dried have the composition $(C_2H_4O_2)_2Br_2HBr$; they fume in the air, melt and decompose at + 8°, and are decomposed by water and by potash-lye, yielding $(C_2H_4O_2)_2.Br_2$ and $KBrO_3$. Heated in a sealed tube, they yield bromacetic acid (Steiner, *B.* 1874, 184). The compound $(C_2H_4O_2)_2Br_2.HBr$ has also been prepared by Hell a. Mühlhäuser (*B.* 1878, 241), who by using larger quantities of bromine have further obtained $(C_2H_4O_2)_4Br_6(BrH)_2$ in radiate groups of hard roseate crystals, which may be dried in the lime exsiccator.

Acetates.—Acetic acid is monobasic, the general formula of its normal salts being:

$$R^{(n)}(CH_3.COO)_n = R^{(n)}A'_n$$

the symbol $R^{(n)}$ denoting an *n*-valent radicle metallic or alkylic, and A′ standing for $C_2H_3O_2$.

METALLIC ACETATES.—The normal acetates all dissolve in water, and most of them readily. The least soluble are the silver and mercury salts, so that solutions of other acetates added to mercurous nitrate or silver nitrate throw down white shining scales of mercurous or silver acetate. But for the most part acetates are formed not by precipitation, but by the action of acetic acid on metallic oxides or carbonates; many carbonates, however, those of barium and calcium for example, are not decomposed by acetic acid in its most concentrated state. All acetates are decomposed by heat, most of them yielding carbon dioxide, acetone and an empyreumatic oil. Those which are easily decomposed, and likewise contain bases forming stable carbonates, are almost wholly resolved into acetone and carbonate, *e.g.*:

$$Ba(O.CO.Me)_2 = COMe_2 + BaCO_3.$$

Those which, like the potassium and sodium salts, require a higher temperature to decompose them, yield more complex products, but always a certain quantity of acetone. Among the products are found methylethyl ketone and methyl propyl ketone, together with *dumasin* $C_6H_{10}O$ (Fittig, *A.* 110, 17). Acetates containing weaker bases give off part of the acetic acid undecomposed, the remaining portion being resolved into acetone and carbonic anhydride, or if the heat be strong, yielding empyreumatic oil and charcoal: the residue consists sometimes of oxide, sometimes, as in the case of copper and silver, of reduced metal; in this case part of the acetic acid is burnt by the oxygen abstracted from the metal. The decomposition of silver acetate may be expressed by the equation:

$$4CH_3.CO_2Ag = 3CH_3.CO_2H + CO_2 + C + 4Ag$$

(Iwig a. Hecht, *B.* 19, 238). Acetates heated with a large excess of fixed caustic alkali, are resolved at a temperature below redness into marsh gas and alkaline carbonate, *e.g.*:

$$KC_2H_3O_2 + KOH = K_2CO_3 + CH_4.$$

Acetates distilled with sulphuric acid and alcohol yield ethyl acetate. The acetates of the alkali-metals, and probably others also, treated with phosphorus oxychloride, yield acetyl chloride, together with a tribasic phosphate:

$$3NaOAc + POCl_3 = 3AcCl + Na_3PO_4.$$

Many acetates may be decomposed by water into acetic acid and metallic oxide. This decomposition in the case of aluminic and ferric acetates occurs at 100°, while at 175° the acetates of Mn, Co, Ni, Zn, Ur, Cu, and Ag, as well as ferrous and mercuric acetates, are slowly decomposed (Riban, *C. R.* 93, 1140).

Aluminium Acetates.—The *normal salt* AlA'_3 exists only in solution, being decomposed on evaporation. The solution, which is much used as a mordant in dyeing and calico-printing, and is called 'red liquor' because it yields madder reds and pinks, may be formed by dissolving freshly precipitated aluminium hydroxide in strong acetic acid, or by precipitating a solution of normal aluminium sulphate with lead acetate:

$$Al_2(SO_4)_3 + 3PbA'_2 = 3PbSO_4 + Al_2A'_6.$$

When quickly evaporated at a low temperature, by spreading it out in thin layers on glass or porcelain, it leaves a soluble basic acetate:

$$Al_2O_3.2C_4H_6O_3.4H_2O \text{ or } Al_2O(AcO)_4.4H_2O,$$

forming a gummy mass perfectly soluble in water; but, if heated, or left to evaporate at ord. temp., it deposits insoluble basic salts, containing in the first case two, and in the second five molecules of water, instead of four. The soluble acetate exposed in dilute solution to the temperature of boiling water for several days, undergoes a remarkable change, the whole or nearly the whole of the acid being expelled and a peculiar modification of alumina remaining dissolved (*v.* ALUMINIUM) (Walter Crum, *C. J.* 6, 216). A dilute solution of aluminic acetate, free from alkali, may be boiled without a pp. being formed (Reinitzer, *M.* 3, 259).

Ammonium Acetates.—The normal salt NH_4A' [89°], obtained by saturating glacial acetic acid with dry ammonia-gas, is white, odourless, extremely soluble, and difficult to crystallise, its aqueous solution when evaporated giving off ammonia and leaving the acid salt (Berthelot, *Bl.* 22, 440; Smit, *Bl.* 24, 539; Bahrmann, *J. pr.* [2] 27, 296). When distilled with phosphoric anhydride it loses 2 mol. water, and gives off acetonitrile $C_2H_3N = NH_4C_2H_3O_2 - 2H_2O$. The aqueous solution known in the Pharmacopœia as *Spiritus Mindereri* is prepared by saturating aqueous acetic acid with ammonia or ammonium carbonate. The *acid salt* $NH_4HA'_2$ (145°) is obtained as a crystalline sublimate with evolution of ammonia by heating powdered ammonium chloride with potassium or calcium acetate (*v.* ACETAMIDE). When commercial ammonium acetate is dissolved in its own weight of glacial acetic acid, an acid salt is obtained in long needles, having the composition $2NH_4A'3HA'$ (Berthelot, *Bl.* 24, 107).

Barium Acetate BaA'_2aq, prepared by decomposing the carbonate or sulphide with acetic acid, is obtained, on evaporating the solution at a gentle heat, in flattened prisms; and on cooling to 0°, in monoclinic prisms, BaA'_23aq. The crystals dried at 100° yield the anhydrous salt as a white powder, resolved at a high temperature into barium carbonate and acetone. S.G. (of BaA'_2aq) 2·02; (of BaA'_2) 2·47 (Schröder). V. e. sol. water, insol. alcohol.

Acid Salts.—$BaA'_2HA'2aq$.—$BaA'_22HA'2aq$. (Villiers, *Bl.* 30, 177; *C. R.* 85, 1234).

Double Salt.—$BaA'(NO_3)4aq$ (Lucius, *A.* 103, 113).

Bismuth Acetate separates in micaceous laminæ from a warm mixture of bismuth nitrate and potassium acetate. Acetic acid mixed with a solution of bismuth nitrate prevents the precipitation of that salt by water.

Cadmium Acetate CdA'_23aq. — Monoclinic prisms. V. e. sol. water, deliquescent and difficult to crystallise (Hauer, *Sitz. B.* 16, 131). S.G. 2·01 (dry, 2·34, Schröder).

Calcium Acetate CaA'_2aq. Small efflorescent needles. V. sol. water, sl. sol. alcohol. S.G. of aqueous solutions of CaA'_2 at 17·5° (Franz, *J. pr.* [2] 5, 298):

P.C.	S.G.	P.C.	S.G.	P.C.	S.G.
1	1·0066	11	1·0527	21	1·0925
3	1·0198	13	1·0597	23	1·1027
5	1·0330	15	1·0666	25	1·1130
7	1·0394	17	1·0750	27	1·1248
9	1·0458	19	1·0834	29	1·1366

Calcic acetate splits up on distillation into $CaCO_3$ and acetone.

Acid salt $CaA'_2HA'1\frac{1}{2}aq$. Hygroscopic.

Double salt CaA'_2CaCl_210aq. Monoclinic prisms, permanent in air.

Cerous Acetate $Ce_2A'_63aq$ forms radiate groups of small needles, which become anhydrous in dry air without losing their crystalline form; after drying at 115° they carbonise at a higher temperature without fusing, and when strongly heated leave a residue of cerous oxide (Large, *J. pr.* 82, 129).

Chromium Acetates.—The *chromous salt* CrA'_2aq, obtained from the chloride by decomposition with potassium or sodium acetate, forms red transparent crystals which when moist absorb oxygen very rapidly from the air, sometimes taking fire (Peligot, *A. Ch.* [3] 12, 541).—*Normal Chromic Acetate* $Cr_2A'_62aq$ is obtained by evaporating a solution of chromic hydroxide in acetic acid, as a green crystalline mass, insoluble in alcohol. Its aqueous solution, green by reflected, red by transmitted light, is not decomposed either by boiling or by addition of lime-water; but ammonia throws down from it a green precipitate of chromic hydroxide, soluble in excess (H. Schiff, *A. Ch.* [3] 71, 140; Schützenberger, *Bl.* [2] 4, 86). The solution of the normal acetate heated for several days with excess of chromic hydroxide loses its acid reaction, and yields by evaporation a green powder soluble in water, consisting of a basic acetate $Cr_2A'_4(OH)_2$ Schiff, *A.* 124, 168).

Chromic Diacetotetrachloride, $Cr_2A'_2Cl_4$ is obtained by dissolving Cr_2OCl_4 in strong acetic acid. It is an unstable salt, which gives off acetic acid when heated above 100°. The chlorine is but very slowly precipitated from it by silver nitrate at ordinary temperatures, but, on the other hand, the salt easily yields acetic ether when heated with sulphuric acid and alcohol (Schiff). — *Chromic Diaceto-sulphate* $Cr_2A'_2(SO_4)_2$, obtained by dissolving chromic disulphate in acetic acid, is a crystalline salt which becomes anhydrous at 100°, and gives off acetic acid at a higher temperature (Schiff).— *Chromic Pentaceto-nitrate* $Cr_2A'_5NO_3 4aq$ is obtained by mixing a solution of chromic hydroxide in a slight excess of acetic acid with a solution of the same quantity of chromic hydroxide in the exact quantity of nitric acid required to dissolve it. The concentrated solution, when left to itself, deposits an abundant crystallisation of a dark green salt, which may be purified by recrystallisation from water or from glacial acetic acid. It forms dark green bulky laminæ, which give off nitrous fumes at 100°, the chromium being at the same time converted into trioxide. (Schützenberger).

Cobalt Acetate $CoA'_2 4aq$.—Red needles.

Copper Acetates.—The *cuprous salt* $Cu_2A'_2$ sublimes towards the end of the distillation of normal cupric acetate. According to Berzelius, it is contained in green verdigris and sublimes on distillation. Soft loose white flakes which redden litmus and have a caustic astringent taste. Decomposed by water, yielding normal cupric acetate and cuprous oxide.

The *normal cupric salt* CuA'_2aq is prepared by dissolving cupric oxide or common verdigris in hot acetic acid, or by decomposing normal lead acetate with cupric sulphate. Dark-green monoclinic crystals (S.G. 1·9), efflorescent, soluble in 14 pts. cold and 5 pts. boiling water, sparingly also in alcohol, insoluble in ether. The solution boiled with grape-sugar yields a red precipitate of cuprous oxide. Cupric acetate crystallised at a temperature near 8° yields crystals containing $CuA'_2 5H_2O$. A solution of cupric acetate heated in a sealed tube at 200° forms crystallised cuprous oxide and cupric glycollate (Caseneuve, *C. R.* 89, 525).

Acid Cupric Acetate $CuA'_2HA'aq$ (Villiers, *C. R.* 85, 1234).

Basic Cupric Acetates.—These salts may be regarded as compounds of the normal salt with CuO, as compounds of Ac_2O with CuO, or, by taking account of water of crystallisation, as aceto-hydrates, *e.g.*:

Sesquibasic: $CuO.2CuA'_2.6aq =$
$3CuO.2Ac_2O.6Aq = 2CuA'(OH).CuA'_2.5aq$.

Dibasic: $CuO.CuA'_2 6Aq = 2CuO.Ac_2O.6aq = 2(HO.CuA')5aq$.

Tribasic: $2CuO.CuA'_2 2aq = 3CuO.Ac_2O.2aq = 2(HO.CuA')Cu(OH)_2$.

They are contained in *common verdigris* (*vert-de-gris*), a substance obtained by exposing plates of copper to the air in contact with acetic acid, and much used as a pigment and as a mordant in dyeing wool black. There are two varieties of this substance, the blue and the green, the former consisting almost wholly of dibasic cupric acetate, the latter of the sesquibasic salt mixed with smaller quantities of the dibasic and tribasic acetates. The *dibasic salt* or *blue verdigris* is prepared at Montpellier and in other parts of the south of France, by exposing copper to the air in contact with fermenting wine-lees. The same compound is obtained by exposing copper plates to damp air in contact with normal cupric acetate made into a paste with water. It forms delicate, silky, blue crystalline needles and scales, which yield a beautiful blue powder. They contain 6 mol. water, which they give off at 60°, and are then converted into a green mixture of the monobasic and tribasic salt.

Green Verdigris is manufactured at Grenoble by frequently sprinkling copper plates with vinegar in a warm room; and in Sweden by disposing copper plates in alternate layers with flannels soaked in vinegar.

Calcio-cupric Acetate $CaA'_2CuA'_2 8aq$, obtained by heating a mixture of 1 mol. CuA'_2 and 1 mol. $Ca(OH)_2$ with 8 pts. water and sufficient acetic acid to dissolve the precipitated CuO, and evaporating the filtrate at 25°–27°, crystallises in large blue square prisms, slightly efflorescent, giving off acetic acid and falling to powder at 75°; readily soluble in water. Another calcio-cupric acetate often exists in crystallised verdigris.

Cupric Aceto-arsenite $CuA'_2.3Cu(AsO_2)_2$.—*Schweinfurt green*, *Imperial green*, *Mitis green*, and when mixed with gypsum or heavy spar, *Neuwcider green*, *Mountain green*. Used as a pigment, and prepared on the large scale by mixing arsenious acid with cupric acetate and water. 5 pts. of verdigris are made up to a thin paste, and added to a boiling solution of 4 pts. or rather more of arsenious acid in 50 pts. of water. The boiling must be well kept up, otherwise the precipitate assumes a yellow-green colour, from formation of copper arsenite; in that case acetic acid must be added, and the boiling continued a few minutes longer. The precipitate then becomes crystalline, and acquires the fine green colour peculiar to the aceto-arsenite. The salt is insoluble in water, and when boiled with water for a considerable time, becomes brownish and gives up acetic acid. Acids abstract the whole of the copper, and aqueous alkalis first separate blue cupric hydroxide, which when boiled with the liquid is converted into cuprous oxide, an alkaline arsenate being formed at the same time.

Didymium Acetate $DiA'_3 4aq$. S.G. 1·882. S. V. S. 207·8.—DiA'_3aq. Red needles. S. G. 2·237. S.V.S. 150·6 (Clève, *Bl.* [2] 43, 365).

Erbium Acetate $EbA'_3 4aq$.—Isomorphous with didymium acetate (Thomsen, *B.* 6, 712).

Iron Acetates.—*Ferrous acetate* $FeA'_2 4aq$, obtained by dissolving iron or ferrous sulphide in strong acetic acid, separates on concentration in small colourless silky needles, which dissolve readily in water and quickly absorb oxygen from the air.

Ferric Acetate is not known in the solid state as a salt of constant composition. The dark red solution of ferric hydroxide in acetic acid (*Liquor ferri acetici*) contains a basic salt. The following *basic ferric acetates* have been distinguished: $Fe_2A'_4(OH)_2$ obtained by dissolving at 50° the ferric hydroxide from 1 pt. Fe in 10 pts. acetic acid of 30 p.c. and evaporating at 70°. Amorphous, soluble in alcohol and water (Oudemans, *J.* 1858, p. 282).—$Fe_2A'_3(OH)_3$, probably contained in the red solution formed on treating $Fe_2A'_3(OH)Cl_2$ (*infra*) with silver oxide. Becomes syrupy in a vacuum but does not crystallise; decomposes quickly at ord. temp., forming an ochreous jelly (Scheurer-Kestner).—$Fe_2A'_2(OH)_4 2Fe_2O_3$ is the ochreous deposit formed in a solution of ferrous acetate exposed to the air. Other basic salts appear to be formed in the decomposition of the normal salt by heat or otherwise. A solution of ferric acetate, quite free from other salts, is not ppd. by boiling (Reinitzer, *M.* 3, 257).

Acetonitrates (Kestner, *A. Ch.* [3] 63, 422; 68, 472; *J.* 1861, 307).—Formed by mixing solutions of ferric nitrate and acetate in various proportions, or by dissolving ferric hydroxide in various mixtures of acetic and nitric acids. Mostly very unstable, decomposed by boiling with water.—$FeA'_3(OH)_2NO_3$ forms deep red flattened prisms, very soluble in water and in alcohol, insol. in ether.—$FeA'_4(OH)NO_3 4aq$ forms red-rown rhombic prisms, sol. in water and alcohol, lecomposing on slight rise in temperature. The *liformi-diaceto-nitrate* $Fe_2(COH)_2(OAc)_2(NO_3)_2$ s very soluble in water and alcohol, insol. in ether, very unstable.

Acetochlorides. — $Fe_2A'_3Cl_2(OH)3aq$ is obtained on cautiously adding nitric acid to a solution of $FeCl_2$ in acetic acid at 86°; also when ferric hydroxide (1 mol.), acetic acid (1 mol.), and hydrochloric acid (1 mol.) are digested together at 40° for two or three days. Very hard crystals, black by reflected, red by transmitted light, very soluble in water. With silver oxide they yield ferric triacetate (K.; Schiff, *A. Ch.* [3] 66, 136).—$Fe_2A'_4Cl_2$, obtained by dissolving 1 mol. ferric hydroxide in a mixture of HCl (2 mol.) and $C_2H_4O_2$ (4 mols.), or by oxidising ferrous chloride dissolved in very strong acetic acid with nitric acid. Yellowish-red crystals, sol. in water and in alcohol, easily resolved into acetic acid and $Fe_2A'_3(OH)Cl_2$. Heated at 50° for twelve hours with silver nitrate, it is converted into *ferric tetraceto-dinitrate*:

$$Fe_2A'_4Cl_2 + 2AgNO_3 = 2AgCl + Fe_2A'_4(NO_3)_2.$$

Lanthanum Acetate $LaA'_3 1\frac{1}{2}aq$. — Small needles (Clève, *Bl.* [2] 21, 196).

Lead Acetates, or *Plumbic Acetates.*—The *normal salt* $PbA'_2 3aq$, *Sugar of lead*, *Sel saccharum Saturni*, [75°] S.G. 2·5.—Prepared by dissolving lead oxide or carbonate in acetic acid (Wichmann, *J.* 1853, 738).

Properties.—Monoclinic efflorescent crystals, easily soluble in water and in spirit of ordinary strength, insoluble in cold absolute alcohol, completely dehydrated by prolonged boiling with absolute alcohol. An aqueous solution saturated at 15° contains 387·623g. salt in a litre, and has a density of 1·2367 (Michel a. Kraft, *J.* 1854, p. 296).

Density of the Aqueous Solution at 14°.
(Oudemans, *Fr.* 7, 419; *J.* 1868, 29.)

Cryst. Salt p.c.	Density	Cryst. Salt p.c.	Density
1	1·0057	20	1·1399
5	1·0317	25	1·1808
10	1·0659	30	1·2248
15	1·1018	33	1·2525

Normal lead acetate melts at 75°, begins to give off water with a portion of its acid a little above 100°, and is completely dehydrated at 280°. Above that temperature it decomposes, giving off acetic acid, carbonic anhydride, and acetone, and leaving metallic lead very finely divided and highly combustible. The aqueous solution is partially decomposed by the carbonic acid of the air, carbonate of lead being precipitated, and a portion of acetic acid set free, which prevents further decomposition. The solution is not precipitated by ammonia in the cold, but yields crystals of lead oxide when heated with a large excess of ammonia. Normal lead acetate forms crystalline compounds with chloride and peroxide of lead (*Gm.* 8, 310). Bromine added to a solution of the normal salt throws down a brown precipitate of PbO_2, which, if the liquid be warmed, continues to form till 2 at. Br have been added to 2 mol. PbA'_2. The solution then contains lead bromide and acetic acid:

$$2PbA'_2 + 2H_2O + Br_2 = PbO_2 + PbBr_2 + 4HA'$$

(Chapman a. Smith, *C. J.* 22, 185).

Basic Lead Acetates. — $Pb_2A'_3(OH)$, formed by repeatedly drenching the normal salt with absolute alcohol; the residue crystallises from hot absolute alcohol in nacreous six-sided plates, easily soluble in water, sparingly in cold alcohol (Plöchl. *B.* 13, 1647).—$PbA'_2PbO 2aq$. *Lead-vinegar, Acetum Saturni.* Prepared by dissolving litharge in the aqueous normal salt, and evaporating at a gentle heat, whereupon it crystallises in needles. According to Wittstein (*A.* 52, 253) the crystals contain only 1 mol. H_2O. Easily soluble in water and in alcohol of 90 p.c. Reacts alkaline. Decomposed by CO_2. A solution of this salt mixed with alcohol forms *Goulard's lotion.*—$PbA'_2 2PbO aq$, obtained by dissolving PbO in normal lead acetate, or by mixing a solution of the normal salt with ammonia. Crystallises in silky needles, soluble in 5·55 pts. water at 100°, insoluble in absolute alcohol (Payen, *A.* 25, 124; *A. Ch.* [4] 8, 6; Löwe, *J. pr.* 98, 385; *J.* 1866, 235).

An *Aceto-chloride* ClPbA′ is formed by heating recently precipitated lead chloride with normal lead acetate and acetic acid at 160°, and crystallises in monoclinic prisms. Decomposed by water into lead chloride and the more soluble salt PbA'_2ClPbA'. The analogous compounds, BrPbA′ and IPbA′ obtained in like manner, form small monoclinic crystals (Carius, *A.* 125, 87).

Sodio- and *Potassio-plumbic Acetates.*—$PbA'_2NaA'\frac{3}{2}aq$. Monoclinic crystals (Rammelsberg, *J.* 1855, 503).—$PbA'_2 2PbO 4KA'$ is formed on adding potash-lye (S.G. 1·06) with agitation to a boiling solution of normal lead acetate (S.G. 1·25 to 1·30). Crystalline pulp, moderately soluble in water (Taddei, *J.* 1847–8, 548).

Aceto-formate $(CHO_2)Pb_2(C_2H_3O_2)_3 2aq$.

Needles, easily soluble in water, sparingly in alcohol (Plöchl. *B.* 13, 1645).

Lithium Acetates. —LiA'2aq. Rhombic prisms [c. 70°]. Dissolves in less than ⅓ pt. water at 15°; in 4·64 pts. alcohol of density 0·81 at 14° (Fleisch. *Zeitschr. f. Physik*, 4, 108). According to Rammelsberg (*A.* 56, 221), the crystals contain only 1 mol. H_2O.—LiA'HA', obtained by spontaneous evaporation of a solution of the normal salt in glacial acetic acid [99°]. Rotates on water. Under somewhat different circumstances it crystallises in small four-sided plates, containing Aq and melting at 85° (Lescœur, *Bl.* 24, 516).

Magnesium Acetate MgA$'_2$4aq.—S.G. 1·45 (Schröder). Monoclinic, slightly deliquescent, very soluble in water and in alcohol (v. Hauer, *J.* 1855, 501; Patrouillard, *C. R.* 84, 553).

Manganous Acetate MnA$'_2$4aq.—Pale red transparent monoclinic plates, permanent in the air, soluble in 3-3·5 pts. water, also in alcohol. S.G. 1·6 (Schröder).

Acid Salt MnA$'_2$HA'2aq (Villiers, *Bl.* 30, 177).

Manganic Acetate MnA$'_3$2aq.—Brown crystals (Otto, *A.* 93, 372; Christensen, *J. pr.* [2] 28, 14).

Mercury Acetates.—1. Hg$_2$A$'_2$. Obtained by precipitation. Micaceous scales. S. ·75 at 13°. —HgA$'_2$. Brilliant micaceous laminæ. S. 25 at 10°, 36 at 19°, 100 at 100°. Dissolves with partial decomposition in 17·7 pts. alcohol (S.G. ·811) at 19° (*Gm.* 8, 332).—An *aceto-sulphide*, HgA$'_2$HgS, is precipitated, on passing H_2S into a solution of mercuric acetate, as a white crystalline powder.—*Mercuro-diammonium Acetate* N$_2$H$_6$HgA$'_2$H$_2$O. Rectangular plates; easily soluble in water, nearly insoluble in alcohol; smells of acetic acid, and decomposes gradually on exposure to the air (Hirzel, *J.* 1851, 437).

Nickel Acetate.—Apple-green prisms, soluble in 6 pts. cold water, insoluble in alcohol (Tupputi, *A. Ch.* 78, 164).

Potassium Acetates.—*Normal salt* KA'. *Terra foliata tartari.*—S. 188 at 2°; 229 at 13·9°; 492 at 62° (Osann). A boiling saturated solution contains 8 pts. salt to 1 pt. water, and boils at 169° (Berzelius). Soluble in 3 pts. cold and 2 pts. hot alcohol. Exists in many plant-juices. White, difficult to crystallise, extremely deliquescent, insoluble in ether. Chlorine passed into its aqueous solution liberates CO_2 and forms a bleaching liquid. On passing an electric current through a concentrated aqueous solution of the salt, hydrogen is evolved at the negative pole, and at the positive a mixture of ethane and CO_2. The principal decomposition is: $2(CH_3.CO_2H) = C_2H_6 + 2CO_2 + H_2$, methyl oxide and acetate being secondary products (Kolbe, *A.* 69, 257). On passing CO_2-gas into a solution of the salt in alcohol of 97-100 p.c., a large quantity of potassium carbonate is thrown down, and ethyl acetate is formed (Pelouze, *A.* 5, 265).

Acid Potassium Acetate KA'HA' is formed when the normal acetate is evaporated with an excess of strong acetic acid, and separates in needles or laminæ, or in long flattened prisms. Very deliquescent; melts at 148°, and decomposes at 200°, giving off pure AcOH. This affords an easy method of obtaining glacial acetic acid. Acid potassium acetate is also formed when the normal salt is distilled with butyric or valeric acid; but neither of these acids decomposes the salt thus produced. Henc when butyric or valeric acid is mixed with aceti acid, a separation more or less complete may b effected by half neutralising the liquid wit potash and distilling. If the acetic acid is i excess, acid potassium acetate alone remains behind, the whole of the butyric or valeric aci passing over, together with the remainder of th acetic acid. If, on the contrary, the other aci is in excess, it passes over unmixed with aceti acid, and the residue consists of potassiun acetate mixed with butyrate or valerate. By repeating the process a certain number of times either on the acid distillate or on the acid separated from the residue by distillation with sulphuric acid, complete separation may be effected Acetic acid, therefore, is an exception to the rule that when a mixture of fatty acids and their potassium salts is boiled the most volatile acids distil over (Liebig, *A.* 71, 355).—KA'2HA' [112°]. S.G. 1·4. Deliquescent plates (Lescœur, *Bl.* 22, 156).

Anhydrous Potassium Diacetate or *Potassium Pyroacetate* $K_2C_8H_{12}O_7 = 2KOAc.Ac_2O$, prepared by dissolving melted KOAc in boiling acetic anhydride, forms colourless needles very soluble in water, less deliquescent than normal potassium acetate. Decomposed by heat, giving off Ac_2O (Gerhardt, *A. Ch.* [3] 37, 317).

Rhodium Acetate RhA$'_3$2½aq (Claus, *J.* 1860, 213).

Rubidium Acetate RbA'.—Plates (Grandeau, *J.* 1863, 184).

Samarium Acetate SmA$'_3$4aq.—S.G. 1·94. S.V.S. 205·6. Yellow crystals (Clève, *Bl.* [2] 43, 171).

Silver Acetate AgA' (S. 1·02 at 14°) separates on mixing the concentrated solutions of $AgNO_3$ and NaOAc. Dissolves in hot water, and on cooling separates as nacreous flexible laminæ. Heated with *iodine* it is resolved into silver iodide, methyl acetate, hydrogen acetate, CO_2, acetylene, and hydrogen (Birnbaum, *A.* 152, 111). When dry, it combines with NH_3, forming AgA'2NH$_3$ (Reychler, *B.* 17, 47).

Sodium Acetates.—NaA'3aq. [58°] (123°). S.G. 1·4. S. 26 at 6°, 42 at 37°, 59 at 48° (Osann). S. (alcohol of S.G. ·8322) 2·1 at 18°. Crystallises with $3H_2O$ in monoclinic prisms, melting below 100°. According to Reischauer (*J.* 1860, 50), the crystals give off the whole of their water in a vacuum at ord. temp. The fused salt in damp air quickly takes up about $7H_2O$, forming a supersaturated solution, whereas the unfused salt takes up from the air only the original $3H_2O$. When the aqueous solution of NaA' turns mouldy, oxygen is absorbed, and small quantities of alcohol and formic acid are produced (Béchamp, *Z.* 6, 438).

The S.G. of solutions containing the following percentages of NaA' is given by Franz (*J. pr.* [2] 5, 297) as follows:

P.C.	S.G.	P.C.	S.G.	P.C.	S.G.
1	1·0058	11	1·0591	21	1·1134
3	1·0174	13	1·0697	23	1·1254
5	1·0292	15	1·0802	25	1·1374
7	1·0390	17	1·0910	27	1·1506
9	1·0488	19	1·1018	29	1·1638

The S.G. of a saturated solution being 1·1842.

Acid Sodium Acetates (Villiers, *Bl.* 29, 153; 30, 175; *C. R.* 85, 1284; Lescœur, *Bl.* 22, 156).—NaA'HA'aq. Cubic (Fehling).—NaA'2HA' or NaA'2HA'aq. Long needles. [127°]—

5NaA'4HA'6aq.—4NaA'HA'11aq.—
5NaA'2HA'13aq.

The three last are, perhaps, mixtures.

Strontium Acetates SrA'_2 ½aq.—Below 15° it crystallises with 4Aq in monoclinic prisms.

An *aceto-nitrate* $NO_3SrA'\frac{3}{2}H_2O$ forms triclinic crystals (Hauer, *J.* 1858, 281; Zepharovich, *J.* 1860, 309). Villiers (*Bl.* 30, 176) describes the following acid acetates:

$SrA'_2HA'2aq$. $3SrA'_24HA'6aq$. $2SrA'_23HA'1\frac{1}{2}aq$.

Thallium Acetates.—*Thallous acetate* TlA'. White silky needles, easily soluble in water and in alcohol, and deliquescent (Crookes, *C. J.* 27, 149).

Acid Salt TlA'HA' [64°] (Lescœur, *Bl.* 24, 516).

Basic Thallic Acetate $TlA'_3 2Tl(OH)_3 1\frac{1}{2}aq$. Colourless plates, readily resolved into acetic acid and thallic oxide.

Tin Acetates.—Tin dissolves slowly in boiling acetic acid, with evolution of hydrogen, and stannous hydroxide dissolves readily in the boiling acid, the solution when evaporated to a syrup and covered with alcohol yielding small colourless crystals. Stannic hydroxide also dissolves in the acid, the solution when evaporated leaving a gummy mass. Stannic chloride forms a crystalline compound with glacial acetic acid.

Uranium Acetates.—*Uranous acetate.* Warty groups of green needles.—*Uranic acetate* or *Uranyl acetate* $UO_2A'_2$, obtained by heating uranic nitrate till it begins to give off oxygen, dissolving the yellowish-red mass, which still contains NO_3H, in warm concentrated acetic acid, and evaporating to the crystallising point. Crystallises from strongly acid solutions in yellow transparent monoclinic prisms, containing $UO_2A'_22aq$, which dissolve in boiling water with separation of UO_3, but are reproduced on evaporating the solution. A weaker solution cooled below 10° deposits quadratic octahedrons of $UO_2A'_23aq$, which give off 1 mol. H_2O at 200°, the rest at 275°. *Double Salts.*—$NH_4A'UO_2A'_23aq$, $NaA'UO_2A'_2$ (regular tetrahedrons), and $KA'UO_2A'_2aq$ (quadratic prisms), are obtained by adding the respective alkaline carbonates to a solution of uranic acetate till a precipitate is formed consisting of alkali-metal uranate, redissolving this in a slight excess of acetic acid, and cooling to crystallisation. The other double salts of the group are formed by boiling the carbonates with uranic acetate till all the UO_3 is precipitated, redissolving in acetic acid and evaporating.—$BaA'_22UO_2A'_26aq$. Small yellow crystalline spangles, easily soluble in water; give off their crystal-water at 275° (Wertheim, *J. pr.* 29, 227).—$CaA'_22UO_2A'_28aq$. Sulphur-yellow rhombic crystals, easily soluble in water, permanent in the air, becoming anhydrous at 200° (Weselsky, *J. pr.* 75, 55).—$CdA'_22UO_2A'_25aq$. Dichroic crystals.—$PbA'_2UO_2A'_2$ 6aq. Tufts of pale yellow needles.—$MgA'_22UO_2A'_2$ 8aq. Rectangular prisms.—$NiA'_22UO_2A'_2$ 7aq. Emerald-green rhombic crystals.—$SrA'_2UO_2A'_2$ 6aq. Sulphur-yellow crystals.—$ZnA'_22UO_2A'_2$ 8aq. Sulphur-yellow crystals, isomorphous with the nickel salt.

$MnA'_2UO_2A'_2$ 6aq. $FeA'_2UO_2A'_2$ 7aq.
$TlA'2UO_2A'_2$ 2aq. $LiA'UO_2A'_2$ 3aq.
$BeA'_2UO_2A'_2$ 2aq. $AgA'UO_2A'_2$ aq.

Zinc Acetate.—ZnA'_2 3aq. [235°-257°] S.G 1·72.—ZnA'_2 [242°] S.G. 1·84.—Monoclinic laminæ. Very soluble in water. May be sublime as ZnA'_2, especially *in vacuo* (Franchimont, B 12, 11). ZnA'_2 may be crystallised, in anhydrous state, from HOAc (Peter a. Rochefontaine *Bl.* [2] 42, 573).

Yttrium Acetate YA'_3 8aq(?).—Isomorphou with the acetates of didymium and erbium (Clève).

ALKYL ACETATES. *Acetic Ethers.*

Methyl Acetate $C_3H_6O_2$ or MeA'. M.w. 74 (55°) at 754·4 mm. (R. Schiff); (56·3°) at 760 mm (Kopp); (57·3°) (Gartenmeister); (57·5°) at 760 mm. (Elsässer, Perkin). S.G. $\frac{0}{0}$ ·9643 (G.) $\frac{0}{4}$ ·9577 (E.); $\frac{15}{15}$ ·9398 (P.); $\frac{20}{4}$ ·9039 (Brühl); $\frac{25}{25}$ ·9286 (P.); $\frac{65}{4}$ ·8825 (S.). V.D. 2·563 (for 2·564). C.E. (0°–10°) ·00133 (G.); ·00136 (E.). S. 33 at 22° (J. Traube). S.V. 83·66 (S.); 83·2 (G.); 83·77 (E.). μ_β 1·3654. R_∞ 28·78 (B.). H.F.p. 96,720. H.F.v. 94,980. M.M. 3·362 at 22° (P.).

Occurrence.—In crude wood-vinegar (Weidmann a. Schweizer, *P.* 43, 593).

Preparation.—1. By distilling 2 pts. wood-spirits with 1 pt. very strong acetic acid and 1 pt. strong sulphuric acid, removing the excess of wood-spirit by means of fused calcium chloride, and rectifying over sodium carbonate (Dumas a. Peligot [1835], *A. Ch.* [2] 58, 46). 2. By heating H_2SO_4 (50 c.c.) and MeOH (50 c.c.) to 140° and running in slowly a mixture of equal parts of MeOH and HOAc (Pabst, *Bl.* [2] 38, 350). 3. By distilling 3 pts. wood-spirit with 14·5 pts. dried lead acetate and 5 pts. strong sulphuric acid, agitating the distillate with milk of lime, treating the supernatant oil with calcium chloride, and rectifying (Kopp, *A.* 55, 181).

Properties. — Colourless fragrant liquid. Soluble in water; mixes in all proportions with alcohol and ether.

Reactions.—1. Aqueous solution only slightly decomposed by boiling.—2. Resolved by caustic *alkalis* into methyl alcohol and acetic acid.—3. When poured on pulverised *soda-lime* it is violently decomposed, with formation of sodium acetate and formate, and evolution of hydrogen.—4. With *sodium* it reacts like ethyl acetate (*q. v.*), yielding as chief products sodium methylate, $NaOCH_3$, and methyl sodio-aceto-acetate, COMe.CHNa.COOMe.—5. Decomposed by strong sulphuric acid, becoming hot, giving off acetic acid, and forming methyl sulphuric acid.

Chloro-methyl Acetate CH_2ClOAc (115° i.V.). S.G. $\frac{14\cdot5}{}$ 1·195. V.D. 3·70 (for 3·74).—Made by passing chlorine into methyl acetate at 10°. An oil. Slowly decomposed by water, quickly by alkalis, giving HCl, HOAc, and formic aldehyde:

$$CH_2Cl(OAc) + 2KOH = CH_2O + H_2O + KCl + KOAc.$$

With alcoholic KOAc it gives methylene acetate, $CH_2(OAc)_2$ *v.* formic aldehyde (L. Henry, *B.* 6, 740).

Di-chloro-methyl Acetate $CHCl_2.OAc$ (145°-148°), S.G. 1·25, is formed by passing dry chlorine through methyl acetate at a gentle heat. Colourless, pungent-smelling liquid. Decomposed slowly by water, quickly by aqueous potash, violently by alcoholic potash, yielding formic, acetic, and hydrochloric acids,

$$CHCl_2(OAc) + 5KOH = CH_2(OK)O + H_2O + 2KCl + KOAc$$

(Malaguti, *A.* 32, 47).

Tri-chlorinated Methyl Acetate $C_3H_3Cl_3O_2$ (145°). Laurent, *A. Ch.* [2] 73, 25.

Per-chlorinated Methyl Acetate $CCl_3.O.CO.CCl_3$. Formed by prolonged action of Cl on methyl acetate *v. tri*-CHLORO-ACETIC ACID.

Ethyl Acetate $C_4H_8O_2$ or EtA′.—*Acetic ether.* M.w. 88. (75·5°–76·5°) at 745·5 mm. (R. Schiff); (77·1°) at 760 mm. (Elsässer); (77·5°) (Gartenmeister). S.G. $\frac{0}{0}$ ·9253 (G.); $\frac{0}{4}$ ·9239 (E.); $\frac{20}{4}$ ·9007 (Brühl); $\frac{15}{15}$ ·9072, $\frac{25}{25}$ ·8971 (Perkin); $\frac{75.5}{4}$ ·8306 (S.) V.D. 3·087 (for 3·079). S.H. ·48. C.E. (0°–10°) ·001263 (E.). S. 6 at 17·5°. S.V. 105·7 (S.); 106·1 (G.); 106·15 (E.). μ_β 1·3771. R_∞ 35·46 (B.). H.F.p. 114,710. H.F.v. 112,290.

Formation.—(Lauragais, *J. d. Sçavans*, 1759, 324; Thenard, *Mém. d'Arcueil*, 1, 153; Dumas a. Boullay, *J. Ph.* 14, 113; Liebig, *A.* 5, 34; 30, 144; Malaguti, *A. Ch.* [2] 20, 367; [3] 162, 58).

1. By heating alcohol with acetic acid or with an acetate and strong sulphuric acid. 2. By distilling calcium or potassium ethyl-sulphate with glacial acetic acid (Liebig).

Preparation.—1. By distilling a mixture of 3 pts. potassium acetate, 3 pts. absolute alcohol, and 2 pts. sulphuric acid; or 10 pts. sodium acetate, 6 pts. alcohol, and 15 pts. sulphuric acid; or 16 pts. dry lead acetate, 4½ pts. alcohol, and 6 pts. sulphuric acid. The acid is first mixed with the alcohol, and the liquid is poured upon the pulverised salt; the mixture is then distilled to dryness, and the product is purified by digestion with calcium chloride and rectification.—2. Frankland a. Duppa prepare ethyl acetate by gradually pouring a mixture of 3·6 kilo. of 97-p.c. alcohol, and 9 kilo. strong sulphuric acid, on 6 kilo. sodium acetate previously fused and dried, leaving the mixture at rest for 12 hours, then distilling and rectifying the distillate (which is free from alcohol and amounts to 6 kilo.) over fused and pulverised calcium chloride. The best mode of mixing the alcohol and sulphuric acid is to pour the alcohol through a narrow glass tube to the bottom of the vessel containing the acid, stirring the liquid continually by means of the tube. It is best to leave the ethyl-sulphuric acid thus formed for 24 hours before pouring it on the sodium acetate. 3. A mixture of alcohol and acetic acid in molecular proportions is allowed to run into sulphuric acid at 130°, whereby ethyl-sulphuric acid is first formed, and this with the acetic acid forms ethyl acetate, which distils over, leaving the sulphuric acid to be further acted on by the alcohol. By this process 10 g. sulphuric acid yield 232 g. ethyl acetate (Eghis, *B.* 6, 1177; Pabst, *Bl.* [2] 33, 350).

Properties.—Colourless fragrant liquid. Soluble in 17 pts. water at ord. temp.; dissolves ·036 pts. of water; freely miscible with alcohol and ether.

Reactions.—1. *Burns* with yellowish flame. 2. By dilute *chromic acid* it is oxidised to acetic acid $C_4H_8O_2 + O_2 = 2C_2H_4O_2$ (Chapman a. Thorp, *C. J.* 19, 484).—3. Permanent in the *air* when dry, but gradually decomposing when moist into alcohol and acetic acid; more quickly in contact with alkalis.—4. Converted by heating with *sulphuric acid* into ethyl oxide and acetic acid; with *hydrochloric acid* into acetic acid and ethyl chloride.—5. The vapour passed over *zinc-dust* at 300°–350° gives acetone, CO, hydrogen and ethylene (Jahn, *B.* 13, 2107).—6. With *lime* in sealed tubes at 250°–280° it yields butyric acid as chief product, calcium acetate and ethylate as intermediate products:

$$2CaO + 2EtOAc = Ca(OAc)_2 + Ca(OEt)_2 = Ca(OH)_2 + Ca(C_4H_7O_2)_2$$

(Lubavin, *Bl.* [2] 34, 679).—7. With *alkaline hydroxides* it yields acetic acid and ethyl alcohol; with the *anhydrous oxides*, acetic acid and a metallic ethylate:

$$2EtOAc + Ba(OH)_2 = Ba(OAc)_2 + 2EtOH; \text{ and}$$
$$2EtOAc + 2BaO = Ba(OAc)_2 + Ba(OEt)_2$$

(Berthelot a. Flourieu, *A. Ch.* [3] 17, 80).—8. With a mixture of *lime-water* and *chloride of lime* (bleaching powder), it yields chloroform (Schlagdenhauffen, *J. Ph.* [3] 36, 190).—9. With alcoholic KHS it forms, on heating, KOAc and H_2S, but no mercaptan (C. Gottig, *J. pr.* [2] 33, 90).—10. With *sodium-ethylate*, forms, at 130°, sodio-aceto-acetic ether.—11. Ethyl acetate heated with *sodium* dissolves the metal, and the whole solidifies to a crystalline mass of sodium ethylate and ethyl sodio-aceto-acetate $C_6H_9NaO_3$. The reaction is either

$$2(C_2H_5.O.Ac) + Na_2 = NaOC_2H_5 + C_6H_9NaO_3 + H_2;$$
$$\text{or } 3(C_2H_5.O.Ac) + Na_4 = 3NaOC_2H_5 + C_6H_9NaO_3.$$

The quantity of hydrogen evolved varies considerably according to the temperature and pressure at which the reaction takes place, and the proportions of the materials used; sometimes no gas is evolved (equ. 2), and under no circumstances yet observed is the quantity of hydrogen evolved exactly equivalent to the sodium dissolved, as required by the first equation. Probably, therefore, the two reactions generally take place together (see, further, ACETO-ACETIC ACID).—12. With *iodine* and *aluminium foil* ethyl acetate yields ethyl iodide and aluminium acetate, $6EtOAc + Al_2 + 3I_2 = 6EtI + Al_2(OAc)_6$, and a similar reaction takes place with all the alkyl acetates of the series $C_nH_{2n+1}OAc$ (Gladstone a. Tribe, *C. J.* 30, 357).—13. Ethyl acetate combines with titanic chloride in various proportions (Demarçay, *Bl.* [2] 20, 127; *C. R.* 70, 1414).

CHLORINATED ETHYL ACETATES.—Chlorine is abundantly absorbed by ethyl acetate, and acts strongly upon it, even at ordinary temperatures, replacing two or more atoms of hydrogen; the action is accelerated by heat and by direct sunshine. Seven compounds have been described as thus formed, containing 2 to 8 at. chlorine in place of hydrogen, but only three of them have been obtained of constant composition, viz., those containing 2, 3, and 5 at. chlorine.

Dichlorethyl Acetate $C_4H_6Cl_2O_2$ *i.e.* $C_2H_3Cl_2.C_2H_3O_2$ is the product formed when ethyl acetate is kept cool and in the shade during the action of the chlorine. Transparent oil. S.G. 3·01 at 12° (Malaguti, *A. Ch.* [2] 70, 367).

Trichloro-ethyl-acetate $CHCl_2.CHCl.OAc$, metameric with *ethyl tri*-CHLORO-ACETATE (*q. v.*) is formed by the action of chlorine at 120°, in presence of iodine, on ethylidene aceto-chloride, $CH_3CHCl.OAc$ (Kessel, *B.* 10, 1999).

—$CCl_3.CH_2OAc$ (72°) at 18mm., (167°) at 736mm. S.G. $\frac{22}{3}$ 1·39. V.D. 6·89 (for 6·63). From trichloro-ethyl alcohol and AcCl at 130°. Rectified *in vacuo* (Garzarolli-Thurnlackh, *A.* 210, 63). Fuming HNO_3 converts it, at 15°, into tri-chloro-acetic acid. KOH forms tri-chloro-ethyl-glycollic acid, $CCl_3.CH_2.O.CH_2CO_2H$.

Octo-chlorinated Ethyl Acetate $C_4Cl_8O_2$ *i.e.* $C_2Cl_5.C_2Cl_3O_2$ is slowly formed on exposing the dichlorinated ether, together with chlorine, at 100° to bright summer sunshine. The product, after distillation in a stream of carbon dioxide to remove excess of chlorine, forms a colourless pungent oil which remains liquid below 0°. S.G. 1·79 at 25°. Boils, with partial decomposition, at 245°. Its vapour passed over fragments of glass heated to 400° is converted into the isomeric compound chloraldehyde $C_2Cl_4O = CCl_3.COCl$. It is decomposed by water and moist air, and more completely by KOH, into hydrochloric and trichloracetic acids:

$$C_2Cl_5.C_2Cl_3O_2 + 2H_2O = 2HCl + 2(CCl_3.CO_2H)$$

(Leblanc, *A. Ch.* [3] 10, 197; Malaguti, *ib.* 15, 258).

The following chlorinated acetic ethers are also known: the compound of ALDEHYDE with AcCl, GLYCOL chloro-acetin, and the ethyl salts of the three CHLORO-ACETIC ACIDS.

BROMINATED ETHYL ACETATES $C_4H_6Br_2O_2 = CH_2Br.CO.OCHBr.CH_3$ (bromethyl bromacetate), formed on heating ethylidene acetate-chloride CHMeCl(OAc) with bromine at 100°–103°, boils under reduced pressure at 130–135°, and dissolves in boiling water, with formation of aldehyde, acetic acid, crotonaldehyde, acetal, ethyl bromide, and HBr. The crotonaldehyde and acetal are secondary products formed from acetaldehyde, produced in the first instance as shown by the equations:

$$CH_2Br.CO.OCHBr.CH_3 + C_2H_5OH = CH_2Br.COOC_2H_5 + CH_3.CHBr(OH)$$

$$\text{and } CH_3.CHBr(OH) = HBr + CH_3.CHO.$$

Tri- and *Tetra-brominated Ethyl Acetates* $C_4H_5Br_3O_2$ and $C_4H_4Br_4O_2$, formed by the action of 1 or 2 mol. bromine at 120° and 160°, respectively, on $C_2H_6Br_2O_2$, and freed from absorbed HBr by heating in a stream of carbon dioxide, are oily strongly fuming liquids, partly decomposing on distillation; decomposed also by water and alcohol, the products containing substances which reduce ammoniacal silver solution, whence it appears that both these ethers produce aldehydes. The *pentabrominated* compound $C_4H_3Br_5O_2$, probably $CH_2Br.CO.OCBr_2.CHBr_2$, formed by heating $C_4H_4Br_4O_2$ with 1 mol. bromine at 170°, is a liquid which scarcely fumes in the air (176°). Its product of decomposition by water does not reduce ammoniacal silver solution. Heated with excess of bromine, it forms $C_4H_2Br_6O_2$ (195°–198°) (Kessel, *B.* 10, 1994; 11, 1917). Other brominated acetic ethers are $CH_3CHBr.OAc$ *v.* ALDEHYDE, $CH_2Br.CH_2.OAc$ *v.* GLYCOL, and the ethylic BROMO-ACETATES.

Ethyl Ortho-acetate $CH_3.C(OEt)_3$.—Triethylic acetate; (142°), S.G. ^{22} ·94, formed, together with $CH_2Cl.C(OEt)_3$, by heating $CH_3.CCl_3$ with NaOEt in a sealed tube at 110°. Fragrant liquid. Decomposed by water into alcohol and acetic acid (Geuther, *J.* 1870, 636).

The acetates of the higher alkyls, C_nH_{2n+1}, are analogous in their properties and reactions to ethyl acetate, and are obtained, in like manner, either by heating the corresponding alcohols with acetic and sulphuric acid, or by the action of silver acetate on the corresponding alkyl iodides. The following table shows their boiling points and their S.G. in the liquid state.

	B.P.	S.G.
Propyl Acetates C_3H_7OAc:		
Normal Propyl acetate $Me(CH_2)_2OAc$ or PrOAc	102°	0·913 at 0°
Isopropyl acetate $Me_2CH.OAc$ or PrOAc.	90°–93°	
Butyl Acetates C_4H_9OAc:		
Normal Primary: $Me(CH_2)_3OAc$ or CH_2PrOAc	124°	0·9016 "
Isoprimary: $Me_2CHCH_2.OAc$ or CH_2PrOAc	116·5°	0·8596 "
Secondary: Methyl ethyl carbyl acetate MeEtCH.OAc	111°	0·892 "
Tertiary: Trimethyl-carbyl acetate $CMe_3.OAc$	96°	
Amyl Acetates $C_5H_{11}OAc$:		
Normal Primary: $Me(CH_2)_4.OAc$	148·4°	0·8963 "
Isoprimary: $Me_2CH(CH_2)_2OAc$	137°	0·8837 "
Secondary: Diethyl-carbyl acetate $Et_2CH.OAc$	132°	0·9090 "
Methyl-isopropyl-carbyl acetate MePrCHOAc	125°	
Methyl-propyl-carbyl acetate MePrCHOAc	133°	0·9222 "
Tertiary: Dimethyl-ethyl-carbyl acetate $Me_2EtC.OAc$	125°	0·8909 "
Hexyl Acetates $C_6H_{13}OAc$:		
Normal Primary: $Me(CH_2)_5OAc$	169·5°	0·8890 at 17°
Secondary: Methyl-butyl-carbyl acetate $Me(CH_2)_3CHMe.OAc$	155°–157°	0·8778 at 0°
Methyl-tert-butyl-carbyl or Pinacolyl acetate $Me.CHOAc.CMe_3$	140°–143°	
Ethyl-propyl-carbyl acetate EtPrCHOAc	150°	
Heptyl Acetates:		
Normal from *n*-heptane	180°	
Do. from Œnanthol	192°	0·874 at 16°
Methyl-amyl-carbyl acetate $Me(C_5H_{11})CH.OAc$	170°

Ethyl-hexyl-carbyl acetate $Et(C_6H_{13})CHOAc$	211°	0·878 at 0°
Decyl Acetate:		
Normal $C_{10}H_{21}OAc$. Crystalline. (125°) at 15 mm.		
Dodecyl Acetate:		
Normal $C_{12}H_{25}OAc$. Solid. (151°) at 15 mm.		
Cetyl Acetate:		
$C_{16}H_{33}OAc$. Needles. [18·5°] (200°) at 15 mm.		
Octadecyl Acetate:		
$C_{18}H_{37}OAc$. [31°] (223°) at 15 mm.		
Iso-ceryl Acetate:		
$C_{27}H_{55}OAc$ [57°]		

Allyl Acetate *v.* Allyl acetate.

Phenyl Acetate *v.* Phenol.

Benzyl Acetate *v.* Benzyl acetate.

Methylene Di-acetate *v.* Formic aldehyde.

Ethylene Acetates *v.* Glycol.

Polyethylenic Acetates *v.* Glycol.

Ethylene Aceto-butyrate *v.* Glycol.

Ethylene Aceto-chloride *v.* Glycol.

Propylene Acetate *v.* Propylene-glycol.

Butylene Acetate *v.* Oxy-butanes.

Amylene Acetate *v.* Oxy-pentanes.

Glyceryl Acetates *v.* Glycerin.

Substitution products of Acetic Acid v. Bromo-acetic acids, Chloro-acetic acids, Iodo-acetic acids, Cyano-acetic acid, Sulpho-cyano-acetic acids, Sulpho-acetic acid.

Other derivatives of Acetic Acid v. Acetyl bromide, Bromo-acetyl bromide, Chloro-acetyl bromide, Cyano-acetyl bromide, Acetyl cyanide, Acetyl chloride, Acetyl iodide, Di-azo-acetic acid. H. W.

ACETIC BROMIDE *v.* Acetyl bromide.

ACETIC CHLORIDE *v.* Acetyl chloride.

ACETIC CYANIDE *v.* Acetyl cyanide.

ACETIC IODIDE *v.* Acetyl iodide.

ACETIC OXIDE or ANHYDRIDE $C_4H_6O_3$ or Ac_2O.—*Acetyl oxide, Acetic acid, Anhydrous acetic acid.*—M.w. 102. (137·8°) at 755 mm. (Kopp.); (44·6) at 15 mm., (136·4°) at 760 mm. (Kahlbaum). S.G. ^{0} 1·097, $^{15\cdot2}$ 1·799 (K.); $\frac{20}{4}$ 1·0816 (Brühl). V.D. 3·47 (for 3·51). μ_β 1·3953. R_∞ 35·82 (B.). H.F.p. 132,850. H.F.v. 130,820.

Formation.—1. By the action of phosphorus trichloride or oxychloride on potassium acetate, $3KOAc + POCl_3 = K_3PO_4 + 3AcCl$, and $AcCl + KOAc = KCl + Ac_2O$ (Gerhardt, 1853, *C. R.* 34, 755, 902; *A. Ch.* [3] 37, 285).—2. From potassium acetate and benzoyl chloride, the first product of the reaction being acetobenzoic oxide, which, if the potassium acetate is somewhat in excess, and the mixture is heated to a temperature somewhat above that required for its formation, is resolved into acetic and benzoic oxides: $KOAc + BzCl = KCl + AcOBz$; and $2AcOBz = Ac_2O + Bz_2O$. Similarly from potassium benzoate and acetyl chloride (Gerhardt).—3. By digesting glacial acetic acid and acetyl chloride in molecular proportions (Kanonnikoff a. Saytzeff, *A.* 185, 192).—4. From lead or silver acetate and carbon bisulphide

$$2Pb(OAc)_2 + CS_2 = 2PbS + 2Ac_2O + CO_2$$

(Broughton, *Z.* 1865, 306).—5. From acetal chloride and barium oxide at 100° (Gal).—6. In small quantity by the action of phosphoric anhydride on glacial acetic acid (Gal; Etard, *B.* 9, 444).—7. By the action of lead nitrate on acetyl chloride (Lachowicz, *B.* 17, 1281).

Preparation.—1. Acetyl chloride (1 pt.) is run into sodium acetate (1 pt.) or potassium acetate (1¼ pt.), and the product is distilled. As, however, acetyl chloride is formed by the action of the chlorine compounds of phosphorus on acetates, it is clear that, for the preparation of the anhydride, this chloride need not be quite free from phosphorus oxychloride. It is sufficient, indeed, to add $POCl_3$ (3 pts.) directly to an excess of NaOAc (10 pts.) or KOAc (12 pts.) and distil; or to prepare a mixture of $POCl_3$ and AcCl, by the action of PCl_5 (7 pts.) on glacial acetic acid (2 pts.), and distil this mixture with NaOAc (20 pts.) or KOAc (24 pts.). In all these modes of preparation it is necessary to heat the mixture strongly towards the end of the distillation, because a portion of the acetic oxide unites with the excess of metallic acetate present, forming a compound which requires a high temperature to decompose it. The acetic oxide thus obtained must be subjected to fractional distillation to free it from residual chlorides and acetic acid (Kekulé, *Lehrb.* 1, 570).—2. Hentschel (*B.* 17, 1285) prepares acetic anhydride by passing a stream of carbonyl chloride, $COCl_2$, into fused dry sodic acetate.

Properties.—Colourless, very mobile, strongly refracting liquid, having an odour like that of glacial acetic acid, but stronger.

Reactions.—1. With HCl-gas acetic oxide acts strongly at 100°, forming acetic acid and chloride: $Ac_2O + HCl = AcOH + AcCl$ (Gal, *A. Ch.* [3] 66, 187).—2. With *chlorine* at 100° the products are acetyl chloride and chloracetic acid:

$$(C_2H_3O)_2O + Cl_2 = C_2H_3OCl + C_2H_3ClO_2$$

(Gal). Similarly with Br. With *iodine* no action at 200°, but at higher temperatures HI is given off (Gal).—3. With PCl_5, it yields acetyl chloride: $Ac_2O + PCl_5 = POCl_3 + 2AcCl$.—4. Heated with solid *aluminium chloride* it forms acetyl chloride and aluminium acetate:

$$3Ac_2O + AlCl_3 = 3AcCl + Al(OAc)_3$$

(Andrianowsky, *J. R.* 11, 116).—5. With pulverised *zinc chloride* at 100° it yields acetic acid, acetic oxide, and a dark brown residue having the composition C_4H_2O (Bauer, *J.* 1861, 438).—6. By heating with *zinc-dust* it yields acetone (Jahn, *M.* 1, 696).—7. Reduced by *sodium amalgam* it forms aldehyde, and afterwards alcohol:

$$(CH_3CO)_2O + 2H_2 = 2CH_3CHO + H_2O;$$
$$2CH_3CHO + 2H_2 = 2CH_3CH_2OH$$

(Linnemann, *A.* 148, 249).—8. Heated in CO_2-gas at 60° with $Cl.SO_2.OH$, it forms an acid, $C_2H_6SO_7$ (Gal).—9. With *urea*, at the boiling-point, it forms acetyl carbamide, $NHAcCO.NH_2$. No reaction with *oxamide* (Scheitz; Marsh a. Geuther, *Bl.* [2] 10, 460).—10. With nascent *zinc-ethyl* (2 mol. EtI and 1 mol. Ac_2O added to zinc-sodium) it yields methyl-ethyl ketone:

$$(COMe)_2O + ZnEt_2 = ZnO + 2(Me.CO.Et).$$

With *zinc-methyl* in like manner: acetone, Me.CO.Me (Saytzeff, *Z.* [2] 6, 104).—11. Forms crystalline compounds with $NaHSO_3$ and with NH_3. The latter is formed by passing NH_3 into an ethereal solution of Ac_2O at −26° (Loir, *C. R.* 88, 812).—12. Gives a mirror with ammoniacal $AgNO_3$ (Loir).—13. Decolorises aqueous $KMnO_4$ (Loir).—14. Converted by H_2SO_4 at 130° into sulpho-acetic acid (Franchimont, *C. R.* 92, 1054).

Compounds.—A. With *potassic acetate* $Ac_2O2KOAc$, obtained by dissolving dry potassium acetate in Ac_2O at 100°, crystallises in needles, and is resolved into its constituents by heat (Gerhardt). B. With aldehydes.—(1.) With *acetaldehyde* acetic oxide forms the compounds $C_2H_4OAc_2O$ and $C_2H_4O2Ac_2O$. The first is obtained by heating its constituents together in molecular proportion at 180° in a sealed tube, and purified by fractional distillation, washing the portion which distils above 140° with hot water, and drying over $CaCl_2$. It is a liquid which boils at 168°, has an alliaceous odour, and is resolved by heating with KOH into acetic acid and aldehyde—distinction from the isomeric compound, ethylene acetate

$C_2H_4(OAc)_2$, which, when similarly treated, yields glycol, $C_2H_4(OH)_2$ (Geuther, *A.* 106, 249). The second compound, $C_2H_4O.2Ac_2O$, formed by heating paraldehyde with Ac_2O at 160°, is a liquid having a density of 1·07 at 10° (Geuther, *J.* 1864, 329). (2.) With *acrolein.*—The compound $C_3H_4OAc_2O$ is obtained by heating its components in molecular proportion at 100° for six hours, or 1 mol. acroleïn chloride with 2 mols. silver acetate at about 160°. Liquid immiscible with water, having a fishy odour and very sharp taste. S.G. 1·076 at 22°; (180°). $C_3H_4O2Ac_2O$, formed by heating metacroleïn with Ac_2O at 150°, is an oily liquid boiling at 180° (Hübner a. Geuther, *A.* 114, 35; *J.* 1860, 306). (3.) With *benzaldehyde.*—$C_7H_6OAc_2O$ is formed on heating bitter-almond oil with excess of Ac_2O at 150°, and separates on washing the product with water and potash as an oily liquid, which solidifies to a crystalline mass melting at 44°–45° (Hübner, *Z.* [2] 3, 277). These compounds may be looked upon as derived from *ortho-aldehydes*, $XCH(OH)_2$. Similar compounds will be described in articles on the several aldehydes. C. With other oxides.—Vapour of SO_3 is absorbed by cooled Ac_2O, forming a gummy mass soluble in water. *Boric oxide* dissolves slowly in Ac_2O, forming a vitreous hygroscopic mass. *Insoluble tartaric oxide* or *anhydride*, $C_4H_4O_5$, dissolves at 100° in acetic oxide, forming a syrup. The same syrupy product is formed, together with $PbCl_2$, by the action of AcCl on lead tartrate.

Aceto-arsenious Oxide $C_4H_6O_3As_2O_3$ or Ac.O.OAs is formed by dissolving As_2O_3 in acetic oxide at boiling heat, as a syrupy liquid, which on cooling forms a vitreous hygroscopic mass.

Aceto-hypochlorous Oxide AcOCl and *Aceto-hypoiodous Oxide* AcOI have been described as unstable compounds by Schützenberger (*C. R.* 52, 359; 54, 1026; *J.* 1862, 240), but their existence has been called in question by Aronheim (*B.* 12, 26).

Aceto-silicic Oxide $Si(OAc)_4$ [110°] (148°) at 6mm. From Ac_2O and SiO_2 (Friedel a. Ladenburg, *A.* 145, 174). Decomposed by water, heat, alcohol, or NH_3, into silica and $HOAcAc_2O$, EtOAc, and NH_2Ac, respectively. A compound, $Si(OEt)_3(OAc)$ (c. 195°), is formed from $Si(OEt)_4$ and Ac_2O.

Aceto-benzoic Oxide $C_9H_8O_3$ i.e. AcOBz, from acetyl chloride and sodium benzoate, is a heavy oil. Begins to boil at 150°, and is resolved at the same time into Ac_2O and Bz_2O. By boiling with water, and more quickly with alkalis, it is converted into acetic and benzoic acids (Gerh. 3, 209). HCl converts it at low temperatures into AcCl and HOBz; at 150° BzCl and HOAc are also formed. Chlorine forms AcCl and o-chloro-benzoic acid (Greene, *C. N.* 50, 61).

Aceto-cinnamic Oxide $Ac.O.C_9H_7O$. Obtained like the preceding, which it resembles. Oil, heavier than water, very unstable (Gerhardt, *ib.* 387).

Aceto-cuminic Oxide $Ac.O.C_{10}H_{11}O$. Like the preceding (Gerhardt, *ib.* 509).

Aceto-salicylic Oxide $Ac.O.C_7H_5O_2$. Solid; dissolves in aqueous sodium carbonate, with formation of sodium acetate and salicylate (Gerhardt, *ib.* 319).

Acetic Peroxide $C_4H_6O_4$ or Ac_2O_2.—Prepared by adding BaO_2 to a solution of acetic anhydride in ether. The mixture is effected gradually, being attended with evolution of heat. The ether is distilled off at a low temperature, and the fluid which remains is washed with water. It is a viscid liquid with pungent taste. It decolorises indigo, oxidises manganous hydrate to peroxide, and potassic ferro- to ferricyanide. It acts generally as an oxidising agent. It does not reduce CrO_3 or $KMnO_4$. Baryta-water is converted by it into barium peroxide and acetate. It explodes when heated (Brodie, *Pr.* 9, 363). H. W.

ACET-IMIDAMIDE *v.* ACETAMIDINE.

ACET-IMIDO-ETHYL-ETHER

$$CH_3.C\begin{matrix}\nearrow NH\\ \searrow OEt\end{matrix}$$

(97°). Liquid. The hydrochloride is obtained by passing dry HCl-gas into a mixture of acetonitrile and ethyl alcohol (equal mols.) diluted with $\frac{1}{3}$ their volume of ether, cooled to 0° C. B′HCl, long trimetric plates, decomposes at about 100° into ethyl chloride and acetamide (Pinner, *B.* 16, 1654).

ACETIMIDO-NAPHTHYL-AMIDE *v.* NAPHTHYL-ACETAMIDINE.

ACETIMIDO-TOLYL-AMIDE *v.* TOLYL-ACETAMIDINE.

ACETO-ACETIC ACID $CH_3.CO.CH_2.CO_2H$ or $CH_3.C(OH):CH.CO_2H$.

Occurrence.—In urine of diabetic patients (Geuther a. Rupstein, *Fr.* 14, 419; Deichmüller, *A.* 209, 30; Tollens, *A.* 209, 36; Jaksch, *H.* 7, 487).

Preparation.—The ethyl ether (4·5 g.) is mixed with water (80 g.) containing KOH (2·1 g.), and after 24 hours the liquid is acidified and shaken with ether (Ceresole, *B.* 15, 1327, 1872).

Properties.—A thick acid liquid, miscible with water. At 100° it splits up into CO_2 and acetone. Nitrous acid gas forms CO_2 and iso-nitroso-acetone.

Salts.—BaA'_2aq. Amorphous. V.e. sol. water. Violet colour with $FeCl_3$.—$CuA'_2$2aq. Amorphous.

Ethyl Aceto-acetate or *Aceto-acetic Ether* $CH_3.CO.CH_2.CO_2Et$ or $CH_3.C(OH):CH.CO_2Et$. *Di-acetic ether* (Geuther, *J.* 1863, 323), *ethyl-di-acetic acid* (Geuther, *J.* 1865, 302), *acetone-carboxylic acid* (Frankland a. Duppa, *A.* 138, 211) (180°) (R. Schiff, *B.* 19, 561); (180·8° cor.) (Geuther); (180·6°–181·2°) at 754 mm. (Brühl); (152·5°–153°) at 330 mm. (Perkin). S.G. $\frac{20}{4}$ 1·0256 (B.); $\frac{0}{4}$ 1·046 (S.); $\frac{15}{15}$ 1·0317 (P.); $\frac{25}{25}$ 1·0235 (P.). μ_β 1·4253. R_∞ 51·62 (B.). S.V. 153·34 (S.). M.M. 6·501 at 16·25 (P.).

Formation.—The formation of aceto-acetic ether by the saponification of cyano-acetone by alcoholic HCl (Matthews a. Hodgkinson, *B.* 15, 2679) is denied by James (*A.* 231, 245).

Preparation.—Ethyl acetate (1 kilo.), that has been carefully dried, is treated with sodium (100 g.) in small pieces. As soon as the first reaction abates it is heated with inverted condenser over a water bath for 2½ hours until the sodium is dissolved. Dilute (50 p. c.) acetic acid (550 g.) is then added, and when the liquid is cool, it is mixed with water (500 c.c.). The light oily layer is washed with a little water and fractioned. The yield (175 g.) is small, but much ethyl acetate (400 g.) is recovered (Conrad, *A.* 186, 214). Aceto-acetic ether may be still further purified by shaking with conc. aqueous $NaHSO_3$, with which it combines. Impurities may then be extracted by ether, and the compound of aceto-acetic ether with $NaHSO_3$ afterwards decomposed by K_2CO_3 (Elion, *R.* 3, 246).

The formation of aceto-acetic ether may be expressed by the equation:

$$2CH_3.CO_2Et + Na_2 = CH_3.CO.CHNa.CO_2Et + NaOEt + H_2,$$

the sodio-aceto-acetic ether being afterwards decomposed by the added acetic acid:

$$CH_3.CO.CHNa.CO_2Et + HOAc = CH_3.CO.CH_2.CO_2Et + NaOAc.$$

See also p. 21.

Properties.—A liquid with an agreeable sweet odour. Slightly soluble in water, the liquid giving a violet colour with $FeCl_3$. Unlike its ethyl and acetyl derivatives, it forms a crystalline compound with $NaHSO_3$ (indicating presence of the ketonic carbonyl group, CO).

Salts.—Aceto-acetic ether behaves as a monobasic acid. This may either be ascribed to the situation of the group CH_2 between two CO groups, or else by having recourse to the formula $CH_3.C(OH):CH.CO_2Et$, which represents a compound that might be expected, as a tertiary alcohol, to possess a phenolic character. Like phenol, it gives a violet colour with $FeCl_3$.

Sodio-aceto-acetic Ether $CH_3.CO.CHNa.CO_2Et$ or $CH_3.C(ONa):CH.CO_2Et$. Needles. Produced by the action of sodium or sodic ethylate upon aceto-acetic ether in the cold.

Preparation.—Sodium (10 g.) is dissolved in absolute alcohol (100 g.); when cold, dry ether (90 g.), followed by aceto-acetic ether (56·5 g.) diluted with ether (60 c.c.), is added. If the liquid is well stirred with a little water (2 c.c.) solid sodium acetacetic ether separates (Harrow, *C. J.* 33, 426). The pp. is a hydrate, which becomes dry in an exsiccator (Elion, *R.* 3, 240).

Reactions.—(*a*) With iodine in ethereal solution it gives di-aceto-succinic ether (*q. v.*).—(*b*) Heated alone or with NaOEt it gives acetone, aceto-acetic ether, NaOAc, and sodic dehydracetate.—(*c*) With *alkyl iodides* it forms alkyl-aceto-acetic ethers (*q. v.*):

$$CH_3.CO.CHNa.CO_2Et + R'I = NaI + CH_3.CO\,CHR'.CO_2Et.$$

Other iodo- bromo- and chloro- compounds act similarly.—(*d*) But with tri-PHENYL-METHYL BROMIDE Ph_3CBr it forms $CH_3CO.C(CPh_3)_2.CO_2Et$ (Allen a. Kölliker, *A.* 227, 110).—(*e*) Chloroform, in presence of NaOEt forms OXY-UVITIC ETHER: $C_6H_2Me(OH)(CO_2H)_2$ [1 : 3 : 4 : 6], the first stage probably being:

$$2CH_3.CO.CHNa.CO_2Et + NaOEt + CHCl_3 = CO_2Et.CHAc.CH:C(CO_2Et).CO.CH_3 + 3NaCl + HOEt$$

(Oppenheim a. Pfaff, *B.* 7, 929; 8, 884; 9, 321; Conrad a. Guthzeit, *A.* 222, 249).

Other Salts.—$Al(C_6H_9O_3)_3$. Needles [76°]. Insol. water, v. e. sol. ether, benzene or CS_2. May be sublimed.—$Co(C_6H_9O_3)_2$. Red pp. Sol. hot benzene or ether.—$Cu(C_6H_9O_3)_2$ [182°]. Green needles (from alcohol). Insol. water, v. sol. benzene, ether or CS_2. Got by adding $Cu(OAc)_2$ to a solution of aceto-acetic ether in alcohol, the calculated quantity of ammonia being also added (Conrad a. Guthzeit, *B.* 16, 19).—$Mg(C_6H_9O_3)_2$ [240°]. From aceto-acetic ether and 'magnesia-mixture.' Plates (from ether-benzene).—$Hg(C_6H_9O_3)_2$ Amorphous. Formed by shaking aceto-acetic ether with HgO.—$Ni(C_6H_9O_3)_2$.

Reactions.—1. Boiled for a long time, or passed through a red-hot tube, it forms dehydracetic acid, $C_8H_8O_4$, and alcohol.

2. Boiled with *alkalis* it gives CO_2, acetone, acetic acid and alcohol, according to the reactions:

$$CH_3.CO.CH_2.CO_2Et + 2KOH = CH_3.CO.CH_3 + K_2CO_3 + HOEt;$$
$$CH_3.CO.CH_2.CO_2Et + 2KOH = 2CH_3.CO.OK + HOEt.$$

3. Decomposed by water at 150°, or by strong acids, into CO_2 acetone and alcohol.

4. Action of *sodium alcoholates.*—(*a*) Heated with dry NaOEt, or with alcoholic NaOEt, ethyl acetate is got in small quantity (12 p.c. of the theoretical) (Wislicenus, *A.* 186, 193; Isbert, *A.* 234, 160).—(*b*) 50 g. heated with NaOEt (from 8·9 g. Na) and MeOH (75 g.) at 130° gives methyl acetate (7 g.) and ethyl acetate (1 g.). Similar results are obtained by using PrOH instead of MeOH (Isbert).—(*c*) At 130° with NaOPr and excess of MeOH gives methyl acetate and a little propyl acetate.—(*d*) Heated with alcohol at 180° it is not affected, but if a very little NaOEt be present it is completely decomposed, yielding EtOAc. Similar results are got by using PrOH and NaOPr. *Resacetic Acid* $C_{14}H_{22}O_5$ is found in all these cases as a resinous body, not volatile with steam. It forms brown amorphous salts, NaA′, KA′, and NH_4A', sol. water (Isbert, *A.* 234, 167).

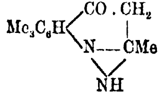
5. *Sodium-amalgam* forms β-oxy-butyric acid:

$$CH_3.CO.CH_2.CO_2Et + H_2 = CH_3.CH(OH).CH_2.CO_2Et.$$

6. *Phenyl-hydrazine* in the cold forms, as with all ketones, a phenyl-hydrazide:

$$\left.\begin{matrix}Ph.N\\ |\\ HN\end{matrix}\right\rangle CMe.CH_2.CO_2Et\ (?),$$

but at 100° this loses EtOH and becomes *methyl-oxy*-QUINIZINE (*q. v.*) (Knorr, *B.* 17, 2032). Pseudo-cumyl-hydrazine produces the homologous hydrazide $CH_3.C(N_2HC_6H_2Me_3).CH_2.CO_2Et$ [78°]. Long yellow needles (from alcohol), or thick prisms (from ether). V. sol. hot alcohol or ether, sl. sol. cold alcohol or benzoline. Very unstable, and at 130°–140° changes to oxy-tetra-methyl-quinizine:



(Haller, *B.* 18, 706).

7. *Hydroxylamine* forms, as with other ketones, the oxim: $CH_3.C(NOH).CH_2.CO_2Et$, β-Oximido-butyric acid, $CH_3.C(NOH).CH_2.CO_2H$; colourless crystals, [140°], sl. sol. water, alcohol or ether (Westenberger, *B.* 16, 2996).

8. Fuming *nitric acid* yields oxalic acid and OXIMIDO-ACETO-ACETIC ETHER (*q. v.*) (Pröpper, *A.* 222, 48).

9. *Sulphuryl Chloride* forms mono- or di-chloro-aceto-acetic ether, according to the proportions used (Allihn, *B.* 11, 567):

$$CH_3.CO.CH_2.CO_2Et + SO_2Cl_2 = CH_3.CO.CHCl.CO_2Et + SO_2 + HCl;$$
$$CH_3.CO.CH_2.CO_2Et + 2SO_2Cl_2 = CH_3.CO.CCl_2.CO_2Et + 2SO_2 + 2HCl.$$

10. *Bromine* gives *mono-*, *di-*, *tri-*, and *per* BROMO-ACETO-ACETIC ETHERS (Wedel. *A.* 219. [illegible]

11. *Chlorine* forms only *di*-CHLORO-ACETO-ACETIC ETHER (*q. v.*).

12. *Phosphorus pentachloride* forms the chlorides of two CHLORO-CROTONIC ACIDS (*q. v.*).

13. Dry *prussic acid* heated with aceto-acetic ether for 3 days at 100° forms a cyanhydrin, $CH_3.C(OH)(CN).CH_2.CO_2Et$, which is converted by boiling dilute HCl into oxy-pyrotartaric acid (G. H. Morris, *C. J.* 37, 7).

14. *Cyanogen chloride* passed into sodio-aceto-acetic ether forms CYANO-ACETO-ACETIC ETHER (*q. v.*) $CH_3.CO.CH(CN).CO_2Et$ (Haller a. Held, *C. R.* 95, 235).

15. *Ammonia*, whether dry (Precht, *B.* 11, 1193), aqueous or alcoholic (Duisberg, *A.* 212, 171), produces the imide of aceto-acetic ether.

Aceto-acetic ether imide $C_6H_{11}NO_2$ [34°]. (213° uncor.) at 760 mm., (154°) at 154 mm. S.G. [illegible] 1·014. S. (conc. NH_3Aq) 1·25. Dry NH_3 is greedily absorbed by aceto-acetic ether, the compound $CH_3.C(OH)(NH_2).CH_2.CO_2Et$ being doubtless at first formed. The liquid soon separates into two layers, water and the imide of aceto-acetic ether. The latter is purified by distillation (Collie, *A.* 226, 297). *Properties.*—Colourless monoclinic prisms. V. sl. sol. water, v. sol. alcohol, ether, benzene, CS_2 and $CHCl_3$. Moisture greatly lowers its melting-point. It is $CH_3.C(NH).CH_2.CO_2Et$ or $CH_3.C(NH_2):CH.CO_2Et$. *Reactions.*—(*a*) Aqueous HCl splits it up into NH_3 and aceto-acetic ether (Duisberg).—(*b*) Cold dilute NaOH has no action, but on warming it gives NH_3, HOEt, acetone and CO_2.—(*c*) $Pb(OAc)_2$, $HgCl_2$, $ZnSO_4$, or $FeCl_3$ also splits it into aceto-acetic ether and NH_3, the latter throwing down the metallic hydrate. $AgNO_3$ does not give any pp.—(*d*) Glacial acetic acid also regenerates aceto-acetic ether on boiling.—(*e*) Sodium amalgam gives *β*-oxy-butyric acid.—(*f*) Nitrous fumes passed into alcoholic solution forms nitroso-aceto-acetic ether. A by-product $C_8H_{17}N_5O_5$, forms plates [170°].—(*g*) Ac_2O at 160° forms an acetyl derivative, $C_6H_{10}AcNO_2$ [63°] (232°), which combines with bromine, forming $C_6H_{10}AcBr_2NO_2$ [140°].—(*h*) Paraldehyde gives di-hydro-tri-methyl-pyridine di-carboxylic acid, which is also formed from aceto-acetic ether, NH_3, and aldehyde.—(*i*) EtI at 100° forms ethyl-aceto-acetic ether and a base (c. 290°), possibly ethoxy-di-methyl-pyridine. *Condensation-products*: $C_{10}H_{13}NO_3$ [160°]. Present in the brown resin got when $C_6H_{11}NO_2$ is distilled under atmospheric pressure. Insoluble in alcohol and ether. Boiled with KOHAq it forms oxy-di-methyl-pyridine carboxylic acid.

16. *Aceto-acetic ether methyl-imide*,

$$CH_3.C(NMe):CH_2.CO_2Et \text{ or}$$
$$CH_3.C(NHMe):CH.CO_2Et,$$

(133°) at 50 mm., (215°) at 760 mm., is formed in like manner from aceto-acetic ether and *methylamine* (Kuchert, *B.* 18, 618). With paraldehyde and H_2SO_4 it gives a condensation-product, $C_{13}H_{22}O_4N$, which forms trimetric crystals with blue fluorescence [86°].

17. *Diethylamine* forms *β-di-ethyl-amido-crotonic ether*, $CH_3.C(NEt_2):CH.CO_2Et$, a liquid (160°–163°) at 20 mm.

18. Heated with *aniline* (1 mol.) at 120° it yields a crystalline body, $C_{10}H_{11}NO_2$, which melts at 81° and is probably the anilide of acet-acetic acid $CH_3.C(NPh).CH_2.CO_2H$. By dissolving this substance in cold H_2SO_4, H_2O is eliminated with formation of (Py. 1)-oxy-(Py. 3)-methyl-QUINOLINE (Knorr, B. 16, 2593).

19. *o-Phenylene-diamine* forms:

$$C_6H_4(N:CMe.CH_2.CO_2Et)_2.$$

20. *o-Tolylene-diamine* gives:

$$CH_3.C_6H_3\langle{}^{NH}_{NH}\rangle CMe.CH_2.CO_2Et.$$

(Ladenburg, *B.* 12, 951; Witt, *B.* 19, 2977).

21. With *aldehydes* (Claisen, *B.* 12, 345):

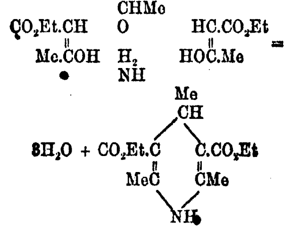
$$CH_3CO.CH_2.CO_2Et + RCOH =$$
$$H_2O + CH_3.CO.C(CH.R).CO_2Et.$$

The bodies are mixed in molecular proportions, and HCl is passed in at 0°. Or the bodies may be heated with Ac_2O. Examples (Matthews, *C. J.* 43, 200):—(*a*) *Isobutyric aldehyde* gives $C_{10}H_{16}O_3$ (219°–222°). Oil. Smells like peppermint. Combines with bromine. (*b*) *Valeric aldehyde* gives $C_{11}H_{18}O_3$ (237°–241°). S.G. $\frac{15}{15}$ ·9612. Oil. Smells of strawberries. (*c*) *Chloral* gives $C_4H_9Cl_3O_3$ (154°–158°) at 25 mm. S.G. $\frac{15}{15}$ 1·3420. From chloral, acet-acetic ether, and Ac_2O at 150°. (*d*) *Furfural* gives $C_{11}H_{12}O_4$ [62°], (188°–189°) at 30 mm. From furfural, acet-acetic ether, and Ac_2O. Easily soluble in chloroform, acetic acid, alcohol, and benzene. Large doubly-refracting crystals (from light petroleum and ether).

22. Aceto-acetic ether (2 mols.) condenses with *aldehyde-ammonia*, forming di-hydro-tri-METHYL-PYRIDINE-DI-CARBOXYLIC ETHER (*q. v.*):

$$2CH_3.CO.CH_2.CO_2Et + CH_3.CH(OH)NH_2 =$$
$$3H_2O + C_5H_2NMe_3(CO_2Et)_2.$$

Since the product contains three methyls and two CO_2Et groups, we may assume these to be identical with the same groups in the reacting bodies. And inasmuch as the product is not acted upon by nitrous acid gas and forms an ammonium iodide with MeI, it would seem to be a tertiary base. Nevertheless, inasmuch as methylamine and aldehyde give a similar body, the reaction may probably be represented thus:



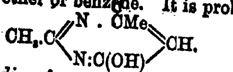
(Hantsch, *A.* 215, 74; *B.* 18, 2579). Other aldehydes in presence of NH_3 form similar derivatives of the pyridine series (*v.* METHYL-PYRIDINE). Thus *cinnamic aldehyde* and ammonia forms di-methyl-styryl-di-hydro-pyridine di-carboxylic ether, $H_2C_5NMe_2(CH:CHPh)(CO_2Et)_2$, [148°] (Epstein, *A.* 231, 3).

23. With *formamide* and $ZnCl_2$ aceto-acetic ether gives di-methyl-pyridine carboxylic ether (Canzeroni a. Spica, *G.* 14, 449).

24. With *acetamide* and $AlCl_3$ it forms $CH_3.C(NAc).CH_2.CO_2Et$ [65°]. Needles. Converted by KOH into the amide of aceto-acetic ether.

25. Mixing with *acetamidine hydrochloride* and dilute NaOH, and, after standing for some days, evaporating to dryness and extracting with alcohol, yields a di-methyl-oxy-pyrimidine,

$C_6H_8N_2O$ [190°]. Needles. V. sol. water or alcohol, sl. sol. ether or benzene. It is probably



Propionamidine forms a homologue, methyl-ethyl-oxy-pyrimidine [130°]. Its hydrochloride forms thick prisms, $C_7H_{10}N_2OHCl$ [c. 243°]. V. e. sol. water, v. sol. alcohol—$(C_7H_{10}N_2OHCl)_2PtCl_4$ [236°]. Prisms. (Pinner, *B.* 17, 2520; 18, 2847).

26. With *urea* in alcoholic solution it forms β-uramido-crotonic ether (Behrend, *A.* 229, 5):

$$MeC(OH):CH.CO_2Et + NH_2.CO.NH_2 = NH_2.CO.NH.CMe:CH.CO_2Et + H_2O.$$

The free β-URAMIDO-CROTONIC ACID, when liberated from its salts, changes at once into its anhydride, methyl-uracil:

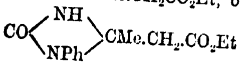
$$NH.CO.NH.CMe:CH.CO$$

27. *Thio-urea* (40 g.), heated with aceto-acetic ether (40 g.) slowly to 150°, gives a compound $C_5H_6N_2OS$ (5 g.), which may be *thio-methyl-uracil*. It may be crystallised from water. It dissolves in alkalis and is reppd. by acids. Its melting-point lies above 300°. Its aqueous solution gives with $AgNO_3$ an amorphous pp. of $C_5H_4Ag_2N_2SO$ (Nencki a. Sieber, *J. pr.* [2] 25, 72). If a little HCl be added to an alcoholic solution of thio-urea and aceto-acetic ether, unstable needles are formed. These are converted by alcoholic potash into potassium thio-methyl-uracil, $C_5H_5KN_2SO$ (List, *B.* 19, 219).

28. Aceto-acetic ether (20 g.), *phenyl-urea* (10 g.), and ether (6 g.) at 150° react thus:

$$C_6H_{10}O_3 + C_7H_8N_2O = C_{13}H_{16}N_2O_3 + H_2O.$$

The product is an oil which is decomposed by alcoholic potash with formation of ammonia and aniline, and by boiling conc. HCl with formation of CO_2, alcohol, acetone, and phenyl-carbamic ether, $PhNH.CO_2Et$. The reactions indicate that the body $C_{13}H_{16}N_2O_3$ has the constitution $NPhH.CO.N:CMe.CH_2CO_2Et$, or perhaps



(Behrend, *A.* 233, 1).

29. Combines directly with *di-phenyl-urea*, in presence of a little ether at 150°, forming an oil, $C_{19}H_{22}N_2O_4$. This body is converted by alcoholic KOH into aniline and K_2CO_3, and by acids into phenyl-carbamic ether and aniline. The body must be

$$PhNH.CO.NPh.C(OH)Me.CH_2.CO_2Et.$$

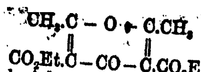
Similar addition products are probably first formed in the case of other ureas, but H_2O splits off:

$$PhNH.CO.NH.C(OH)Me.CH_2.CO_2Et = H_2O + PhNH.CO.N:CMe.CH_2.CO_2Et.$$

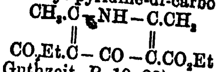
30. *p-Di-azo-toluene Chloride*, acting on an alcoholic solution of aceto-acetic ether, forms yellow needles of *p*-toluene-azo-aceto-acetic ether [188°] $C_6H_4Me.N_2.CH(CO.CH_3).CO_2Et$ (Richter a. Münzer, *B.* 17, 1929; *v.* AZO compounds).

31. *Hydrazo-benzene* at 100°–150° forms HOEt and a crystalline base, $C_{16}H_{14}N_2O$ (A. Müller, *B.* 19, 1771).

32. Copper aceto-acetic ether is converted by $COCl_2$ into an anhydride of di-acetyl-acetone di-carboxylic ether, $CO(CHAc.CO_2Et)_2$. The anhydride may be:



[80°]. Sol. glacial HOAc, H_2SO_4, conc. HCl, benzene, alcohol, or ether. NH_3 converts this body into oxy-di-methyl-pyridine-di-carboxylic ether



(Conrad a. Guthzeit, *B.* 19, 22).

33. Aceto-acetic ether, heated with CS_2 and PbO at 100°, forms 'thio-carbonyl-aceto-acetic ether' $CH_3.CO.C(CS).CO_2Et$ [156°–162°]. Yellow needles (from alcohol) (Norton a. Oppenheim, *B.* 10, 703).

34. S_2Cl_2 converts sodium aceto-acetic ether suspended in benzene into sulphido-aceto-acetic ether $S(CHAc.CO_2Et)_2$ [81°] (Buchka, *B.* 18, 2092).

35. With *succinic acid* it reacts thus:

$$C_6H_{10}O_3 + C_4H_6O_4 = C_{10}H_{12}O_5 + 2H_2O.$$

The product is a crystalline acid [76°], which is the acid ether of a dibasic acid $C_8H_8O_5$ [200°] (Fittig, *B.* 18, 2526).

Condensation products from aceto-acetic ether.—1. By *heat*: Passed through a red-hot tube it forms DEHYDRO-ACETIC ACID (*q. v.*) and other products (Perkins, jun. *C. J.* 47, 240).—2. By *hydrochloric acid*: Dry HCl at 8° forms, in four weeks, acetic ether and 'carb-aceto-acetic ether' $C_8H_{10}O_3$ (290°–295° uncor.). S.G. $\frac{27}{}$ 1·136. This liquid is slightly decomposed on distillation. It gives no colour with aqueous Fe_2Cl_6 (Duisberg, *A.* 213, 179). Carb-aceto-acetic ether is also formed when aceto-acetic ether is heated with acetyl chloride at 120° (Wedel, *A.* 219, 116).—3. By *sulphuric acid*:

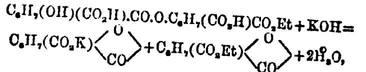
$$C_6H_7(OH)(CO_2H).CO.O.C_6H_7(CO_2H)(CO_2Et)$$

[62°]. Got by leaving a mixture of aceto-acetic ether (1 pt.) and cold conc. H_2SO_4 ($2\frac{1}{2}$ pts.) for fourteen days and then pouring into water (Hantzsch, *A.* 222, 4). Needles resembling asbestos. Sl. sol. cold water, m. sol. hot water and ether, v. sol. alcohol, v. e. sol. chloroform. Decomposed by heat. It is acid to litmus and, when hot, has a spicy odour. Its formation may be represented thus:

$$4C_6H_{10}O_3 = C_{18}H_{22}O_9 + 3C_2H_5OH.$$

Reactions.—(*a*) Boiling alkalis form carbonate and acetate, acetone, and mesityl oxide. (*b*) On neutralising with alcoholic potash it decomposes thus:

$$C_6H_7(OH)(CO_2H).CO.O.C_6H_7(CO_2H)CO_2Et + KOH =$$



the potassium salt of mesitene-lactone carboxylic acid being ppd. while its ether remains in solution.

Mesitene-lactone Carboxylic Acid

$$CH_3.C:C(CO_2H).CMe:CH.CO.O$$

[155°] (iso-dehydracetic acid). Fluffy crystals (from water). Sl. sol. cold water, v. sol. hot water. Monoclinic prisms (from alcohol). May be sublimed.

Reactions.—Distilled with lime it gives mesityl oxide.

Salts.—$KA'\frac{1}{2}aq.$ — NaA'. — NH_4A' — BaA'_2. — MgA'_2. — $CuA'_2 2aq.$ — $Ag_4H_2A'_3$. — $Ag_5HA'_3$. Strong bases convert iso-dehydracetic acid into oxy-mesitene dicarboxylic acid,

$$\mathrm{CH_3.C(OH)C:C(CO_2H).CMe:CH.CO_2H},$$

which forms a stable copper salt $\mathrm{Cu_3H_2A''_8}$, but its alkaline salts readily split off $\mathrm{CO_2}$:

$$\mathrm{C_6H_7(OH)(CO_2Na)_2 + NaOH = C_6H_8(OH)(CO_2Na) + Na_2CO_3},$$

forming oxy-mesitene carboxylates. These readily undergo a similar decomposition:

$$\mathrm{C_6H_8(OH)(CO_2Na) + NaOH = Na_2CO_3 + C_6H_9OH},$$

probably forming 'mesitenyl' alcohol, which at once changes to mesityl oxide. Baryta is the best alkali to use in these decompositions.

Mesitene Lactone

$$\mathrm{CH_3.\underline{C:CH.CMe:CH.CO.O}}$$

[51·5°] (245° cor.). From iso-dehydracetic acid by distillation, or by heating with $\mathrm{H_2SO_4}$ at 170°. Glittering tables. Very soluble in alcohol, ether, or water, sparingly so in $\mathrm{CS_2}$. Tastes bitter and spicy. Neutral to litmus. Separated by $\mathrm{K_2CO_3}$ from aqueous solution. Gives with Br in $\mathrm{CS_2}$ a bromo-derivative, $\mathrm{C_6H_7BrCO_2}$ [105°]. Converted even by water into oxy-mesitene carboxylic acid. Hence it is a δ-lactone.

Oxy-mesitene Carboxylic Acid

$$\mathrm{C_6H_8(OH)(CO_2H)}\ \textit{i.e.}\ \mathrm{CH_3.C(OH):CH.CMe:CH.CO_2H}.$$

From its lactone (mesitene-lactone) by boiling with water or, better, with baryta. A thick liquid, soluble in water. Its salts are amorphous, *e.g.* $\mathrm{BaA'_2}$, $\mathrm{CaA'_2}$. These salts on boiling form carbonate and mesityl oxide.

Mesitene-lactone Carboxylate of Ethyl

$$\mathrm{C_6H_7(CO_2Et)CO_2}\ \textit{i.e.}\ \mathrm{CH_3.\underline{C:C(CO_2Et).CMe:CH.CO.O}}.$$

Formed, together with its potassium salt, by the action of alcoholic KOH on the product of condensation of aceto-acetic ether, as described above. Also from its potassium salt by EtI. Also got when aceto-acetic ether, saturated with HCl, is left at 0° for a month (Polonowska, *B.* 19, 2402). Oil. *Reactions.*—(*a*) Br in $\mathrm{CS_2}$ forms $\mathrm{C_6H_6Br(CO_2Et)CO_2}$ [87°]. Needles (from alcohol).—(*b*) $\mathrm{NH_3}$ passed into an alcoholic solution forms satiny plates of $\mathrm{C_6H_7(CO_2Et)(CO_2NH_4)(ONH_4)}$ melting at [104°], giving off $\mathrm{2NH_3 + H_2O}$, and changing to the lactone. Warm water or cold alcohol also change it to the lactone. Cold HClAq liberates $\mathrm{C_6H_7(CO_2Et)(CO_2H)(OH)}$, which may be extracted by ether. Small plates [76°]. Boiled with water, two-thirds are changed to lactone, and when the lactone is boiled with water, one-third becomes oxy-acid. It forms salts of the form $\mathrm{C_6H_7(OH)(CO_2Et)(CO_2H)}$, viz. $\mathrm{CuA'_2aq}$, $\mathrm{PbA'_2aq}$. When the acid is boiled with alkali there is formed dehydracetic acid and its decomposition products, mesityl oxide, acetone, and $\mathrm{CO_2}$, and the following decomposition also occurs:

$$\mathrm{CH_3.\underline{C:C(CO_2Et).CMe:CH.CO.O} + 3H_2O = CH_3.CO_2H + HOEt + CH_2(CO_2H).CMe:CH.CO_2H},$$

resulting in homomesaconic acid.

Homomesaconic Acid

$$\mathrm{CH_2(CO_2H).CMe:CH.CO_2H}$$

[147°]. Small prisms (from water). V. sol. cold water, and alcohol, sl. sol. ether. Not volatile with steam, but sublimes about 120°.

Salts.—$\mathrm{BaA''4\frac{1}{2}aq}$.—$\mathrm{CaA''aq}$.—$\mathrm{CuA''2aq}$.—$\mathrm{Ag_2A''}$.—$\mathrm{KHA''}$.—$\mathrm{NH_4HA''}$.

Ethyl ether $\mathrm{Et_2A''}$. (240°–242°).

Theory of the Condensation.—As acetone gives mesityl oxide $\mathrm{C_6H_{10}O}$ or $\mathrm{CH_3.CO.CH:C(CH_3)_2}$, so aceto-acetic ether, if it is $\mathrm{CH_3.CO.CH_2CO_2Et}$, should give the dicarboxylic ether of mesityl oxide, $\mathrm{C_6H_8O(CO_2Et)_2}$, or the acid, $\mathrm{C_6H_8O(CO_2H)_2}$. Instead of this, it gives an isomeride of the latter, $\mathrm{C_6H_7(OH)(CO_2H)_2}$, so that the group CO.CH must have changed to C(OH):C. Assuming that this group pre-exists in aceto-acetic ether, the condensation would be as follows:

$$\mathrm{CH_3.C(OH):C(CO_2Et)H + HO.CMe:CH.CO_2Et = CH_3.C(OH):C(CO_2Et).CMe:CH.CO_2Et + H_2O = CH_3.\underline{C:C(CO_2Et).CMe:CH.CO.O} + HOEt + H_2O}.$$

Acetyl-aceto-acetic Ether

$\mathrm{CH_3.CO.CHAc.CO_2Et}$ or $\mathrm{CH_3.C(OAc):CH.CO_2Et}$, *di-aceto-acetic ether*. (200°–205°). S.G. $\frac{15}{15}$ 1·064 (James); $\frac{15}{15}$ 1·101 (Elion). From aceto-acetic ether (65 g.), ether (50 g.) and sodium (9 g.), by adding a solution of AcCl (30 g.) in ether (50 g.) in the cold (J. W. James, *A.* 226, 210; *C. J.* 47, 1).

Properties.—Pleasant smelling liquid, slightly decomposed on distillation. Miscible with alcohol, ether, and benzene, hardly soluble in water, but slowly decomposed by it into acetic acid and aceto-acetic ether. $\mathrm{Fe_2Cl_6}$ gives a raspberry-red colour, removed by $\mathrm{SO_2}$.

Salts.—Acetyl-aceto-acetic acid is a strong acid, and can expel acetic acid from its salts.—$\mathrm{CuA'_22aq}$: insoluble in water; [148°].—NaA' (Elion, *R.* 3, 255).—$\mathrm{NiA'_22aq}$.

Reactions.—1. NaOEt decomposes it into EtOAc and sodium aceto-acetic ether.

Benzoyl-aceto-acetic Ether

$$\mathrm{CH_3.CO.CBzH.CO_2Et}$$

From sodium aceto-acetic ether and benzoyl chloride alone (Bonné, *A.* 187, 1), or dissolved in ether (James, *A.* 226, 220; *C. J.* 47, 10).

Properties.—A fairly strong acid, capable of displacing acetic acid.

Salt.—$\mathrm{CuA'_2}$ (from benzene) [180°–190°]. Formed by shaking the ether with aqueous cupric acetate. Sl. sol. alcohol or benzene, m. sol. ether.

o-**Nitro-benzoyl-aceto-acetic Ether.**—Prepared as above, using nitro-benzoyl chloride. It is an oil. Boiled with dilute $\mathrm{H_2SO_4}$ it forms *o*-nitro-phenyl methyl ketone and also *o*-nitro-benzoyl-acetone in smaller quantity. Conc. KOH forms a salt $\mathrm{CH_3CO.C(C_6H_4NO_2)K.CO_2Et}$ (Gevekoht, *A.* 221, 323).

Constitution of Aceto-acetic Ether.

Some chemists adopt Frankland's formula for aceto-acetic ether, $\mathrm{CH_3CO.CH_2.CO_2Et}$; others prefer Geuther's formula, $\mathrm{CH_3.C(OH):CH.CO_2Et}$; while a third party, relying upon the results of Baeyer's researches into the constitution of the derivatives of indigo, consider that both formulæ are equally correct, or rather that at the moment of reaction the first may change into the second. Against Frankland's formula it is argued

(1) That the copper salt is blue or green, whereas compounds in which copper is united to carbon (*e.g.* copper acetylide) are red or yellow.

(2) That it does not account for the existence of acetyl and benzoyl derivatives.

(3) The formation of hydro-quinone dicarboxylic ether, a body containing two *hydroxyls*, by the action of sodium on di-bromo-aceto-acetic

derivative $C_6H_5.CO.C_6H_4NHBz$ [170°] (Higgin, *C. J.* 41, 133). Dilute HCl at 120° liberates the free bases, which are described as AMIDO-BENZOPHENONES (*q. v.*).

***p*-BENZOYL-PHENYL-CARBAMIC ETHER** $C_6H_5.CO.C_6H_4.NH.CO_2Et$ [189°]. Prepared by the action of chloroformic ether on *p*-amidobenzophenone (Doebner a. Weiss, *B.* 14, 1839; *A.* 210, 246). Plates. Sol. boiling alcohol, boiling acetic acid, and chloroform, insol. cold water. Decomposed by boiling KOH.

BENZOYL-PHENYL-CARBAMINE $C_6H_5.CO.C_6H_4.NC$. *Iso-cyano-benzophenone* [119°]. From *p*-amido-benzophenone (10 g.), chloroform (8 g.), and alcoholic KOH (Doebner, *A.* 210, 246). Silky needles, volatile with steam. Sl. sol. hot water, v. sol. alcohol. Split up by acids into formic acid and amido-acetophenone.

BENZOYL-PHENYLENE-DIAMINE *v.* PHENYLENE-DIAMINE.

BENZOYL-PHENYL-DI-ETHYL-AMINE *v.* DI-ETHYL-AMIDO-BENZOPHENONE.

BENZOYL-PHENYL-DI-METHYL-AMINE *v.* DIMETHYL-AMIDO-BENZOPHENONE.

***p*-DI-BENZOYL-DI-PHENYL-THIO-UREA** $SC(NH.C_6H_4.CO.C_6H_5)_2$. [166°]. Prepared by the action of CS_2 on an alcoholic solution of *p*-amido-benzophenone in presence of a little KOH (Doebner a. Weiss, *B.* 14, 1839). Colourless plates. Sol. chloroform, sl. sol. hot alcohol, ether, benzene and CS_2; insol. water.

BENZOYL-PHENYL-METHANE is BENZOYL-PHENYL-CARBAMIC ETHER (*q. v.*).

BENZOYL-PIPER-PROPYL-ALKEÏN *v.* *Benzoyl*-OXYPROPYL-PIPERIDINE.

BENZOYL-PROPANE-CARBOXYLIC ACID *v.* PHENYL PROPYL KETONE CARBOXYLIC ACID.

α-BENZOYL-PROPIONIC ACID $C_{10}H_{10}O_3$ *i.e.* $C_6H_5.CO.CHMe.CO_2H$. *Phenyl ethyl ketone α-carboxylic acid.* From the ether and conc. H_2SO_4, the mixture being left for 3 weeks. It is an oil and gives a reddish-brown colour with Fe_2Cl_6. Alkalis produce phenyl ethyl ketone.

Ethyl ether $CH_3.CHBz.CO_2Et$. (227°) at 225 mm. Formed by the action of NaOEt and MeI on benzoyl-acetic ether (*q. v.*). Aromatic smelling oil. Fe_2Cl_6 gives no colour in its alcoholic solution. NaOEt forms the sodium derivative $CH_3.CNaBz.CO_2Et$. Phosphorus pentachloride forms $C_6H_5.CCl{:}CMe.CO_2Et$ (Perkin a. Calman, *C. J.* 49, 156).

β-benzoyl-propionic acid $C_6H_5.CO.CH_2.CH_2.CO_2H$. *Phenyl ethyl ketone ω-carboxylic acid.* [116°]; [114°] (Bischoff, *B.* 19, 95).

Formation.—1. By the reduction of benzoyl-acrylic acid.—2. By the action of Al_2Cl_6 ($1\frac{1}{2}$ pts.) on a mixture of succinic anhydride (1 pt.) and benzene (10 pts.). The product is shaken with water, when the acid remains dissolved in the benzene, whence it is extracted by shaking with KOH and ppg. with HCl (Burcker, *Bl.* [2] 35, 17; *A. Ch.* [5] 26, 433; Pechmann, *B.* 15, 889). 3. By oxidising its aldehyde.—4. Its chloride is formed by the action of Al_2Cl_6 upon a mixture of succinyl chloride (1 mol.) and benzene (1 mol.) (Claus, *B.* 20, 1375).—5. By heating benzoyl-isosuccinic acid above its melting-point, CO_2 being evolved (Kues a. Paal, *B.* 18, 3325).

Properties.—White prisms, v. sol. hot water. Converted by potash-fusion into benzoic and propionic acids. Reduced by sodium amalgam to γ-oxy-phenyl-butyric acid (or its lactone). $C_6H_5.CH(OH).CH_2.CH_2.CO_2H$.

Salts.—BaA'_2: needles. — AgA': sl. sol. water.

Ethyl ether. EtA'. [32°]: white crystals, turned red by heat.

Phenyl-hydrazide $C_6H_5.C(N_2HPh).CH_2.CH_2.CO_2H$. [65°]. White silky needles, v. sol. alkalis, acids, alcohol, and benzene, sl. sol. ether.

BENZOYL-PROPIONIC ALDEHYDE $C_6H_5.CO.CH_2.CH_2.CHO$. (245°). S.G. $\frac{0}{0}$ 1·005; $\frac{15}{15}$ ·998. Prepared by the action of water upon the compound of phenyl propyl ketone with CrO_2Cl_2. Oil, sol. ether and chloroform. It readily reduces $AgNO_3$, but does not combine with $NaHSO_3$. Sodium-amalgam reduces it to syrupy $C_6H_5.CH(OH).CH_2.CH_2.CH_2OH$ (c. 200°) (Burcker, *A. Ch.* [5] 26, 469; *C. R.* 94, 220).

BENZOYL-PROPIONIC-CARBOXYLIC ACID *v.* PHENYL ETHYL KETONE DI-CARBOXYLIC ACID.

BENZOYL-PYROCATECHIN *v.* DI-OXY-BENZOPHENONE.

BENZOYL PYRROL *v.* PYRROL.

Pseudo-**benzoyl-pyrrol** *v.* PYRRYL PHENYL KETONE.

BENZOYL PYRUVIC ACID $C_{10}H_8O_4$ *i.e.* $C_6H_5.CO.CH_2.CO.CO_2H$. [156°]. Obtained by saponification of the ethyl ether. Yellowish-white prisms (from hot benzene). Strong acid. Evolves CO_2 at its melting-point.

Ethyl ether A'Et: [43°]. Prepared by adding 48 pts. of acetophenone to a cooled solution of 9·2 pts. of sodium in 150 pts. alcohol, and then 58·4 pts. of oxalic ether. The precipitated sodium compound is washed with ether, dried, dissolved in iced water, and decomposed by CO_2, when the benzoyl-pyruvic ether crystallises out; the yield is 78 p.c. of the theoretical. It crystallises from petroleum-ether in long prisms. V. sol. all ordinary solvents. Fe_2Cl_6 gives a blood-red colouration. The aqueous alcoholic solution gives with cupric acetate a light-green pp. of $(C_{12}H_{11}O_4)_2Cu$, this crystallises from hot benzene or alcohol in long green needles. By heating with dilute aqueous NaOH the ether is split up into acetophenone, oxalic acid, and alcohol. By boiling its acetic acid solution with phenyl-hydrazine it is converted into di-phenyl-pyrazol-carboxylic ether $C_3HPhN(NPh).CO_2Et$. By cold alcoholic NH_3 it is converted into acetophenone, oxamide, and alcohol (Beyer a. Claisen, *B.* 20, 2181).

BENZOYL-QUINALDINE *v.* METHYL-QUINOLYL PHENYL KETONE.

BENZOYL-RESORCIN *v.* DI-OXY-BENZOPHENONE.

Di-benzoyl-resorcin *v.* DIOXY-PHENYLENE DI-PHENYL DIKETONE.

BENZOYL-SUCCINIC ACID. *Phenyl ethyl ketone di-carboxylic acid.* *Ethyl ether* $CO_2Et.CHBz.CH_2.CO_2Et$. (c. 265°) at 160 mm. From sodium-benzoyl-acetic ether and chloro-acetic ether (Perkin, jun., *C. J.* 47, 274).

Properties.—Thick colourless oil. Its alcoholic solution gives a claret colour with Fe_2Cl_6. Conc. H_2SO_4 forms a yellow solution turned red by heat. NaOEt forms a solid sodium compound. Boiling baryta water decomposes it into benzoate and succinic acids. Boiling dilute H_2SO_4 forms benzoyl-propionic acid.

Di-benzoyl-succinic acid $CO_2H.CHBz.CHBz.CO_2H$. Obtained by dissolving the ether in alcoholic KOH and treating with H_2SO_4 (Perkin, jun., *C. J.* 47, 265). The acid dissolved in alcohol gives a dark-green pp. with Fe_2Cl_6. Conc. H_2SO_4 forms a yellow solution, turned crimson by heat.

Ethyl ether $CO_2Et.CHBz.CHBz.CO_2Et$. [130°]. Formed by adding iodine to a solution of sodium benzoyl-acetic ether in dry ether (Perkin, jun., *C. J.* 47, 262). Crystals (from alcohol); sl. sol. cold alcohol, v. sol. ether. Conc. H_2SO_4 forms a colourless solution turned red, olive-green, and finally bluish-red by heat. Sodium ethylate forms $CO_2Et.CNaBz.CNaBz.CO_2Et$. In the alcoholic solution Fe_2Cl_6 gives a red colour. Boiling dilute sulphuric acid (1:2) forms an acid probably diphenyl-furfurane dicarboxylic acid, $C_{18}H_{12}O_5$, [238°], whence Ac_2O forms an anhydride $C_{18}H_{10}O_4$, [255°] (Baeyer a. Perkin, *B.* 17, 62).

β-Benzoyl-isosuccinic acid *v.* PHENYL ETHYL KETONE ω-DI-CARBOXYLIC ACID.

BENZOYL SULPHIDE $(C_6H_5CO)_2S$. [48°]. From BzCl and potassium thiobenzoate (Engelhardt, Latschinoff, a. Malyscheff, *Z.* 1868, 357). Waxy prisms, insol. water, v. sol. ether. Ammonia forms benzamide and ammonium thiobenzoate. Alcoholic KOH forms KOBz and KSBz. Alcoholic KSH forms KSBz.

Benzoyl disulphide $(C_6H_5CO)_2S_2$. Mol. w. 274. [128°]. Formed from $C_6H_5.CO.SH$ by atmospheric oxidation of its solution in CS_2 (Cloez, *A.* 115, 27), or by treatment with iodine, Fe_2Cl_6, or HNO_3. Also, together with Bz_2S, by warming BzCl with PbS and ether (Mosling, *A.* 118, 304). When heated above its melting-point it turns violet. Prisms or tables (from CS_2), sl. sol. boiling ether and alcohol. Insol. water, NH_4Aq, and KOHAq. Alcoholic KOH forms KOBz and KSBz. Alcoholic KHS forms KSBz.

BENZOYL SULPHOCYANIDE C_6H_5COSCN. S.G. ^{16} 1·20. From BzCl and $Pb(SCN)_2$ in the cold (Miguel, *A. Ch.* [5] 11, 300). Pungent liquid. Decomposed by boiling water into benzamide and COS. On long standing it deposits an isomeride [160°], which is decomposed by water at 200° into NH_3, benzoic acid, and H_2S.

BENZOYL-TARTARIC ACID *v.* TARTARIC ACID.

BENZOYL-TEREPHTHALIC ACID *v.* BENZOPHENONE DICARBOXYLIC ACID.

BENZOYL THIOARSENITE $C_{21}H_{15}AsS_3O_3$ *i.e.* $As(SBz)_3$. [179°]. From BzCl and As_2S_3. An ammoniacal solution gives with $HgCl_2$ a pp. of $Hg(SBz)_2$ (Rayman, *Bl.* [2] 47, 896).

BENZOYL-THIO-CARBAMIC ACID $C_8H_7NSO_2$. *Methyl ether* $Bz.NH.CO.S.Me$. [97°]. From benzoyl sulphocyanide and methyl alcohol (Miguel, *A. Ch.* [5] 11, 330). Slender needles (from dilute alcohol). Sl. sol. water, v. sol. alcohol. Water in large excess at 100° forms $BzNH_2$, methyl alcohol, H_2S, and CO_2. Salt.—$BzNNa.CO.SMe$. From the ethereal [illegible] and MeONa.

Ethyl ether $BzNH.CO.SEt$. [74°]. From BENZOYL [illegible]Et; or from alcohol, BzCl, and KSCN (Lössner, *J. pr.* [2] 10, 235). Long needles; v. sl. sol. water, v. sol. alcohol. Boiling KOHAq forms KOBz, KSCN, alcohol, CO_2, NH_3, and H_2S. Heated alone it gives benzonitrile, CO, and mercaptan. Salt.—$BzNK.CO.SEt$: needles.

BENZOYL THIOCYANATE *v.* BENZOYL SULPHOCYANIDE.

BENZOYL-THIO-UREA *v.* THIO-UREA.

BENZOYL-THYMOL *v.* THYMOL.

BENZOYL-TOLUENE-SULPHAMIDE *v.* TOLUENE SULPHONIC ACID.

BENZOYL-TOLUIDE *v.* TOLUIDINE.

BENZOYL-TOLUIDINE-IMIDE-CHLORIDE *v.* ω-CHLORO-BENZYLIDENE-TOLUIDENE.

BENZOYL-TOLYLENE-DIAMINE *v.* TOLYLENE-DIAMINE.

BENZOYL-TROPEÏNE *v.* TROPIN.

BENZOYL-UREA *v.* UREA.

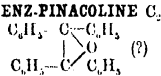
BENZOYL-URITIC ACID *v.* PHENYL TOLYL KETONE DI-CARBOXYLIC ACID.

a-BENZOYL-VALERIC ETHER *v.* *Propyl-*BENZOYL-ACETIC ETHER.

BENZOYL-XYLENE *v.* PHENYL XYLYL KETONE.

BENZOYL-XYLIDE *v.* XYLIDINE.

(α)-BENZ-PINACOLINE $C_{26}H_{20}O$ *i.e.*



(?) [204°].

Tetra-phenyl-ethylene oxide.

Formation.—1. Together with the (β)-modification by boiling a 5 p.c. alcoholic solution of benzophenone with zinc and HCl (Thörner a. Zincke, *B.* 11, 65).—2. Together with benzpinacone by heating an alcoholic solution of benzophenone with zinc and H_2SO_4 (Thörner a. Zincke, *B.* 11, 1396).—3. By the action of zinc-dust on an ethereal solution of acetyl chloride (1 mol.) and benzophenone (1 mol.). If the acetyl chloride is used in excess the (α)-benzpinacoline first formed is converted into the (β)-benz-pinacoline (Paal, *B.* 17, 911).—4. By the oxidation of tetra-phenyl-ethylene with chromic mixture (Behr, *B.* 5, 277).

Properties.—Needles. Almost insoluble in cold alcohol and in cold acetic acid.

Reactions.—1. By acetyl chloride, HCl or H_2SO_4, it is converted into the (β)-modification. 2. By heating with soda lime it gives a hydrocarbon [244°] which is possibly tetraphenyl-ethylene.—3. By CrO_3 and acetic acid it is oxidised to benzophenone.

(β)-Benz-pinacoline $(C_6H_5)_3C.CO.C_6H_5$ [179°] (T. a. Z.); [182°] (Zagumenny).

Formation.—By boiling a concentrated solution of benzophenone in alcohol with zinc and HCl for 20 hours (Thörner a. Zincke, *B.* 10, 1473; 11, 65).—2. From benzpinacone and AcCl or BzCl (Linnemann, *A.* 133, 28).—3. From benzpinacone and dilute H_2SO_4 or HCl at 200°. It is even slowly formed by repeatedly recrystallising benzpinacone from hot alcohol (Z.).—4. From (α)-benzpinacoline by heating with AcCl, HCl, or H_2SO_4.

Preparation.—HClAq is added to a saturated solution of benzpinacone in HOAc until a turbidity appears. The mixture is boiled 45 minutes, with gradual addition of HClAq (Zagumenny, *Bl.* [2] 34, 329; 35, 560).

ether. This indicates the presence of *hydroxyl* in di-bromo-aceto-acetic ether.

(4) The action of ammonia, and especially of di-ethylamine.

In favour of Frankland's formula may be noted the compounds with $NaHSO_3$, phenyl-hydrazine, and hydroxylamine.

The action of sodium upon aceto-acetic ether would be represented by Frankland's formula, thus:

$$CH_3.CO.CH_2.CO_2Et+Na=CH_3.CO.CNaH.CO_2Et+H.$$

Ethyl iodide converts the product into ethyl-aceto-acetic ether:

$$CH_3.CO.CNaH.CO_2Et+EtI=CH_3.CO.CEtH.CO_2Et+NaI$$

These two reactions may be repeated upon the ethyl-aceto-acetic ether:

$$CH_3.CO.CEtH.CO_2Et+Na=CH_3.CO.CEtNa.CO_2Et+H$$
$$CH_3.CO.CEtNa.CO_2Et+EtI=CH_3.CO.CEt_2.CO_2Et+NaI.$$

Adopting Geuther's formula, the four equations become:

$$CH_3.C(OH):CH.CO_2Et+Na=CH_3.C(ONa):CH.CO_2Et+H$$
$$CH_3.C(ONa):CH.CO_2Et+EtI=CH_3.C(OEt):CH.CO_2Et+NaI$$
$$CH_3.C(OEt):CH.CO_2Et+Na=CH_3.C(OEt):CNa.CO_2Et+H$$
$$CH_3.C(OEt):CNa.CO_2Et+EtI=CH_3.C(OEt):CEt.CO_2Et+NaI$$

It will be seen that the third and fourth equations are similar to the first and second on Frankland's hypothesis, but different in kind to the first and second if Geuther's hypothesis be accepted. Such a difference is not borne out by experiment. Thus if it be held that the action of sodium upon aceto-acetic ether depends upon its affinity for oxygen, the third equation presents a difficulty. And if we suppose that, owing to some intra-molecular change, the third equation ought to be written thus:

$$CH_3.C(OEt):CH.CO_2Et+Na=CH_3.C(ONa):CEt.CO_2Et+H$$

then by the action of acetic acid on the product we ought to get an ether $CH_3.C(OH):CEt.CO_2Et$ isomeric, not identical, with ethyl-aceto-acetic ether, $CH_3.C(OEt):CH.CO_2Et$; but the two ethers are found to be identical (James, *C. J.* 47, 1). Inasmuch as the change of $CH_3.C(OH):CEt.CO_2Et$ into $CH_3.C(OEt):CH.CO_2Et$ would be contrary to all analogy, it is necessary, if we adopt Geuther's formula, to assume that the mode of formation of di-ethyl-aceto-acetic ether is something very different from that of ethyl-aceto-acetic ether. Again Geuther's formula would make methyl-ethyl-aceto-acetic ether, $CH_3.C(OEt):CMe.CO_2Et$ and ethyl-methyl-aceto-acetic ether, $CH_3.C(OMe):CEt.CO_2Et$ isomeric, yet this does not appear to be the case (James).

It may be said that there is some improbability in the assumption required by Frankland's formula, of direct union between sodium and carbon, but such a union is known to occur in sodium acetylide and sodium ethide, and it is very probable in many cases, such as sodio-malonic ether, sodium nitro-ethane, and sodic barbiturate. In order that hydrogen attached to carbon may be displaceable by metals, it is necessary that very powerful chlorous groups should also be attached to the carbon, such as the nitroxyl in nitro-ethane. One carbonyl, CO, is not sufficient to produce an acid, but two are. Thus the hydrogen in the group $CO.CH_2.CO$ is displaceable by metals, as in barbituric acid,

$$CO\begin{matrix}\diagup NH.CO \diagdown \\ \diagdown NH.CO \diagup\end{matrix}CH_2.$$

These considerations account for the acidity of aceto-acetic ether, if we assume Frankland's formula $CH_3.CO.CH_2.CO.OH$.

Although the existence of acetyl-aceto-acetic ether favours Geuther's hypothesis, yet the fact that this body is a strong acid is wholly opposed to that view, and is very much better explained by the formula $CH_3.CO.CH(CO.CH_3).CO.OEt$, since if two carbonyls can make the group CH_2 acid, *à fortiori* three carbonyls can have a similar effect.

The formation of ethyl and di-ethyl-acetone from ethyl-aceto-acetic ether and di-ethyl-aceto-acetic ether respectively cannot be explained on Geuther's hypothesis.

If, therefore, we have to choose between one formula and the other, the balance of evidence would indicate $CH_3.CO.CH_2.CO_2Et$.

Methyl aceto-acetate $C_5H_8O_3$ *i.e.* $CH_2Ac.CO_2Me$ (170° cor.) S.G. ^{0} 1·037 (Brandes, *J.Z.* 3, 25). From sodium and methyl acetate. Gives a cherry-red colour with Fe_2Cl_6. Boiled with acids or strong bases it gives CO_2, acetone, and MeOH.

Salts.—$CH_3.CO.CHNa.CO_2Me$. Sl. sol. ether. —$Cu(C_5H_7O_3)_2 2aq$. Separates on adding cupric acetate and baryta water to the ether as pale green crystals, insoluble in alcohol.

Iso-butyl aceto-acetate $C_8H_{14}O_3$ *i.e.* $CH_2Ac.CO_2C_4H_9$ (202°-206°) S.G. ^{0} ·979; ^{22} ·932. From iso-butyl acetate and sodium.

Iso-amyl aceto-acetate $C_9H_{16}O_3$ *i.e.* $CH_2Ac.CO_2C_5H_{11}$ (223°) S.G. $\frac{10}{17.5}$ ·954. From iso-amyl acetate and Na (Conrad, *A.* 186, 228). Converted by Cl into an oily di-chloro-derivative (Conrad, *A.* 186, 243) and by NH_3 into the imide of aceto-acetate of iso-amyl [190°-195°] (Collie, *A.* 226, 319).

ALKYLATED ACETO-ACETIC ETHERS.

Sodium aceto-acetic ether is converted by alkyl iodides into mono-alkyl aceto-acetic ethers, $CH_3.CO.CXH.CO_2Et$. The sodium derivatives of these are in like manner converted by alkyl iodides into di-alkyl-aceto-acetic ethers, $CH_3.CO.CXY.CO_2Et$. Such ethers are of great service in organic syntheses, for they are split up by weak alkalis into carbonic acid and mono- or di-alkyl acetones: $CH_3.CO.CXY.CO_2Et+2KOH=CH_3.CO.CXYH+HOEt+K_2CO_3$, and by strong potash into mono- or di-alkyl-acetic acid and acetic acid: $CH_3.CO.CXY.CO_2Et+2KOH=CH_3.CO_2K+HCXY.CO_2K+HOEt$.

In practice the ketonic and acetic decompositions both occur, at the same time, but the acetic decomposition increases with the concentration of the alkali (Wislicenus, *A.* 206, 308).

Preparation.—The alkyl-aceto-acetic ethers are prepared by dissolving the calculated quantity of sodium in 10 times its weight of absolute alcohol, cooling, adding the aceto-acetic ether and then the alkyl iodide until the liquid, which may be warmed, if necessary, is neutral to litmus. The greater part of the alcohol is then distilled off and water is added. This dissolves the NaI and the new ether rises as an oil and is fractionated (Conrad a. Limpach, *A.* 192, 154).

A. WITH ONE MONOVALENT RADICLE.

Methyl-aceto-acetic Acid $C_5H_8O_3$ *i.e.* $CH_3.CO.CHMe.CO_2H$. A thick liquid which splits up on warming into CO_2, and methyl ethyl ketone (Ceresole, *B.* 15, 1874). Its barium salt is soluble and gives a violet colour with Fe_2Cl_6. Nitrous acid forms iso-nitroso-methyl-ethyl-ketone.

Methyl Ether $CH_3.CO.CHMe.CO_2Me$

(177·4° cor.) S.G. ^{0} 1·020 (Brandes, *Z.* 1866, 458). From sodium aceto-acetate of methyl and MeI. Smells like mint. Gives a violet-red colour with $\mathrm{Fe_2Cl_6}$.

Ethyl Ether $\mathrm{CH_3.CO.CHMe.CO_2Et}$ (186·8° cor.) (Geuther, *Z.* 1866, 5). S.G. ^{0} 1·009. Gives a deep blue colour with $\mathrm{Fe_2Cl_6}$.

Reactions.—1. *Sodium amalgam* gives an oxy-valeric acid $\mathrm{CH_3CH(OH).CHMe.CO_2H}$.—2. *Potash* forms methyl-ethyl ketone, alcohol and $\mathrm{K_2CO_3}$.—3. $\mathrm{PCl_5}$ gives chloro-methyl-crotonic acid [69·5°] (206°) (Rücker), chloro-methyl-aceto-acetic ether, $\mathrm{C_7H_{11}ClO_3}$ (180°) S.G. ^{15} 1·093, smelling of peppermint, and di-chloro-methyl-aceto-acetic ether (210°–220°) S.G. ^{17} 1·225 (Isbert, *A.* 234, 188).—4. Sodium and *cyanogen chloride* form cyano-methyl-aceto-acetic ether $\mathrm{CAcMeCy.CO_2Et}$ (c. 93°) at 20 mm. S. G. ^{22} ·996. It is a colourless liquid insol. water and alkalis (Held, *C. R.* 95, 522; *Bl.* [2] 41, 330).

Acetyl derivative $\mathrm{C_9H_{14}O_4}$ *i.e.* $\mathrm{CMeAc_2CO_2Et}$. *Methyl-diacetyl-acetic ether* (205°–220°). From methyl-aceto-acetic ether in ethereal solution and AcCl (James, *A.* 226, 219, *C. J.* 47, 1). Sl. sol. water. Coloured raspberry red by $\mathrm{Fe_2Cl_6}$. Does not pp. cupric acetate, even on addition of dilute NaOH.

Ethyl-aceto-acetic acid.

Methyl ether $\mathrm{CH_3.CO.CEtH.CO_2Me}$ (189·7° cor.) S. G. ^{14} ·995 (Brandes, *Z.* 1866, 457), $\mathrm{Fe_2Cl_6}$ gives deep violet colour. Conc. $\mathrm{NH_3}$ forms an oil $\mathrm{C_7H_{13}NO_2}$, the imide of ethyl-aceto-acetate of methyl insoluble in water, and also silky needles [83°] of a soluble amide (probably $\mathrm{C_6H_{11}NO_2}$ see below) (Brandes, *Z.* 1866, 457).

Ethyl ether $\mathrm{C_8H_{14}O_3}$ *i.e.* $\mathrm{CAcEtH.CO_2Et}$ (198° cor.) S.G. ^{12} ·998 (G.); $\frac{18}{4}$ ·983 (F. D.) (Geuther, *Ar. Ph.* [2] 116, 97; Frankland a. Duppa, *C. J.* [2] 4, 396; Wislicenus, *A.* 186, 187).

Preparation.—Aceto-acetic ether is dissolved in benzene and four-fifths of the calculated quantity of sodium added, then EtI, and the product rectified. The aceto-acetic ether recovered is treated with the remaining fifth of the sodium. Yield 70 per cent. (Wedel, *A.* 219, 100).

Properties.—An oil. Coloured blue by $\mathrm{Fe_2Cl_6}$.

Reactions.—1. Reduced by *sodium amalgam* to an oxy-hexoic acid, $\mathrm{CH_3.CH(OH).CHEt.CO_2H}$. 2. Boiled with *baryta* or weak alcoholic KOH, it gives methyl propyl ketone.—3. Boiled with conc. alcoholic KOH, or heated with dry NaOEt, it gives *n*-butyric acid and acetic acid, or their ethers.—4. Treated with NaOEt and *cyanogen chloride* it forms *cyano-ethyl-aceto-acetic ether*, $\mathrm{CH_3.CO.CEtCy.CO_2Et}$ (c. 105°) at 20 mm. S.G. ^{22} ·976. A colourless liquid with agreeable odour. Insol. in water or alkaline solutions, miscible with alcohol or ether (Held, *C. R.* 98, 522, *Bl.* [2] 41, 330).—5. *Bromine* acting on an ethereal solution forms mono- di- and tri- BROMO-ETHYL-ACETO-ACETIC ETHER (*q. v.*).—6. $\mathrm{PCl_5}$ gives mono- and di- CHLORO-ETHYL-ACETO-ACETIC ETHER, and only one CHLORO-ETHYL-CROTONIC ACID (*q. v.*) (Isbert, *A.* 234, 183).—7. *Benzoic aldehyde* and HCl form same benzylidene-ethyl-aceto-acetic ether or cinnamoyl-ethyl-acetic ether, $\mathrm{Ph.CH{:}CH.CO.CHEt.CO_2Et}$ (210°) at 22 mm. Converted by NaOEt and EtI into cinnamoyl-di-ethyl-acetic ether.—8. Conc. aqueous *ammonia* forms two amides, one soluble in water, $\mathrm{C_6H_{11}NO_2}$, the other insoluble, $\mathrm{C_8H_{15}NO_2}$. They are formed in equi-molecular quantities; the oily insoluble amide crystallises when cooled. On distilling the soluble amide does not pass over with steam.

Insoluble amide $\mathrm{C_8H_{15}NO_2}$ imide of ethyl-aceto-acetic ether $\mathrm{CH_3.C(NH).CHEt.CO_2Et}$ or $\mathrm{CH_3.C(NH_2){:}CEt.CO_2Et}$ [59·5°]. Monoclinic tablets (from alcohol), smelling of peppermint. Decomposed by water, or dilute acids, into $\mathrm{NH_3}$ and ethyl-aceto-acetic ether (Geuther, *Z.* 1871, 247).

Soluble amide $\mathrm{C_6H_{11}NO_2}$ *i.e.* $\mathrm{CAcHEt.CONH_2}$ [90°]. Needles (from water, alcohol, or ether). May be sublimed. May be obtained from the preceding body by heating with water at 135°. On dry distillation it gives $\mathrm{NH_3}$, $\mathrm{CO_2}$ and methyl propyl ketone. The latter body is also formed by heating it with water at 200°, with boiling aqueous HCl, with $\mathrm{CaCl_2}$, $\mathrm{ZnCl_2}$, $\mathrm{P_2O_5}$, or $\mathrm{PCl_5}$ (Isbert takes it to be di-ethyl ketone). Heated with dry KOH at 100° it forms butyric and acetic acids (Isbert, *A.* 234, 170).

Salts.—$\mathrm{CH_3.CO.CNaEt.CO_2Et}$. Formed by adding sodium to a solution of ethyl-aceto-acetic ether in dry ether or benzene (3 or 4 vols.) (J. W. James, *C. J.* 47, 1). Also by shaking an ethereal solution of the ether with perfectly dry NaOH (Elion, *R.* 3, 234). It is amorphous. V. sol. ether. A little water added to its ethereal solution forms a pp. of $\mathrm{CH_3.CO.CNaEt.CO_2Et}$ aq, insol. ether or benzene, but sol. water or alcohol. Acetic acid re-converts the sodium salt into ethyl-aceto-acetic ether (v. *constitution* of ACETO-ACETIC ETHER).

Ethyl aceto-acetic ether forms no copper compound. This is thought to favour the formula $\mathrm{CH_3.C(OEt){:}CH.CO_2Et}$.

Iso-amyl ether $\mathrm{CH_3.CO.CHEt.CO_2C_5H_{11}}$ (233°–236°) S.G. $\frac{20}{17\cdot5}$ ·937 gives no colour with $\mathrm{Fe_2Cl_6}$ (Conrad, *A.* 186, 228).

Acetyl derivative $\mathrm{CH_3.CO.CAcEt.CO_2Et}$. *Ethyl-di-acetyl-acetic ether* (c. 230°); (144°–150°) at 50 mm. S.G. ^{15} 1·034. From $\mathrm{CH_3.CO.CNaEt.CO_2Et}$ and AcCl (Elion, *R.* 3, 265). Liquid. Insol. KOHAq. Gives no colour with $\mathrm{Fe_2Cl_6}$. Alcoholic $\mathrm{NH_3}$ converts it into acetamide and $\mathrm{CH_3.CO.CHEt.CO_2Et}$.

Allyl-aceto-acetic Ether $\mathrm{C_9H_{14}O_3}$ *i.e.* $\mathrm{CH_3.CO.CH(C_3H_5).CO_2Et}$ (206°) (Zeidler, *A.* 187, 33) (214° cor.) at 720 mm. (Perkin, *C. J.* 45, 540). S.G. $\frac{20}{17\cdot5}$ ·982 (*Z.*); $\frac{15}{15}$ ·993; $\frac{25}{25}$ ·985 (P.). From sodium aceto-acetic ether and allyl iodide (*Z.*; Wolff, *A.* 201, 46). From aceto-acetic ether, allyl iodide, and zinc, di-allyl-aceto-acetic ether being also formed (O. Hofmann, *A.* 201, 77).

Reactions.—1. $\mathrm{Fe_2Cl_6}$ gives a crimson colour. 2. Boiling alcoholic KOH forms $\mathrm{CO_2}$ and allyl-acetone.—3. Dry NaOEt at 150°–160° gives ethyl acetate and allyl-acetate.—4. *Sodium amalgam* forms an oxy-heptenoic acid,

$$\mathrm{CH_3.C(OH)H.CH(C_3H_5)CO_2H}.$$

Propyl-aceto-acetic Ether $\mathrm{C_9H_{16}O_3}$ *i.e.* $\mathrm{CH_3.CO.CHPr.CO_2Et}$ (209°) S.G. $\frac{0}{4}$ ·981. From aceto-acetic ether (153g.) by adding first a solution of sodium (27g.) in dry alcohol (270g.) and then PrI (206g.) (Burton, *Am.* 3, 385). Decomposed by aqueous KOH into $\mathrm{CO_2}$, alcohol, and methyl butyl ketone.

Iso-propyl-aceto-acetic Ether $\mathrm{C_9H_{16}O_3}$ *i.e.* $\mathrm{CH_3.CO.CPrH.CO_2Et}$ (201°) at 758 mm. S.G. ^{2} ·880. From sodium aceto-acetic ether and isopropyl iodide (Frankland a. Duppa, *A.* 145, 78).

Coloured pale reddish-violet by Fe$_2$Cl$_6$ (Demarçay, *Bl.* 27, 224).

Iso-butyl-aceto-acetic Ether C$_{10}$H$_{18}$O$_3$ *i.e.* Pr.CH$_2$CHAc.CO$_2$Et (218°) S.G. $\underline{17\cdot5}$ ·951. From sodium aceto-acetic ether and iso-butyl iodide (Rohn, *A.* 190, 306). Decomposed by baryta giving methyl iso-amyl ketone and iso-butyl-acetic (hexoic) acid.

Heptyl-aceto-acetic Ether C$_{13}$H$_{24}$O$_3$ *i.e.* CH$_3$.CO.CH(C$_7$H$_{15}$).CO$_2$Et (272°) S.G. $\frac{17\cdot7}{17\cdot7}$ ·9324. From sodium aceto-acetic ether and heptyl iodide (Jourdan, *A.* 200, 105). Colourless oil. Decomposed by dilute alkalis into methyl octyl ketone and CO$_2$; and by conc. alkalis into acetic and *n*-ennoic acids.

Secondary Heptyl-aceto-acetic Ether (250°–260°). Prepared similarly from secondary heptyl iodide (Venable, *B.* 13, 1651).

Octyl-aceto-acetic Ether C$_{14}$H$_{26}$O$_3$ *i. e.* CH$_3$.CO.C(C$_8$H$_{17}$)H.CO$_2$Et (281°) S.G. $\frac{18\cdot5}{17\cdot5}$ ·9354. From octyl iodide and sodium aceto-acetic ether (Guthzeit, *A.* 204, 1). Decomposed by alcoholic KOH into methyl ennyl ketone and decoic acid.

Benzyl-aceto-acetic Ether C$_{13}$H$_{16}$O$_3$ *i.e.* CH$_3$.CO.CH(CH$_2$Ph)CO$_2$Et (276°) S.G. $\frac{15\cdot5}{16\cdot5}$ 1·036. From sodium aceto-acetic ether and benzyl chloride (Ehrlich, *B.* 7, 690; *A.* 187, 12; Conrad, *B.* 11, 1056). Sodium amalgam gives exo-oxy-phenyl-valeric acid CH$_3$.CH(OH).CH(CH$_2$Ph).CO$_2$Et. Alcoholic KOH forms phenyl-ethyl methyl ketone.

B. WITH TWO DI-VALENT RADICLES:

Ethylene-aceto-acetic Acid. CH$_3$.CO.C(C$_2$H$_4$).CO$_2$H. From the ether by saponification. Liquid. Decomposed by heat or by dilute acids into tri-methylene methyl ketone

$$\mathrm{CH_3.CO.CH}\left\langle\begin{matrix}\mathrm{CH_2}\\ |\\ \mathrm{CH_2}\end{matrix}\right. \text{ and } \mathrm{CO_2}.$$

Salt.—AgA′.

Ethyl ether.—EtA′ (193°–195°). From aceto-acetic ether (26g.) by adding a solution of sodium (5g.) in alcohol followed by ethylene bromide (38g.) The liquid is boiled for eight hours, filtered, and distilled. The residue is boiled for twelve hours longer with a solution of sodium (5g.) in alcohol, evaporated, and treated with water. The ether is extracted by ether and dried over K$_2$CO$_3$ (W. H. Perkin, jun., *C.J.* 47, 834; *B.* 16, 2136; 19, 1247). It reacts with phenyl-hydrazine, forming an oil.

Ethylidene-aceto-acetic Ether. CH$_3$.CH:CAc.CO$_2$Et (210°–212°) S.G. $\underline{15}$ 1·023 By passing HCl into aldehyde (1 pt.) mixed with aceto-acetic ether (3 pts.) (L. Claisen a. F. H. Matthews, *A.* 218, 172; Claisen, *B.* 14, 345).

Pungent ethereal oil. Miscible with H$_2$SO$_4$.

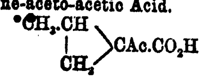
Reactions.—1. Hot potash decomposes it, forming aldehyde.—2. Combines with bromine.

Tri-chloro-ethylidene-aceto-acetic Ether. CCl$_3$.CH : CAc.CO$_2$Et. S.G. $\underline{15}$ 1·342

From chloral, aceto-acetic ether and Ac$_2$O at 160°. (Claisen a. Matthews, *A.* 218, 175).

Thick oil. Decomposed by heat.

Propylene-aceto-acetic Acid.

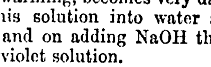


$$\left.\begin{matrix}\mathrm{CH_3.CH}\\ |\\ \mathrm{CH_2}\end{matrix}\right\rangle\mathrm{CAc.CO_2H}$$

From the ether by saponification. Oil. Forms an amorphous silver salt, AgA′.

Ethyl ether (210°–215°) at 720 mm. Aceto-acetic ether (26g.) is heated with sodium (4·6g.), dissolved in dry alcohol and propylene bromide (40g.) at 100°. After two days the tubes are opened and a fresh quantity of alcoholic NaOEt (from 4·6g. sodium) is added, and the tubes heated again at 100° (Perkin, jun., *B.* 17, 1443).

Tri-methylene Bromide acts on aceto-acetic ether in presence of NaOEt, but the product C$_9$H$_{14}$O$_3$ (V.D. 6·21) is not tri-methylene-aceto-acetic ether, for its boiling point (223°) and molecular magnetic rotation, 10·195, are both too high, and it does not react with phenyl-hydrazine. It is, however, the ether of a crystalline acid which splits up on distillation into CO$_2$ and C$_6$H$_{10}$O, and on boiling with water into CO$_2$ and acetyl-butyl alcohol. The acid is probably



$$\mathrm{CH_2}\left\langle\begin{matrix}\mathrm{C(CO_2H):CMe}\\ \qquad\qquad |\\ \mathrm{CH_2.CH_2.O}\end{matrix}\right.$$

(Perkin, jun., *B.* 16, 208, 1789; 19, 1247, 2557).

Iso-butylidene-aceto-acetic Ether (CH$_3$)$_2$CH.CH:CAc.CO$_2$Et (219°–222°). From isobutyric aldehyde, aceto-acetic ether and HCl (Claisen a. Matthews, *A.* 218, 174).

Liquid smelling of peppermint.

Iso-amylidene-aceto-acetic Ether. (CH$_3$)$_2$CH.CH$_2$.CH:CAc.CO$_2$Et (237°–241°) S.G. $\underline{15}$ ·961. From valeric aldehyde, aceto-acetic ether and HCl (Claisen a. Matthews, *A.* 218, 174).

Benzylidene-aceto-acetic Ether Ph.CH : CAc.CO$_2$Et (α-aceto-cinnamic ether), [60°] (180°–182°) at 17 mm. (295°–297°) at 760 mm. From aceto-acetic ether, benzoic aldehyde and gaseous HCl at 0°. (Claisen a. Matthews, *A.* 218, 177) 4 or 6 sided tables (from alcohol); trimetric, a : b : c = ·447 : 1 : ·962. Colourless oil, solidifying very slowly. V. sol. chloroform, m. sol. cold alcohol, ether, glacial acetic acid or CS$_2$, v. sl. sol. benzoline. Insoluble in aqueous KOH. H$_2$SO$_4$ forms a bright yellow solution which, on warming, becomes very dark red. On pouring this solution into water a white pp. is formed, and on adding NaOH this dissolves, forming a violet solution.

Reactions.—Bromine in ether forms a di-bromide [97°]. This forms short needles (from benzoline).

Theory of the Process.—Benzoic aldehyde probably first combines with HCl forming Ph.CH(OH)Cl, and this reacts with aceto-acetic ether thus:

$$\mathrm{Ph.CHCl(OH) + CH_2Ac.CO_2Et =}$$
$$\mathrm{H_2O + Ph.CHCl.CHAc.CO_2Et.}$$

Two compounds of this formula may be isolated before distillation, one forms prisms [41°], the other small rhombohedra or triclinic tables [72°] (both from benzoline). They are both unstable, giving off HCl. One of them has probably the formula Ph.CHCl.CHAc.CO$_2$Et and decomposes into HCl and Ph.CH:CAc.CO$_2$Et, which recombines with HCl forming the other Ph.CH$_2$.CClAc.CO$_2$Et. On distillation both probably give HCl and benzylidene-aceto-acetic ether.

Benzylidene-ethyl-aceto-acetic Ether Ph.CH:CH.CO.CHEt.CO$_2$Et (205°–220°) at 22 mm. (Cinnamoyl-ethyl-acetic ether). From benzoic aldehyde, ethyl-aceto-acetic ether, and HCl. Yield small (Claisen a. Matthews, *A.* 218, 184).

Benzylidene-di-ethyl-aceto-acetic Ether

$Ph.CH{:}CH.CO.CEt_2.CO_2Et$

[101°-103°]. *Formation.*—(1) From the above, NaOEt, and EtI.—(2) From benzoic aldehyde, di-ethyl-aceto-acetic ether, and HCl (C.M.). Triclinic prisms (from benzoline). V. sol. ether or chloroform, m. sol. cold alcohol or benzoline. *Dibromide* [55°].

Furfural-aceto-acetic Ether

$(C_5H_4O)''CAc.CO_2Et$

[62·5°]. (189°) at 30 mm. From furfur-aldehyde, aceto-acetic ether, and Ac_2O at 160°. (Claisen a. Matthews, *A.* 218, 176.) Trimetric crystals, a : b : c = ·439 : 1 : ·465. V. sol. alcohol, glacial acetic acid, chloroform, and benzene. M. sol. ether, sl. sol. benzoline.

C. WITH TWO MONOVALENT RADICLES.

Di-methyl-aceto-acetic Acid

$C_6H_{10}O_3$ *i.e.* $CH_3.CO.CMe_2.CO_2H$.

From the ether by dissolving in cold dilute (2½ per cent.) aqueous KOH, setting aside for a day or two, then acidifying with H_2SO_4, extracting with ether, evaporating the ether, and triturating with $BaCO_3$. The crystalline barium salt, BaA'_2, is decomposed by dilute H_2SO_4 (Ceresole, *B.* 15, 1871). Very hygroscopic crystals, which slowly split up into CO_2 and methyl isopropyl ketone. The barium salt gives a brown colour or pp. with Fe_2Cl_6. It reduces boiling silver nitrate.

Ethyl Ether

$C_8H_{14}O_3$ *i.e.* $CH_3.CO.CMe_2.CO_2Et$

(184°) S.G. $\frac{16}{}$ ·991. From sodium methyl-aceto-acetic ether and MeI (Frankland a. Duppa, *A.* 138, 328). Potash or baryta splits it up into alcohol, CO_2, and methyl iso-propyl ketone.

Methyl-ethyl-aceto-acetic Ether

$CH_3.CO.CMeEt.CO_2Et$

(196° uncor.) (*J.*) (201° i. V.) (Wislicenus, *A.* 219, 308). S.G. $\frac{22}{17.5}$ ·947. From sodium ethyl-aceto-acetic ether and MeI (Saur, *A.* 188, 257); or sodium methyl-aceto-acetic ether and EtI (J. W. James, *A.* 226, 209; *C. J.* 47, 1). Oil. Fe_2Cl_6 gives a violet colour. Distilled with dry NaOEt it gives ethyl acetate and ethyl methyl-ethyl-acetate (or valerate).

Methyl-allyl-aceto-acetic Ether

$C_{10}H_{16}O_3$ *i.e.* $CH_3.CO.CMe(C_3H_5)CO_2Et$

(c. 209°-211°). From allyl-aceto-acetic ether, MeI, and NaOEt (James, *C. J.* 47, 3). Pleasant-smelling oil, miscible with alcohol, ether, or benzene. Fe_2Cl_6 gives no colour. The same body may be got from methyl-aceto-acetic ether, allyl iodide, and NaOEt.

Methyl-propyl-aceto-acetic Ether

$C_{10}H_{18}O_3$ *i.e.* $CH_3.CO.CMePr.CO_2Et$

(214°) (L.K.); (216°) (J.). S.G. $\frac{15}{}$ ·959 (L.K.); $\frac{17}{4}$ ·9575 (J.). From methyl-aceto-acetic ether, NaOEt, and PrI (Liebermann a. Kleemann, *B.* 17, 918) or from propyl-aceto-acetic ether, NaOEt, and MeI (E. J. Jones, *A.* 226, 287).

Di-ethyl-aceto-acetic acid

$CH_3.CO.C(C_2H_5)_2.CO_2H$.

Thick colourless liquid. Sl. sol. water.

Preparation.—Di-ethyl-acet-acetic ether is left in the cold for several weeks with 10 p.c. aqueous KOH. After removing the unaltered ether, the product is acidified and extracted with ether, and the acid purified by conversion into the barium salt, acidifying the latter, and again extracting with ether.

Reactions.—It decomposes very slowly in the cold, but on heating to 60° it rapidly evolves CO_2, forming di-ethyl-acetone. The latter body is also formed by distilling the barium salt.

Salts.—A'Na; easily soluble white microscopic crystals.—A'_2Ba 2aq; transparent prisms, rotates on water (Ceresole, *B.* 16, 830).

Ethyl ether $C_{10}H_{18}O_3$ *i.e.* $CH_3.CO.CEt_2.CO_2Et$ (218°). S.G. $\frac{20}{}$ ·974. From sodium ethyl-aceto-acetic ether and EtI (Frankland a. Duppa, *A.* 138, 211; James, *A.* 226, 205). From $Cl.CO_2Et$, Na, and EtI (Geuther a. Matthey, *J. pr.* [2] 6, 160).

Reactions.—1. With hot aqueous *baryta* it gives di-ethyl-acetone.—2. Distilled with dry NaOEt it gives di-ethyl-acetic (hexoic) ether, acetic acid, and sodic di-ethyl-acetate.—3. PCl_5 gives mono- and di-chloro-di-ethyl-aceto-acetic ether and chloro-ethyl-crotonic ether (James, *A.* 231, 235).—4. With *benzoic aldehyde* and HCl gas it forms some $C_6H_5.CH{:}CH.CO.CEt_2.CO_2Et$, cinnamoyl-di-ethyl-acetic ether. Crystals, [102°], (200°-205°) at 3 mm. Easily soluble in ether and chloroform, slightly in cold alcohol and in light petroleum (Matthews, *C. J.* 43, 205). Bromine in chloroform forms a di-bromide, [55°]. Prisms v. sol. alcohol and light petroleum.

Di-allyl-aceto-acetic Ether

$C_{12}H_{18}O_3$ *i.e.* $CH_3.CO.C(C_3H_5)_2CO_2Et$

(240°). S.G. $\frac{25}{17.5}$ ·948. From sodium allyl-aceto-acetic ether and allyl bromide (Wolff, *A.* 201, 45). From aceto-acetic ether, allyl iodide, and zinc (O. Hofmann, *A.* 201, 77). Colourless oil, with faint peculiar odour. Insol. water, sol. alcohol, ether, or benzene. Boiling conc. KOHAq forms di-allyl-acetone, or methyl heptinyl ketone, and di-allyl-acetic acid.

Di-propyl-aceto-acetic Ether $C_{12}H_{22}O_3$ *i.e.* $CH_3.CO.CPr_2.CO_2Et$ (236°). S.G. $\frac{0}{4}$ ·9585. From sodium propyl-aceto-acetic ether and PrI (Burton, *Am.* 3, 386). Alkalis split it up, giving di-propyl-aceto-acetic ether and di-propyl-acetone or methyl heptyl ketone.

Di-isobutyl-aceto-acetic Ether $C_{14}H_{26}O_3$ *i.e.* $(PrCH_2)_2CAc.CO_2Et$ (250°-253°). S.G. $\frac{10}{}$ ·947. From sodium isobutyl-aceto-acetic ether and isobutyl iodide (Mixter, *B.* 7, 500).

Di-*n*-heptyl-aceto-acetic Ether

$C_{20}H_{38}O_3$ *i.e.* $CH_3CO.C(C_7H_{15})_2CO_2Et$

(332°) S.G. $\frac{17.5}{17.5}$ ·891. Formed together with di-heptyl-acetic ether and methyl octyl ketone by heating sodium heptyl-aceto-acetic ether with heptyl iodide and dry alcohol for a long time (Jourdan, *A.* 200, 112). Decomposed by dilute alkalis into CO_2 and methyl pentadecyl ketone, and by concentrated alkalis into acetic and di-heptyl-acetic (hexadecoic) acids.

Di-octyl-aceto-acetic Ether

$C_{22}H_{42}O_3$ *i.e.* $CH_3.CO.C(C_8H_{17})_2.CO_2Et$

(264°) at 90 mm. (340°-342°) at 760 mm. From octyl-aceto-acetic ether, NaOEt, and octyl iodide (Guthzeit, *A.* 204, 9). Decomposed by alkalis into di-octyl-acetone (methyl heptadecyl ketone) and di-octyl-acetic (heptadecoic) acid.

Benzyl-methyl-aceto-acetic Acid

$C_{11}H_{14}O_3$ *i.e.* $CH_3.CO.CMe(CH_2Ph).CO_2H$

[34°] (275°). From the ether by saponification Sl. sol. cold water. *Salt*: AgA'.

Ethyl ether—EtA′ (287°). S.G. $\frac{17}{17}$ 1·046. Prepared by action of MeI on a mixture of benzyl-aceto-acetic acid and sodium ethylate (Conrad, *B.* 11, 1055).

Benzyl ether—PhCH$_2$A′ (53°?). Methyl hydro-cinnamein. Liquid.

Benzyl-ethyl-aceto-acetic Ether

$CH_3.CO.CEt(CH_2Ph).CO_2Et$

(296°). Colourless liquid.

Di-benzyl-aceto-acetic Ether

$CH_3.CO.C(CH_2Ph)_2.CO_2Et.$

From sodium benzyl-aceto-acetic ether and benzyl chloride (Ehrlich, *A.* 187, 24). Thick non-volatile liquid.

OTHER DERIVATIVES of aceto-acetic acid will be described as acetyl derivatives, *e.g.* ACETYL-GLUTARIC ETHER, ACETYL-SUCCINIC ETHER, &c. See also OXY-ACETO-ACETIC ETHER, OXY-DI-ETHYL-ACETO-ACETIC ETHER, OXY-DI-METHYL-ACETO-ACETIC ETHER.

For analogous acids see PROPIONYL-PROPIONIC ACID, VALERYL-VALERIC ACID.

ACETO-BENZOYL-BENZOIC ANHYDRIDE *v.* BENZOYL-BENZOIC ACETIC ANHYDRIDE.

ACETO-BROMO-ACETIC ETHER *v.* BROMO-ACETO-ACETIC ETHER.

ACETO-BROMO-AMIDE *v.* ACETAMIDE.

ACETO-BUTYRIC ACID *v.* ACETYL-BUTYRIC ACID.

ACETO-CHLORO-AMIDE *v.* ACETAMIDE.

ACETO-CHLORHYDRIN *v.* GLYCERIN.

ACETO-CHLORHYDROSE: $C_{14}H_{19}ClO_9$ *i.e.* $C_6H_7Ac_4O_5Cl$. Formed by treating 1 mol. anhydrous glucose with 5 mol. AcCl, and purified by solution in chloroform, agitation with sodium carbonate, and evaporation.—Semifluid; sometimes crystalline. Dextro-gyrate. Bitter. Insol. in water, slightly sol. in CS$_2$, easily in alcohol, ether and chloroform. Distils in a vacuum, partly undecomposed. Gives up all its chlorine to alcoholic silver nitrate. Reduces Fehling's solution. Reconverted into glucose by heating with water (Colley, *C. R.*, 70, 401). H. W.

ACETO-CINNAMONE *v.* BENZYLIDENE-ACETONE.

ACETO-COUMARIC ACID *v.* COUMARIC ACID.

ACETO-CURCUMIN *v.* CURCUMIN.

ACETO-ETHYL NITRATE $C_2H_4O, 2C_2H_5NO_3$ (84°–86°) S.G. ^{15} 1·045. Formed by dry distillation of potassium ethyl-sulphate with potassium nitrate. Liquid, having a sweet taste and aromatic odour. Explodes violently when heated above its boiling point. Not miscible with water. Resolved by heating with potash-lye into aldehyde and nitric acid (Nadler, *A.* 116, 173). H. W.

ACETO-ETHYL-SUCCINIC ACID *v.* ACETYL-ETHYL-SUCCINIC ACID.

ACETO-ETHYL-THIENONE *v.* ETHYL-THIENYL METHYL KETONE.

ACETO-GLYCEROLS *v.* GLYCERIN.

ACETO-TETRA-METHYLENE *v.* TETRAMETHYLENE METHYL KETONE.

ACETO-METHYL-THIENONE *v.* METHYL-THIENYL METHYL KETONE.

ACETONAMINES.

Di-Acetonamine

$C_6H_{13}NO$ *i.e.* $CH_3.CO.CH_2.CMe_2.NH_2$.

Preparation.—1. Dry ammonia-gas is passed into a flask containing boiling acetone, the conducting tube terminating just above the liquid; the resulting mixture of acetone vapour and ammonia is passed through a tube heated to 100°, and then through a condensing tube; the distillate is neutralised with sulphuric acid diluted with an equal volume of water, and, after removing the ammonium sulphate which crystallises out, and distilling off unaltered acetone, the liquid is evaporated to dryness and the residue exhausted with boiling alcohol. Diacetonamine sulphate then crystallises out on cooling, and may be purified by recrystallisation from alcohol (Heintz, *A.* 174, 154).—2. Acetone saturated with ammonia is left to itself for three or four weeks, finely pounded oxalic acid is then added in quantity sufficient to form an acid salt, and a quantity of water equal to that of the acetone. The resulting crystalline precipitate is easily separated by boiling alcohol into insoluble ammonium oxalate and soluble diacetonamine oxalate. A further quantity of this last salt remains in the mother-liquor, together with salts of other bases (Sokoloff a. Latschinoff, *B.* 7, 1384).

Properties.—Free diacetonamine, separated from either of its salts by adding strong soda-lye and agitating with ether, is a colourless liquid lighter than water, having an ammoniacal odour and strong alkaline reaction; more soluble in cold than in hot water, mixes in all proportions with alcohol and ether; oxidises and turns brown on exposure to the air; forms crystalline salts with hydrochloric, sulphuric, and oxalic acids. By distillation it is for the most part resolved into NH$_3$ and mesityl oxide $C_6H_{10}O$, and on the other hand is easily formed by direct combination of these bodies: $C_6H_{10}O + NH_3 = C_6H_{13}NO$.

Salts.—$C_6H_{13}NOHCl$ crystallises from alcohol in rhombic prisms, v. sol. alcohol, resolved by dry distillation into NH$_4$Cl and $C_6H_{10}O$ (Heintz, *A.* 175, 252)—$(C_6H_{13}NO,HCl)_2PtCl_4,2H_2O$ crystallises from water, in which it is easily soluble (according to Sokoloff a. Latschinoff; also in dilute alcohol), in orange-yellow monoclinic prisms containing 2H$_2$O, which they give off in a vacuum (H.); under ordinary pressure (S. and L.). The *normal oxalate* $(C_6H_{13}NO)_2C_2H_2O_4$ forms monoclinic tablets, very soluble in cold water, less soluble in alcohol than the acid salt. This latter $C_6H_{13}NO,C_2H_2O_4,H_2O$, forms monoclinic prisms; very soluble in hot, less in cold, water; easily in boiling alcohol, from which it separates out almost completely on cooling. The *picrate* $C_6H_{13}NO,C_6H_3(NO_2)_3O,H_2O$, forms gold-yellow needles, somewhat sparingly soluble in cold water. The *sulphate* $(C_6H_{13}NO)_2H_2SO_4$ forms monoclinic crystals (from alcohol).

Reactions.—1. HNO$_2$ decomposes the salts forming di-acetone alcohol and mesityl oxide:

$$2C_6H_{13}NO + 2HNO_2 =$$
$$C_6H_{12}O_2 + C_6H_{10}O + 2N_2 + 3H_2O.$$

2. *Chromic acid* mixture converts it into para-formaldehyde together with formic, acetic, and amido-iso-valeric acids $NH_2.CMe_2.CH_2.CO_2H$, and a small quantity of amido-iso-butyric acid $NH_2.CMe_2.CO_2H$ (Heintz, *A.* 198, 45).—3. Solid KOH forms an anhydride, $C_{12}H_{24}N_2O$ [83°]. This is v. sol. alcohol, chloroform, or benzene, m. sol. ether or light petroleum. Hot water decomposes it (Antrick, *A.* 227, 381). It forms a salt, $(C_{12}H_{24}N_2OHCl)_2PtCl_4$, when dry. Small prisms.—4. An aqueous solution of diaceto-

namine hydrochloride heated for ten hours at 120° with aqueous *hydrocyanic acid* forms the hydrochlorides of diacetonamine cyanhydrin and of nitrilo-diacetonamine, together with a little amido-iso-butyric acid (Heintz, *A.* 189, 231; 192, 340).—5. Diacetonamine oxalate boiled with alcoholic solutions of *aldehydes* forms condensation products.—6. *Sodium amalgam* reduces di-acetonamine to a secondary amido-iso-hexyl alcohol $CH_3.CH(OH).CH_2.CMe_2NH_2$.

CYANHYDRINS.

Di-Acetonamine cyanhydrin

$C_7H_{14}N_2O$ or $Me.C(OH)(CN).CH_2.CMe_2.NH_2$.

Carbylo-di-acetonamine.—Prepared as described above (*Reaction* 4).—Trimetric prisms. V. sol. water.. Decomposed by boiling alcohol into HCN and diacetonamine. Boiling HCl saponifies it, forming OXY-AMIDO-HEPTOIC ACID (*q. v.*), $Me.C(OH)(CO_2H).CH_2.CMe_2NH_2$, the greater part of which changes to its anhydride, di-oxy-tri-methyl-pyrroline,

$$\mathrm{MeC(OH)}\begin{array}{l}\diagup\mathrm{CO - NH}\\ \qquad\qquad\;|\\ \diagdown\mathrm{CH_2 - CMe_2}\end{array}$$

(Heintz, *A.* 192, 329; Weil, *A.* 232, 208 *v.* PYRROLINE).

Nitrilo-di-Acetonamine $C_7H_{11}N_2O$. The hydrochloride is obtained, as above stated, together with its isomeride. The free base is crystalline, easily soluble in water, sparingly in ether, and absorbs CO_2 from the air. Distinguished from carbylodiacetonamine by remaining unaltered when heated to 100°–110° with fuming hydrochloric acid. Resolved by boiling with baryta water into NH_3 and amido-trimethyl-oxybutyric acid $C_7H_{15}NO_3$ or its anhydride. The *platinochloride* $(C_7H_{14}N_2O,HCl)_2PtCl_4$ forms yellow rhombic prisms slightly soluble in water. The *oxalate* $C_7H_{14}N_2O,C_2H_2O_4$ forms small crystals m. sol. water, insol. alcohol (Heintz, *A.* 192, 342).

PRODUCTS FROM ALDEHYDES.

Ethylidene-di-acetonamine $C_8H_{15}NO$ or

$$\mathrm{CH_3.CH}\begin{array}{l}\diagup\mathrm{CH_2 . CO}\diagdown\\ \diagdown\mathrm{NH.CMe_2}\diagup\end{array}\mathrm{CH_2}$$

[27°] (200°) *vinyl-di-acetonamine*; *oxy-tri-methyl-tetra-hydro-pyridine.*

Formation.—Together with tri-acetonamine by action of aldehyde and ammonia on acetone. In larger quantity as oxalate, by boiling the acid oxalate of diacetonamine (10 g.) for sixty hours in a reflux apparatus with aldehyde (10 g.) and alcohol (120 g.). The oxalate is washed with hot alcohol, and the free bases separated by potash (Heintz, *A.* 178, 326; 189, 214; 191, 122).

Preparation.—By boiling an alcoholic solution of di-acetonamine oxalate with paraldehyde (E. Fischer, *B.* 17, 1793).

Properties.—Solidifies at –15° to rectangular or six-sided plate [illegible] ong prisms. Is deliquescent. Has a l[illegible]g taste, smells like trimethylamine, but when warmed, like camphor.

Reduced by sodium amalgam to its dihydride or ethenyl-di-acetone-alcamine.

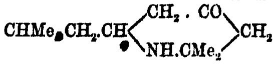
Salts.—$(B'HCl)_2PtCl_4$3aq. Flat prisms.—$B'_2H_2SO_4$. Minute needles, v. sol. water, sl. sol. alcohol.—$B'_2H_2C_2O_4$. Sl. sol. alcohol.—B'_4 $3H_2C_2O_4$.

A platino-chloride of vinyl-di-acetonamine and tri-acetonamine

$(C_8H_{15}NO.HCl + C_9H_{17}NO.HCl)PtCl_4 + 2H_2O$

is formed by direct combination of its constituents. 100 pts. water at 14° dissolve 8·65 pts. of the anhydrous salt (Heintz, *J.* 1877, 442).

Pentylidene-di-acetonamine $C_{11}H_{21}NO$ or



$$\mathrm{CHMe_2.CH_2.CH}\begin{array}{l}\diagup\mathrm{CH_2 . CO}\diagdown\\ \diagdown\mathrm{NH.CMe_2}\diagup\end{array}\mathrm{CH_2}$$

Valeral-di-acetonamine; *oxy-di-methyl-iso-butyl-tetra-hydro-pyridine* [15°–22°]. From valeric aldehyde and alcoholic di-acetonamine oxalate (Antrick, *A.* 227, 367). Needles in stars (from ether). Insol. water, sol. alcohol, ether, benzene, and petroleum.

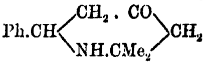
Salts.—$B'_2H_2C_2O_4$. Needles [190°]. V. sl. sol. cold water or alcohol.—$(B'HCl)_2PtCl_4$ [205°].

Heptylidene-di-acetonamine $C_{13}H_{25}NO$ or

$$\mathrm{C_6H_{13}.CH}\begin{array}{l}\diagup\mathrm{CH_2 . CO}\diagdown\\ \diagdown\mathrm{NH.CMe_2}\diagup\end{array}\mathrm{CH_2}$$

Oxy-di-methyl-hexyl-tetra-hydro-pyridine [29·5°]. From œnanth-aldehyde and alcoholic di-acetonamine oxalate (Antrick, *A.* 227, 370). Needles (from ether). *Oxalate* $B'_2 H_2C_2O_4$ [c. 150°].

Benzylidene-di-acetonamine $C_{13}H_{17}NO$ or



$$\mathrm{Ph.CH}\begin{array}{l}\diagup\mathrm{CH_2 . CO}\diagdown\\ \diagdown\mathrm{NH.CMe_2}\diagup\end{array}\mathrm{CH_2}$$

Oxy-phenyl-di-methyl-tetra-hydro-pyridine [61°] (230°). Obtained as oxalate, by boiling 1 pt. benzaldehyde, 1 pt. acid diacetonamine oxalate, and 12 pts. alcohol, gradually separating as a powder which may be purified by crystallisation from water. Colourless needles or monoclinic prisms (from ether). V. sol. alcohol and ether; sl. sol. water. Tasteless, has a faint aromatic odour. Forms normal and acid salts.—$C_{13}H_{17}NOHCl$. Crusts or druses of crystals.—$(C_{13}H_{17}NO.HCl)_2PtCl_4$. Warty groups of crystals, or when separated from alcohol on addition of ether, elongated six-sided tablets. Slightly soluble in hot, insol. in cold alcohol. The *aurochloride* forms pale-yellow crystals.—$C_{13}H_{17}NOHNO_3 + 2H_2O$ (?). Small crystals, moderately soluble in cold water.—$(C_{13}H_{17}NO)_2H_2SO_4$. Small crystals, easily soluble in water, very slightly in absolute alcohol.—$(C_{13}H_{17}NO)_2,C_2H_2O_4$. Microscopic crystals, nearly insoluble in alcohol, v. sl. sol. water (R. Schiff, *A.* 193, 62).

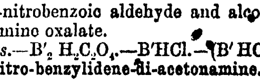
***m*-Amido-benzylidene-di-acetonamine**

$$\mathrm{NH_2.C_6H_4.CH}\begin{array}{l}\diagup\mathrm{CH_2 . CO}\diagdown\\ \diagdown\mathrm{NH.CMe_2}\diagup\end{array}\mathrm{CH_2}$$

From the nitro-derivative by reduction with $SnCl_2$. Oil. *Salts.*—$B''H_2C_2O_4$ [113°].

***p*-Amido-benzylidene-di-acetonamine.**—From the nitro-derivative by $SnCl_2$. *Salt.*—$B''H_2C_2O_4$.

***o*-Nitro-benzylidene-di-acetonamine**



$$\mathrm{NO_2.C_6H_4.CH}\begin{array}{l}\diagup\mathrm{CH_2 . CO}\diagdown\\ \diagdown\mathrm{NH.CMe_2}\diagup\end{array}\mathrm{CH_2}.$$

From *o*-nitrobenzoic aldehyde and alcoholic di-acetonamine oxalate.

Salts.—$B'_2 H_2C_2O_4$.—B'HCl.—$(B'HCl)_2PtCl_4$.

***m*-Nitro-benzylidene-di-acetonamine.**

Salts.—B'HCl [208°].—$(B'HCl)_2PtCl_4$ [203°].

***p*-Nitro-benzylidene-di-acetonamine** [142·5°]. Needles (from ether). Nearly insol. light petroleum.

Salts.—B'HCl aq. [c. 206°].—$(B'HCl)_2PtCl_4$.

p-Oxy-benzylidene-di-acetonamine

$HO.C_6H_4.CH\langle \frac{CH_2 . CO}{NH.CMe_2} \rangle CH_2$.

From di-acetonamine oxalate (5 pts.), *p*-oxy-benzoic aldehyde (4 pts.), and alcohol (20 pts.)

Acid oxalate $B'H_2C_2O_4$.

Methyl derivative

$MeO.C_6H_4.CH\langle \frac{CH_2 . CO}{NH.CMe_2} \rangle CH_2$.

From anisaldehyde and di-acetonamine oxalate.

Oxalate $B'_2H_2C_2O_4$ [210°].

Cinnamylidene-di-acetonamine

$Ph.CH:CH.CH\langle \frac{CH_2 . CO}{NH.CMe_2} \rangle CH_2$ ½ aq. [49°].

From cinnamic aldehyde, diacetonamine, and boiling alcohol. Yellow needles (from alcohol). Easily soluble in ether, light petroleum, chloroform and benzene, sparingly in water.

Vanillo-di-acetonamine $C_{14}H_{19}NO_3$ *i.e.*

$C_6H_3(OMe)(OH)CH\langle \frac{CH_2 . CO}{NH.CMe_2} \rangle CH_2$

is obtained by boiling equal parts of vanillin and acid diacetonamine oxalate-diacetonamine cohol, whereby normal This salt forms either oxalate is three or yellowish crystalline crusts; a white water, insol. alcohol and ether. The base is an alkaline oil, slightly soluble in water.—$C_{14}H_{19}NO_3HCl$ is easily soluble in alcohol, and precipitated therefrom by ether.—$(C_{14}H_{19}NO_3HCl)_2PtCl_4$.—$C_{14}H_{19}NO_3HNO_3$. Very small crystals, m. sol. water, and cold alcohol, $(C_{14}H_{19}NO_3)_2H_2SO_4$: laminæ. $(C_{14}H_{19}NO_3)_2C_2H_2O_4$: crystalline, v. sl. sol. water, insol. alcohol (Heintz, *A*. 194, 53).

ALKYL-DI-ACETONAMINES.

Methyl di-acetonamine

$C_7H_{15}NO$ *i.e.* $COMe.CH_2.CMe_2.NHMe$,

is formed, together with other bases, when acetone saturated with methylamine is left to itself for several weeks. The base is ppd. as acid oxalate, and purified by conversion into platinochloride.—Free methyldiacetonamine is very unstable, quickly splitting up into methylamine and mesityl oxide. The *hydrochloride* is deliquescent. The *platinochloride* $(C_7H_{15}NOHCl)_2PtCl_4$ crystallises in large light-red rhombic prisms, easily soluble in water, nearly insoluble in alcohol. The *platinosochloride* $(C_7H_{15}NOHCl)_2PtCl_2$, produced simultaneously with the platinochloride, forms dark red crystals. The *aurochloride* $C_7H_{15}NO,HCl,AuCl_3$, forms short prisms, m. sol. cold, v. sol. hot, water, alcohol, and ether. The *normal oxalate* $(C_7H_{15}NO)_2C_2H_2O_4$ forms indistinct very deliquescent crystals, very soluble in absolute alcohol; the *acid oxalate* $C_7H_{15}NOC_2H_2O_4$ crystallises in small prisms, m. sol. absolute alcohol. The *picrate* forms yellow needles (Götschmann, *A*. 197, 38).

Dimethyldiacetonamine

$C_8H_{17}NO$ *i.e.* $COMe.CH_2.CMe_2.NMe_2$,

is formed on heating a solution of dimethylamine in acetone at 100°-105° in a sealed tube. Free dimethyldiacetonamine has not been obtained as it very easily splits up into dimethylamine and mesityl oxide. The *platino-chloride* $(C_8H_{17}NOHCl)_2PtCl_4$ crystallises in small tablets; the *auro-chloride* in golden needles, sl. sol. water; the *nitrate* and *sulphate* in long colourless deliquescent needles v. sol. alcohol. The *acid oxalate*, $C_8H_{17}NOC_2H_2O_4$, is crystalline, v. sol. water and alcohol, nearly insoluble in ether (Götschmann, *A*. 197, 27).

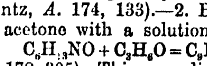
Ethyldiacetonamine

$C_8H_{17}NO$ *i.e.* $MeCO.CH_2.CMe_2.NHEt$,

is obtained by heating a solution of ethylamine in acetone at 80° for six hours. $C_{16}H_{36}N_2O_2PtCl_6$, light red hexagonal plates, insol. ether and alcohol, soluble in alcohol containing HCl. S. 1·16 at 16°. *Platinosochloride*: $C_{16}H_{36}N_2O_2PtCl_4$; dark red prisms. S. 6·62 at 21°, insoluble in ether and in alcohol.—$C_8H_{17}NOHCl$ forms hygroscopic microcrystals decomposing at 150°.—$C_8H_{18}NOAuCl_4$ crystallises in large lemon-yellow rhombic plates. S. 2·48 at 22°; easily soluble in alcohol and ether; melts under water at about 70°.—The *nitrate* forms small needles.—$(C_8H_{17}NO)_2H_2SO_4$ forms tufts of needles.—$(C_8H_{17}NO)_2C_2H_2O_4$, concentric groups of hygroscopic needles.—$C_8H_{17}NOC_2H_2O_4$; needles.—The *picrate* $C_8H_{17}NO,C_6H_2(NO_2)_3OH$ forms short needle-shaped prisms v. sol. water, insol. alcohol Free ethyldiacetonamine splits up even in the cold into ethylamine and mesityl oxide (Eppinger, *A*. 204, 50). The prolonged heating of ethylamine with acetone gives rise only to ethyl-diacetonamine, not to any base analogous to triacetonamine. Diethylamine does not appear to form any compound with acetone (Eppinger).

Dehydrodiacetonamine $C_6H_{11}N(?)$ contained in the mother-liquors of the preparation of acid diacetonamine oxalate, and passes over on distilling them with an alkali. The platinochloride forms slightly sol. laminæ (Heintz, *A*. 183, 276).

Triacetonamine $C_9H_{17}NO$ *i.e.*



$NH\langle \frac{CMe_2.CH_2}{CMe_2.CH_2} \rangle CO$

Oxy-tetra-methyl-tetra-hydro-pyridine [58°] (hydrated); [39·6°] (dry). *Formation.*—1. Together with diacetonamine, by the action of ammonia on acetone, especially at high temperatures (Heintz, *A*. 174, 133).—2. By prolonged boiling of acetone with a solution of diacetonamine: $C_6H_{13}NO + C_3H_6O = C_9H_{17}NO + H_2O$ (Heintz, *A*. 178, 305). This, according to Heintz, is the best mode of preparing triacetonamine. It is purified by crystallisation of the oxalate. Triacetonamine separates from a solution of the normal oxalate mixed with KOH, as a hydrate $C_9H_{17}NO,H_2O$, which crystallises from anhydrous ether in large square tablets, and the mother-liquor on further evaporation and cooling to a very low temperature yields long needle-shaped crystals of anhydrous triacetonamine. Hydrated crystals rhombic $a : b : c = 0·9586 : 0·9768 : 1$. Triacetonamine sublimes slowly, even at ord. temp. Distils without alteration. Decomposed at 150°-200° by H_2SO_4 or P_2O_5, but does not yield definite products. Heated at 100° for 16 hours with fuming hydrochloric acid it yields diacetonamine, dehydropentacetonamine and other products. With chromic acid mixture it gives isopropyl-butyl-amine di-carboxylic acid: $C_9H_{17}NO_4$ *i.e.* $CO_2H.CMe_2.NH.CMe_2.CH_2.CO_2H$ (Heintz, *A*. 198, 69). With ethyl iodide it yields NH_2Et, $NHEt_2$, NEt_3, NEt_4I, dehydrotriacetonamine, and other products, but no ethylated triacetonamines (Heintz, *A.* 201, 100).

Salts.—B′HCl is easily soluble in alcohol, and separates therefrom on addition of ether, in prisms.—(B′HCl)$_2$PtCl$_4$3H$_2$O crystallises from hot water in long, dark, gold-coloured needles, v. sl. sol. alcohol, insol. ether. By exposing the alcoholic solution to sunlight, or heating the aqueous solution for several hours, it is reduced to (B′HCl)$_2$PtCl$_2$2H$_2$O, which is much less soluble in water than the platino-chloride, and crystallises in dark red needles or rhombic prisms.—(C$_9$H$_{17}$NO)$_2$H$_2$SO$_4$: delicate needles or prisms v. sol. in water, insol. alcohol and ether.—C$_9$H$_{17}$NO,HNO$_3$: rhombic crystals—$a:b:c=1·2738:1:1·0251$.—(C$_9$H$_{17}$NO)$_2$H$_2$CrO$_4$. Small light yellow crystals converted into the acid salt by recrystallisation from hot water.—(C$_9$H$_{17}$NO)$_2$H$_2$Cr$_2$O$_7$. Orange-red prisms (Heintz, *A.* 198, 87).—(C$_9$H$_{17}$NO)$_2$C$_2$H$_2$O$_4$ forms long needles, v. sol. water, v. sl. sol. alcohol.—C$_9$H$_{17}$NO,C$_2$H$_2$O$_4$. Triclinic crystals, v. sol. water; resolved by boiling with alcohol or ether into the normal salt and oxalic acid (Heintz, *A.* 178, 326).

Triacetonamine Nitrosamine C$_9$H$_{16}$(NO)NO [73°], S.G. 1·14, is formed by heating aqueous triacetonamine hydrochloride with KNO$_2$ at 85°. Long needles (from alcohol). V. sol. alcohol and ether. Resolved by KOH into nitrogen, water, and phorone, also by prolonged boiling in aqueous solution. By heating with HCl or H$_2$SO$_4$, it is for the most part reconverted into triacetonamine (Heintz, *A.* 185, 1; 187, 233).

Tri-acetone-diamine

C$_9$H$_{20}$N$_2$O *i.e.* (NH$_2$.CMe$_2$.CH$_2$)$_2$CO.

Found in small quantity amongst the products of the action of ammonia on acetone; produced more abundantly when a mixture of 1 pt. acetone, 2 pts. NH$_3$Aq, and 1 pt. CS$_2$, is left at rest for a month; $3C_3H_6O + 2NH_3 = C_9H_{20}N_2O + 2H_2O$. Oily liquid soluble in water, somewhat sparingly in ether. B″2HCl forms prismatic crystals, decomposing at 200°.—B″2HCl,PtCl$_4$ is slightly soluble in cold, easily in hot water, insoluble in ether.—B″C$_2$H$_2$O$_4$; flat needles, nearly insoluble in alcohol, much more soluble in water, than the acid salt.—B″2H$_2$C$_2$O$_4$ aq; monoclinic prisms (Heintz, *A.* 203, 336).

Dehydro-tri-acetonamine C$_9$H$_{15}$N (*Tetra-methyl-di-hydro-pyridine?*) (158°) (H.); (163°) (C. S.).

Occurs as oxalate, together with tri-acetonamine, in the mother liquor got in preparing di-acetonamine oxalate (*q. v.*), and may be separated therefrom by distillation with potash (Heintz, *A.* 174, 166; 183, 276).

Preparation.—Acetone (20g.), acetamide (8g.), and ZnCl$_2$ (30g.), are heated for 6 hours at 140° (Canzeroni a. Spica, G. 14, 341). Another base (240°) is a by-product in this reaction. It appears to be C$_{15}$H$_{27}$N. Its platino-chloride forms dodecahedra.

Properties.—Oily liquid which readily oxidises, becoming brown.

Salts.—(B′HCl)$_2$PtCl$_4$. Rhombohedra (from water). V. sl. sol. cold water, insol. alcohol.—B′HAuCl$_4$ [127°]. Long yellow prisms (from dilute alcohol). Insol. water.

Dehydro-penta-acetonamine

$C_{15}H_{23}N = 5C_3H_6O + NH_3 - 5H_2O$.

Is formed together with ammonia and di-acetonamine by heating tri-acetonamine with fuming HCl at 130°, the hydrochloride then separating as a crystalline powder, sparingly soluble in water. The base separated therefrom by potash is an oily liquid (Heintz, *A.* 181, 70). H. W.

ACETO-NAPHTHYL-THIAMIDE *v.* *a*-NAPHTHYLAMINE.

ACETONE C$_3$H$_6$O *i.e.* CH$_3$.CO.CH$_3$.

Di-methyl Ketone.

M. w. 58 (55·6°–55·9° cor.) (Perkin, *C. J.* 45, 478); (56°) (Dumas; R. Schiff); (56·3°) at 760 mm. (Kopp, Regnault, Zander); (56·53° cor.) (Thorpe, *C. J.* 37, 212). S.G. ^{0} ·814; $^{13·9}$ ·799 (Kopp, *A.* 64, 214); $\frac{0}{4}$ ·8186 (T.); $\frac{15}{15}$ ·7965; $\frac{25}{25}$ ·7867 (P.); $\frac{0}{0}$ ·8125 (Z.); $\frac{20}{4}$ ·7920 (Brühl); $\frac{56}{4}$ ·7506 (R. Schiff, *A.* 220, 103). V.D. 2·00 (Dumas). C.E. (0°–10°) ·00138 (T.). S.V. 77·08 (S.); 77·3 (Z.); 76·78 (T.). H. F. p. 65,000 (Berthelot); 58,710 (Thomsen). H. F. v. 57,260 (Th.). μ_β 1·3639. R$_\infty$ 25·55 (Brühl). M. M. 3·514 at 15·2° (P.).—Occurs in the urine, blood, and brain of diabetics (Markownikoff, *B.* 8, 1683; Peters, Kaulich, Betz, *J.* 1861, 805).

Formation.—1. By the dry distillation of acetates: *e.g.* $(MeCO.O)_2Ba = Me_2CO + BaCO_3$.—2. From zinc-methyl and acetyl chloride;

(*a*) $MeCOCl + ZnMe_2 = MeCClMe.OZnMe$,
(*b*) $MeCClMe.OZnMe + H_2O =$
$Me_2CO + HCl + ZnO + CH_4$

(Freund, *A.* 118, 1).—3. By treating bromo- or chloro-propylene with aqueous hypochlorous acid and mercuric oxide, whereby chloracetone is formed:

$$2C_3H_5Cl + 2HOCl + HgO = HgCl_2 + H_2O + 2(CH_2Cl.CO.CH_3),$$

and reducing this compound to acetone with zinc and HCl (Linnemann, *Bl.* [2] 6, 216).—4. By treating the isomeric compound, propylene oxide, with sodium-amalgam, and dehydrogenising the resulting isopropyl alcohol with chromic mixture, $C_3H_6O + H_2 = (CH_3)_2CH.OH$, and

$$(CH_3)_2CH.OH + O = H_2O + (CH_3)_2CO$$

(Linnemann, *A.* 140, 178). Berthelot (*C. R.* 68, 334), effects the oxidation with aqueous chromic acid.—5. By the action of an aqueous solution of mercuric bromide (Kutscheroff, *B.* 14, 1541), or chloride (*B.* 17, 15), on allylene.—6. By passing aldehyde vapour over red-hot lime (Schloemilch, *Z.* 5, 336).—7. Together with propionic aldehyde, by heating a dilute aqueous solution of propylene glycol at 180°–190° (Eltekoff, *J.* 11, 409).—8. By heating propylene bromide with water at 170°–180°:

$$C_3H_6Br_2 + H_2O = 2HBr + C_3H_6O$$

(Linnemann, *A.* 161, 58).—9. By heating *a*-*a*-di-chloro-propane CMe$_2$Cl$_2$ with silver acetate and alcohol in sealed tubes at 100°:

$CMe_2Cl_2 + 2AgCO_2Me = 2AgCl + 2COMe_2 + CO_2$.—10. Together with a bromine compound (probably CHMe$_2$Br) by the action of zinc and dilute sulphuric acid on the product C$_3$H$_2$Cl$_2$Br$_2$O, formed by the action of bromine on dichlorhydrin (Lange, *B.* 6, 98).—11. By distilling with water the product formed, with evolution of HCl, on dissolving chloro-propylene Me.CCl:CH$_2$ in sulphuric acid (Oppenheim, *A.* Suppl. 6, 365).—12. Together with mesitylene, on distilling with water a solution of allylene in sulphuric acid (Schrohe, *B.* 8, 367).—13. Together with other products, by the action of lime on glycerin (Tawilderow, *B.* 12, 1487).—14. Together with isobutyric aldehyde, by oxidation of iso-butyl alcohol.—15. By oxidising with chromic acid the hexylene obtained by the action of alcoholic potash on di-methyl-isopropyl-carbinyl iodide (Pawlow, *Bl.* [2] 29, 375).—16. By the action of nascent zinc-methyl on acetic oxide (Saytzeff, *Z.* [2] 7, 104): $(COMe)_2O + ZnMe_2 = ZnO + 2COMe_2$.—17. Together with other products, by the action of zinc-sodium on a mixture of methyl iodide and acetic oxide (S.).—18. By the dry distillation of wood: occurs therefore in crude wood-spirit; also of sugar, gum, or starch, with 8 pts. lime (Fremy, *A. Ch.* 59, 7).—19. By dry distillation of citric acid, and in the oxidation of that acid by potassium permanganate, or by MnO_2 and dilute sulphuric acid (Péan de St. Gilles, *A. Ch.* [3] 55, 374).

Preparation.—1. By dry distillation of barium or calcium acetate. The barium salt decomposes at a moderate heat, and when dry and pure yields pure colourless acetone. The calcium salt requires a higher temperature and yields a distillate contaminated with an empyreumatic oil (dumasin) and other products.—2. By distilling in an iron retort or quicksilver bottle, a mixture of lead acetate (2 pts.) and quick lime (1 pt.), rectifying over calcium chloride, and finally distilling over the water-bath. The product may be purified from wood-spirit by distillation over calcium chloride, or better by combining the acetone with sodium hydrogen sulphite, and decomposing the resulting compound by an acid or alkali; also by converting the methyl alcohol into an ether (oxalic or benzoic). Crude acetone may also be purified by treating it with potassium permanganate, which does not attack pure acetone at ordinary temperatures.

Properties. — Limpid, very mobile liquid having a spirituous and slightly empyreumatic odour and biting taste. Very inflammable; burns with a white smokeless flame, mixes in all proportions with water, alcohol, and ether. Dissolves camphor, fats, and resins. Separated from aqueous solution by $CaCl_2$ and by KOH (difference from alcohol). Even if boiling between 56° and 58° it is liable to contain methyl-acetal, $CH_3.CH(OCH_3)_2$; this can be detected by heating with conc. HCl, for it then gives off MeCl. Acetone reacts with hydroxylamine and with phenyl-hydrazine (*v.* ACETOXIM, ACETONE PHENYL-HYDRAZIDE). It does not restore the
duced of a solution of a rosaniline salt that
forms dat·ached by SO_2 (Schiff).
$C_7H_{15}NO,HCl$.-1. An alcoholic liquid supposed
cold, v. sol. hot, is mixed with an equal volume
normal oxalate (C,... of benzoic aldehyde and
tinct very deliquescentH are added. After some
absolute alcohol; the *aci*di-benzylidene-acetone
crystallises in small prisolve in H_2SO_4 giving
alcohol. The *picrate* form. Ponder, *A.* 223,
(Götschmann, *A.* 197, 38). ueous KOH and
Dimethyldiacetonamine 3. A solution
$C_8H_{17}NO$ *i.e.* CO.Me.CH_2.CMe_2. previously
is formed on heating a solution of A black
mine in acetone at 100°-105° in a seaars, but
Free dimethyldiacetonamine has not des this
tained as it very easily splits up into dimve to
amine and mesityl oxide. The *platino-chlo* be
$(C_8H_{17}NOHCl)_2PtCl_4$ crystallises in small tables

Reactions.—1. Acetone-vapour passed through a *red-hot tube* deposits carbon and yields so-called dumasin, also naphthalene, CO_2, CH_4, and H (Barbieri a. Roux, *C.R.* 102, 1559).—2. By *nascent hydrogen* (sodium-amalgam and water) acetone is converted into isopropyl alcohol: $Me.CO.Me + H_2 = Me.CH(OH).Me$ (Friedel, *C.R.* 55, 53).—3. *Chlorine-gas* passed into acetone displaces 1 or 2 ats. H, forming C_3H_5ClO and $C_3H_4Cl_2O$, but does not remove the whole of the hydrogen, even in sunshine. Grabowski (*B.* 8, 1438), by passing chlorine into pure acetone, assisting the action by heat towards the end, obtained in addition to dichloracetone, two bodies $C_5H_7Cl_3O$ and $C_6H_7Cl_3O$. The former is a liquid insoluble in water (186°). S.G. 1·330 at 29°. V.D. 6·60 (calc. 6·56). Decomposed by strong potash-lye, with separation of chloroform. The second body, $C_6H_7Cl_3O$, is also liquid (206°–208°). S.G. 1·326 at 26°. V.D. 7·55 (calc. 7·0). Completely decomposed by strong potash-lye or sulphuric acid. Perhaps trichlorotrimesityloxide. When acetone is treated with excess of chlorine, and the product first with KOH and then with HCl, isapoglucic acid $C_9H_{10}O_5$ is produced. With alcoholic potash, on the other hand, a body $C_6H_{10}O_5$ (?) is formed, together with an acid whose lead-salt has the composition $Pb(C_7H_9O_3)_2$ (Mulder, *J.* 1868, 494).—4. *Chlorine*, in presence of alkalis, converts acetone into chloroform:

$$C_3H_6O + 6Cl_2 + H_2O = 2CHCl_3 + CO_2 + 6HCl.$$

Bromine acts in like manner, producing bromoform, and iodine forms iodoform.—5. When acetone saturated with HCl-gas is mixed, after 8–14 days, with *water*, a heavy brownish oil separates, consisting mainly of compounds of HCl with mesityl oxide, $C_6H_{10}O\ (=2C_3H_6O - H_2O)$ and phorone, $C_9H_{14}O(=3C_3H_6O - 2H_2O)$. The mesityl compound $C_6H_{12}OCl_2$, heated with KCN and then with KOH, yields the K-salt of a monobasic acid $C_8H_{13}NO_3$ (*v.* MESITONIC ACID), thus: $C_6H_{12}OCl_2 + 2KCN = 2KCl + C_6H_{12}O(CN)_2$; and $C_6H_{12}O(CN)_2 + KOH + H_2O = NH_3 + KC_8H_{12}NO_3$. The phorone compound, similarly treated, yields a neutral azotised body crystallising in shining plates and subliming at about 300° (Maxwell Simpson, *Pr.* 16, 364). According to Pinner (*B.* 14, 1070) the neutral body is a nitrile $C_{11}H_{18}O_2N_2$, formed according to the equation $3C_3H_6O + 2HCN = H_2O + C_{11}H_{18}O_2N_2$; it crystallises in plates melting above 320°. Heated with aqueous hydrochloric acid it gives phoronic acid $C_{11}H_{18}O_5$ [*q.v.*]: $C_9H_{18}O_2(CN)_2 + 4H_2O = 2NH_3 + H_2O + C_9H_{16}O(CO_2H)_2$.—6. By distillation with strong *sulphuric acid*, acetone yields mesitylene, $C_9H_{12} = 3C_3H_6O - 3H_2O$; but when mixed with H_2SO_4 in a cooled vessel it forms mesityl-sulphonic acid $C_3H_5.SO_3H$, which, when heated with potash, yields mesityl oxide (Hlasiwetz, *J.* 1856, 487).—7. With PCl_5 acetone yields chloropropylene C_3H_5Cl and di-chloro-propane $C_3H_6Cl_2$ (Friedel, *A.* 112, 236).—8. With *bromine* acetone unites directly, forming $C_3H_6OBr_2$, a viscid, very unstable liquid, heavier than water (Linnemann, *A.* 125, 307). According to E. J. Mulder, however (*J. pr.* 91, 47), it gives rise to substitution-products.—9. With HI acetone yields iodopropylene, C_3H_5I; with PI_3 a solid and two liquid iodides (Harnitz-Harnitzky, *Z.* 1863, 416). According to Berthelot (*Bl.* [2] 7, 69), acetone treated with HI yields propane.—

10. With *iodine chloride* acetone yields $C_3H_4I_2O$ (Maxwell Simpson, *Laboratory*, p. 79).—11. *Electrolysis* of a mixture of acetone and dilute sulphuric acid produces acetic, formic, and carbonic acids (Friedel, *J.* 1859, 338).—12. By *chromic acid* mixture it is oxidised to acetic and carbonic acids.—13. Acetone heated with *ammonia* yields a mixture of three bases, the composition and mode of formation of which are indicated by the following formulæ:—

Diacetonamine	$C_6H_{13}NO = 2C_3H_6O + NH_3 - H_2O$
Triacetonamine	$C_9H_{17}NO = 3C_3H_6O + NH_3 - 2H_2O$
Dehydrotriacetonamine	$C_9H_{15}N = C_9H_{17}NO - H_2O$.

With *methylamine*, in like manner, acetone yields methyldiacetonamine $C_7H_{15}NO$ and other bases. With *dimethylamine* only dimethyldiacetonamine $C_8H_{17}NO$.—14. With *hydroxylamine*, acetone forms ACETOXIM [*q.v.*] $Me_2C:NOH$, which crystallises in prisms [60°], (135°).—15. *Sodium* strongly attacks acetone, with formation of crystallised pinacone hydrate $C_6H_{12}O\ 7H_2O$ and liquid phorone $C_9H_{14}O$ thus: $2C_3H_6O + Na_2 = Na_2O + C_6H_{12}O$, and $3C_3H_6O - 2H_2O = C_9H_{14}O$ (Städeler, *A.* 111, 277).—16. Heated with *aniline hydrochloride* at 180° it forms di-methyl-quinoline (Engler a. Riehm, *B.* 18, 2245, 3296).—17. *Caustic alkalis*, *e.g.* KOH and CaO, exert a dehydrating action on acetone and form condensation-products varying in composition, according to the proportion of water abstracted, viz.:

		B. P.
Xylite-naphtha	$C_{12}H_{22}O_3 = 4C_3H_6O - H_2O$	110°–120°
Mesityl oxide	$C_6H_{10}O = 2C_3H_6O - H_2O$	131°
Mesitylene	$C_9H_{12} = 3C_3H_6O - 3H_2O$	155°–160°
Phorone	$C_9H_{14}O = 3C_3H_6O - 2H_2O$	216°–220°
Xylite-oil	$C_{12}H_{18}O = 4C_3H_6O - 3H_2O$	above 250°

Vapour of acetone passed over strongly heated KOH or potash-lime is resolved into methane and carbonic acid, $C_3H_6O + 2KOH = K_2CO_3 + 2CH_4$. At a lower temperature the chief products are acetic acid, formic acid, and hydrogen, $C_3H_6O + 2KOH + H_2O = KC_2H_3O_2 + KCHO_2 + 3H_2$ (Dumas a. Stas, *A. Ch.* [2] 73, 149; Persoz, *Rev. Scient.* 1, 51).—18. Acetone heated with $ZnCl_2$ yields hexa-methyl-benzene C_6Me_6 (W. H. Greene, *C. R.* 87, 931).—19. Gently heated with $AlCl_3$, it yields mesityl oxide, phorone, and other products (Louise, *C. R.* 95, 602).—20. Dry $PtCl_4$ dissolves in acetone, and the solution when evaporated leaves a brown resinous mass containing a yellow crystalline substance, $C_6H_{10}OPtCl_2$ (?), called *Acechloride of Platinum*, or *Chloroplatinite of Mesityl* (Zeise, *A.* 33, 29).—21. On adding HCl to a mixture of acetone, with potassium cyanide and sulphocyanide, the compound $C_5H_7O_2NS$ is obtained. This compound heated with HCl is resolved into CO_2, NH_3, and α-oxy-iso-butyric acid. With silver nitrate it yields $C_5H_6AgO_2NS$ (Urech, *B.* 6, 1113).—22. By action of alkalis or of HCl-gas on a mixture of 1 mol. acetone and 2 mol. benzaldehyde, DIBENZYLIDENE-ACETONE (*q. v.*) PhCH:CH.CO.CH:CHPh is obtained (Claison a. Claparede, *B.* 14, 349). By the action of alkalis on a solution of *o*-nitro-benzaldehyde in acetone, methyl *o*-nitro-β-oxy-β-phenyl-ethyl ketone [68°] is formed according to the equation

$$NO_2.C_6H_4.CHO + CO(CH_3)_2 = NO_2.C_6H_4.CH(OH).CH_2.COCH_3$$

(Baeyer a. Drewsen, *B.* 15, 2856).—The corresponding *para*-compound [58°] is obtained in like manner from acetone and *p*-nitro-benzaldehyde (Baeyer a. Becker, *B.* 16, 1968).—23. With *furfuraldehyde*, acetone forms a compound crystallising in long white needles [37°] (J. G. Schmidt, *B.* 14, 574)—*v.* FURFURYLIDENE-ACETONE. 24. With *pyrrol* in presence of HCl it forms $C_{14}H_{16}N_2$, [291°] (Baeyer, *B.* 19, 2184).

Combinations.—1. With **Bisulphites.** Formed by direct combination. $C_3H_6(OH)SO_3NH_4$ crystallises in laminæ (Städeler, *A.* 111, 307)—$C_3H_6(OH)SO_3Na$.—Laminæ, moderately soluble in water, less in alcohol. Gives off acetone when boiled with aqueous sodium carbonate (Limpricht, *A.* 93, 238)—$C_3H_6(OH)SO_3K$ (L.). 2. With **Mercuric Oxide** $2C_3H_6O\ 3HgO$. Formed by mixing acetone with mercuric chloride and weak potash-lye, dialysing the filtered liquid, and precipitating the liquid remaining in the dialyser with acetic acid.—Gelatinous precipitate which becomes resinous on drying. Its solution gelatinises when heated or when merely left at rest (Emerson Reynolds, *Pr.* 19, 431). Formed also by dissolving HgO in acetone (Kutscheroff, *B.* 17, 20).

Acetone-boric Acid, $C_3H_6O(BHO)_2$ [50°]. Formed together with (α) and (β) acetone-fluoboric acid, and hydrocarbons, on saturating acetone with boron fluoride and distilling the product. (α) *Acetonefluoboric acid*, $C_3H_6O\ 3HFB_4O_4$ (120°–123°); the isomeric (β) modification [36°] (90°–92°) forms shining white laminæ. All three compounds fume in the air, burn with green flame, and are quickly decomposed by water, yielding boric acid and acetone hydrofluoric acid (Landolf, *C. R.* 89, 173).

Acetone-hydrofluoric Acid C_3H_6OHF (55°) obtained by fractional distillation from the product of the action of water on acetone-fluoboric acid. An inflammable liquid with pleasant ethereal odour (Landolf, *C. R.* 96, 580). Another compound, $C_3H_6O\ 2HF$ (–12°) is gaseous at ordinary temperatures.

Acetone-sulphonic Acid $CH_3.CO.CH_2.SO_3H$. Formed as K-salt by treating dichloracetone (118°) with a strong solution of potassium sulphite:

$$C_3H_4Cl_2O + K_2SO_3 + H_2O = K_2SO_4 + HCl + C_3H_5ClO, \text{ and}$$
$$C_3H_5ClO + K_2SO_3 = KCl + C_3H_5O.SO_3K.$$

The K-salt may be extracted from the product by boiling alcohol, and separates therefrom in white laminæ. Very soluble in water, not decomposed by boiling with dilute acids. Boiled with strong potash-lye, it yields sulphite and perhaps an acetone-alcohol (Bender, *Z.* 1870, 162; *B.* 4, 517). *Salts.*—KA′ Plates (from alcohol V. e. sol. water—BaA′$_2$ aq. Plates.—PbA′$_2$ aq. [140°]—CuA′$_2$ 1⅓aq. Greenish plates.

Acetone-phosphorous Acid $C_3H_6O.PO_2H$. Remains on distilling acetone with I and P. $(C_3H_6O.PO_2)_2Ba$ is amorphous, soluble in water, insoluble in alcohol (Mulder, *J.*, 1864, 329).

Acetone-cyanhydrin $CH_3.C(CN)(OH).CH_3$ (*Oxyisobutyronitrile*). Formed by the action of aqueous HCN (20 p.c.) on acetone, or by the action of nascent HCN on acetone diluted with ether.

It is very unstable, for even on evaporation of its solution it changes into di-acetone-cyanhydrin with evolution of HCN (Tiemann a. Friedländer, *B.* 14, 1970). Alcoholic NH_3 at 60° converts it into α-amido-iso-butyronitrile $CH_3.C(CN)(NH_2).CH_3$ whence HCl forms α-amido-iso-butyric acid. Alcoholic HCl forms the imido-ether $Me_2C(OH)C(OEt):NH$ (Pinner, *B.* 17, 2009).

Diacetone cyanhydrin $CMe_2(CN).O.CMe_2(OH)$, is prepared by adding 1 mol. HCl (gaseous or aqueous) to 1 mol. KCN immersed in acetone, dissolving the product in ether, and evaporating (Urech, *A.* 164, 259). Thick shining anhydrous prisms, easily soluble in water, alcohol, and ether. Melts at 135°–152° and sublimes below its melting point in long needles. Decomposed at ord. temp. by HCl into N acetone, and α-oxy-iso-butyric acid.

Substitution Products v. Chloro-acetone, Chloro-bromo-a acetone, Cyano-acetone, Thio-aceto.

Meta-acetone. — This name was Fremy (*A. Ch.* [2] 59, 6) to an oil o among the products of the distillation of starch, or gum, with quicklime. He ascribe it the formula $C_6H_{10}O$ and boiling-point 84°. Gottlieb (*A.* 52, 128) converted it by chromic mixture into propionic acid (called therefore Metacetonic acid). Benedikt (*A.* 162, 303) found V.D. 3·53 instead of 3·59, and stated that it did not combine with $NaHSO_3$. Meta-acetone has also been examined by Favre (*A. Ch.* [3] 11, 80), Cahours (*C. R.* 30, 319), who describes it as present in crude wood spirit, Lies-Bodart (*J.* 1856, 455), and Schwartz (*J.* 1850, 533). Nevertheless Pinner (*B.* 15, 586; 16, 1729) considers metacetone to be a very complicated mixture. H. W.

Para-acetone *v.* Pinacone.

ACETONE-ALCAMINES. — These are products derived from the acetonamines by reduction, their CO being converted into CH(OH).

Diacetone-alcamine $C_6H_{15}NO$ *i.e.* $NH_2.CMe_2.CH_2.CH(OH).Me$ (175°). Formed by reduction of diacetonamine by gradually adding sodium-amalgam to its solution in alcohol diluted with aqueous ammonia. Liquid, having a faint ammoniacal odour, miscible in all proportions with water. Absorbs CO_2 from the air; fumes with HCl. $(C_6H_{15}NOHCl)_2PtCl_4$ forms orange-red triclinic crystals, easily soluble in hot water.

Ethylidene-diacetone-alcamine

$C_8H_{17}NO$ *i.e.*

$$\begin{array}{ccc} H_2C - CH(OH) - CH_2 \\ | \qquad\qquad\qquad | \\ MeHC - NH - CMe_2 \end{array}$$

Oxy-tri-methyl-hexa-hydro-pyridine [123°]. Colourless crystalline solid. Easily soluble in
water and alcohol, sparingly in ether, and ben-
forms. Formed by reduction of ethylidene-
$C_7H_{15}NO$, Hine with sodium-amalgam in slightly
cold, v. sol. hot, solution. The hydro-chloride
normal oxalate (C dles, the sulphate large flat
tinct very deliquescen 7, 1794).
absolute alcohol; the acid $C_8H_{19}NO$
crystallises in small pris I)—CH_2
alcohol. The *picrate* form [128·5°]
(Götschmann, *A.* 197, 38). ue Me_2

Dimethyldiacetonamine ine. Formed
$C_8H_{17}NO$ *i.e.* $CO.Me.CH_2.CMe_2$ pr by reduc-
is formed on heating a solution of algam in
mine in acetone at 100°–105° in a se ars, *B.* 17
Free dimethyldiacetonamine has not this
tained as it very easily splits up into di e to
amine and mesityl oxide. The *platino-chl* be
$(C_8H_{17}NOHCl)_2PtCl_4$ crystallises in small table

forms rhombic crystals (Heintz, *A.* 183, 200, 317).

Methyl-tri-acetone-alcamine $C_{10}H_{21}NO$ [74°] or, when hydrated, [60°]. Formed from tri-acetone-alcamine by MeI and MeOH at 100° (E. Fischer, *B.* 16, 1605). Slender plates (from water). Strongly alkaline. H. W.

ACETONE ALCOHOL *v.* Acetyl-carbinol.

ACETONE-AMMONIA *v.* Acetonamines.

ACETONE-BENZIL $C_{17}H_{16}O_3$ *i.e.*
$Ph.CO.CPh(OH).CH_2.CO.CH_3$ [78°].

Preparation.—Benzil is shaken with excess of pure acetone and a little conc. KOH, and the crystals obtained are dissolved in ether (free from alcohol), which is allowed to evaporate. $C_{14}H_{10}O_2 + C_3H_6O = C_{17}H_{16}O_3$ (Japp a. Miller, *C.* 47, 21).

Properties.—Colourless square prisms. Sol. ether or alcohol. Resolved by heat into its constituents.

Reactions.—1. *Chromic mixture* gives benzoic and acetic acids.—2. Dry NH_3 gives *acetone-benzilimide* (*q. v.*).—3. Alcoholic *hydroxylamine* gives $C_{17}H_{16}O_2(NOH)$, [146°]; m. sol. benzene, sl. sol. ether. This body is not affected by further treatment with hydroxylamine.

Dehydro-acetone-benzil $C_{17}H_{14}O_2$ *i.e.*

$$Ph.CO.CPh\!\left<\begin{matrix}CH_2\\CH_2\end{matrix}\right>\!CO \quad [149°].$$

Preparation.—Benzil is shaken with excess of pure acetone and excess of conc. KOH (J. a. M.) $C_{14}H_{10}O_2 + C_3H_6O = C_{17}H_{14}O_2 + H_2O$.

Properties.—Colourless prisms.

Reactions.—1. Converted by *bromine* in chloroform to a bromo derivative, $C_{17}H_{13}BrO_2$ [172°]; slender needles (from glacial HOAc).—2. *Chromic acid* in glacial HOAc forms an acid, $C_{16}H_{14}O_3$, [152°]; needles. Salts, AgA'—BaA'$_2$ 2aq.

Dehydro-acetone-di-benzil $C_{31}H_{24}O_4$ [195°].

Formation.—1. From acetone-benzil and dilute alcoholic KOH.—2. From acetone, excess of benzil, and a little conc. KOH.

$$2C_{14}H_{10}O_2 + C_3H_6O = C_{31}H_{24}O_4 + H_2O.$$

Properties.—Colourless crystals (from benzene); sl. sol. boiling alcohol. Crystallises from alcohol with one molecule EtOH.

ACETONE-BENZILIMIDE $C_{17}H_{17}NO_2$ [176°]. From acetone-benzil and dry NH_3. Flat plates (from alcohol). Heated with HCl and oxalic acid, gives a red gum (J. a. M.).

ACETONE-BORIC ACID *v.* Acetone.

ACETONE-BROMIDE = di-Bromo-propane (*q. v.*).

ACETONE-BROMOFORM $C_4H_7OBr_3$ *i.e.* $Me_2C(OH).CBr_3$ [175°], or, when hydrated [167°]. From bromoform (5g.), acetone (30g.), and soda-lime (8g.) (Willgerodt a. A. Müller, *C. C.* 1884, 808).

ACETONE CARBOXYLIC ACID = Aceto-acetic acid (*q. v.*).

Acetone di-carboxylic acid $C_5H_6O_5$ *i.e.* $CO_2H.CH_2.CO.CH_2CO_2H$ [c. 130°]. Formed by heating citric acid with H_2SO_4. Colourless needles. Split up into CO_2 and acetone by heat, by boiling water, or by warm acids or alkalis. It contains methylenic hydrogen displaceable by Na. Fe_2Cl_6 gives a violet colour. It reacts with phenyl-hydrazine (Pechmann, *B.* 17, 2542). It forms a compound with HCN, which on saponification produces citric acid.

$NaNO_2$ converts it into di-oximido-acetone (Pechmann a. Wehsarg, *B.* 19, 2465).

The ***ethyl ether*** is an oil which can give rise to salts by exchanging its methylenic hydrogen for sodium or copper. *Reactions.*—1. By successive treatment with sodium and an alkyl iodide (RI) the following ethers may be got: $CO_2Et.CH_2.CO.CHR.CO_2Et$,

$CO_2Et.CHR.CO.CHR.CO_2Et$,

$CO_2Et.CHR.CO,CR_2.CO_2Et$,

and finally $CO_2Et.CR_2.CO.CR_2.CO_2Et$.

The acids obtained by saponifying these bodies are split up by heat into CO_2 and alkyl-acetones (Dünschmann a. v. Pechmann, *B.* 18, 2289).—2. Acetone di-carboxylic ether (100 g.) is converted by heating with Na (21 g.) into di-oxy-phenyl-acetic di-carboxylic ether

$$C_6H(OH)_2(CO_2Et)_2.CH_2.CO_2Et$$

(Cornelius a. Pechmann, *B.* 19, 1446).—3. Ammonia produces β-oxy-β-amido-glutaramic ether, $CO_2Et.CH_2.C(OH)(NH_2).CH_2.CO.NH_2$ [86°] (v. Pechmann a. Stokes, *B.* 18, 2290; 19, 2694).

ACETONE CHLORIDE *v. di*-CHLORO-PROPANE.

ACETONE CHLOROFORM $C_4H_7OCl_3$ *i.e.* $Me_2C(OH).CCl_3$. *Oxy-iso-butyro-tri-chloride.* [96°] or when hydrated, + ½aq, [81°] (167° uncor.).

Prepared by adding solid KOH to a cold mixture of acetone and chloroform. It is a crystalline solid, resembling camphor in appearance and smell. Rotates on water. V. sol. alcohol, ether, chloroform, acetone, or glacial HOAc, insol. water. Volatile with steam. Converted by water at 180° into α-oxy-iso-butyric acid (Willgerodt, *B.* 14, 2451; 15, 2305; 16, 1585).

ACETONE CYANHYDRIN *v.* ACETONE.

ACETONE-HYDROQUINONE $C_9H_{12}O_3$. From acetone and hydroquinone (Habermann, *M.* 5, 329).

ACETONE HYDROXYLAMIDE *v.* ACETOXIM.

ACETONE-PHENANTHRAQUINONE $C_{17}H_{14}O_3$ [90°].

Formation.—From phenanthraquinone by heating with a large excess of acetone at 200°. The product is washed with $NaHSO_3$ and extracted with ether (Japp a. Streatfeild, *C. J.* 41, 274).

Preparation.—Phenanthraquinone (50 g.) is shaken in a glass with acetone (60 g.) and conc. NH_3Aq (40 c.c.). Acetone-phenanthraquinonimide is formed and filtered off; after washing with ether, it is made into a cream with water and stirred into a solution of oxalic acid (90 g.) in water (800 c.c.) at 25°. The substance dissolves, but minute needles of acetone-phenanthraquinone soon separate (Japp a. Miller, *C. J.* 47, 18).

Properties.—Large thin blades (from ether). Insol. water, v. sol. ether, acetone or alcohol.

Reactions.—1. By *heat*, by *boiling water*, or by *boiling alcohol*, it is resolved into acetone and phenanthraquinone: $C_{17}H_{14}O_3 = C_{14}H_8O_2 + C_3H_6O$. 2. *Zinc dust* and glacial HOAc form $C_{17}H_{12}O$, [121°]. This is extracted by ether and crystallised from alcohol. It forms long slender needles, v. e. sol. ether or chloroform, v. sol. boiling alcohol, v. sl. sol. cold alcohol. Sublimes in feathery crystals. It decolorises bromine.—3. A few drops of dilute aqueous KOH added to an alcoholic solution forms minute crystals of acetone-di-phenanthraquinone (*q. v.*).—4. Conc. KOH (S.G. 1·27) added to a solution of acetone-phenanthraquinone in acetone forms a crystalline mass of di-acetone-phenanthraquinone.—5. *Ammonia* passed into an ethereal solution of acetone-phenanthraquinone forms crystals of acetone-phenanthraquinonimide.

Acetone-di-phenanthraquinone $C_{31}H_{22}O_5$ [190°]. Formed by adding a little dilute KOH to an alcoholic solution of acetone-phenanthraquinone (J. a. M.): $2C_{17}H_{14}O_3 = C_{31}H_{22}O_5 + C_3H_6O$. Colourless crystals (from benzene).

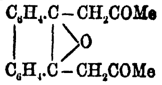
Di-acetone-phenanthraquinone $C_{20}H_{20}O_4$ [187°].

Preparation.—Pure acetone (43 g.) is shaken with finely powdered phenanthraquinone (50 g.) and a little (2 c.c.) conc. KOHAq (S.G. 1·27). After 12 hrs. the resulting solid cake is washed with ether and crystallised from acetone (J. a. M.).

Properties.—Short oblique prisms. Sparingly soluble in the usual menstrua. Sol. acetone or benzene. Decomposed by boiling glacial HOAc or amyl alcohol. Decomposed on melting into acetone and phenanthraquinone.

Reactions.—Boiling Ac_2O converts it into dehydro-di-acetone-phenanthraquinone.

Dehydro-di-acetone-phenanthraquinone $C_{20}H_{18}O_3$ [179°-181°]. Colourless pointed prisms (from benzene). Formed as above. Its constitution is perhaps:



$$\begin{array}{l} C_6H_4.C-CH_2COMe \\ \;\;| \qquad\;\; |\rangle O \\ C_6H_4.C-CH_2COMe \end{array}$$

Dehydro-acetone-phenanthraquinone $C_{17}H_{12}O_2$ [195°]. Formed in small quantity, together with di-acetone-phenanthraquinone when excess of KOHAq (S.G. 1·27) acts upon a mixture of acetone and phenanthraquinone. It is present in the ethereal washings of the di-acetone-phenanthraquinone (J. a. M.).

Groups of minute needles (from benzene): m. sol. hot benzene, hot alcohol, or ether.

Acetone-phenanthraquinonimide $C_{17}H_{15}NO_2$ [130°]. *Formation.*—By passing NH_3 into an ethereal solution of acetone-phenanthraquinone.

Preparation.—Phenanthraquinone (50 g.), acetone (60 g.), and conc. NH_3Aq (40 c.c.), shaken together form a white crystalline powder which is washed with ether and crystallised from acetone containing a little NH_3Aq:

$$C_{14}H_8O_2 + C_3H_6O + NH_3 = C_{17}H_{15}NO_2 + H_2O$$

(J. a. S.). Colourless rhomboidal laminæ.

Reactions.—1. Ac_2O decomposes it, forming phenanthraquinone.—2. Cold conc. HCl dissolves it, but the solution soon deposits a dark blue substance. The diluted filtrate deposits colourless needles of acetone-phenanthraquinone:

$$C_{17}H_{15}NO_2 + H_2O = C_{17}H_{14}O_3 + NH_3$$

By using conc. aqueous oxalic acid as a solvent the formation of the blue compound may be avoided, and after dilution, the needles separate as before.

The following constitutional formulæ are suggested by Japp and Miller to explain the properties of the preceding bodies:

$$\begin{array}{l} C_6H_4.C(OH).CH_2.CO.Me \\ C_6H_4.CO \end{array}$$

for $C_{17}H_{14}O_3$

$$\begin{array}{l} C_6H_4.C(OH).CH_2.CO.Me \\ C_6H_4.C.NH \end{array}$$

for $C_{17}H_{15}NO_2$

$$\begin{array}{l} C_6H_4.C(OH).CH_2.CO.Me \\ C_6H_4.C(OH).CH_2.CO.Me \end{array}$$

for $C_{20}H_{20}O_4$

ACETONE-PHENYL-HYDRAZIDE: $(CH_3)_2C:N.NHPh$ (165°) at 91 mm. Oil. Prepared by mixing acetone with phenyl-hydrazine. It dissolves in cold aqueous acids and on warming the solution it is resolved into its constituents (Reisenegger, *B.* 16, 662).

DI-ACETONE-PHOSPHINIC ACID $C_6H_{13}PO_4$ aq, *i.e.* $(CH_3)_2CH.CHAc.PO(OH)_2$ aq, or, less probably $(CH_3.CO.CH_2)_2PH(OH)_2$aq. *Di-acetonyl-phosphinic acid, iso-propyl-acetonyl-phosphonic acid, ω-acetyl-iso-butane ω-phosphonic acid* [64°]. Formed by the action of water upon di-acetone-phosphorous chloride (*infra*). (Michaelis, *B.* 17, 1273; 18, 902):

$$C_6H_{10}O_2PCl + 2H_2O = C_6H_{13}PO_4 + HCl.$$

Slender needles. V. e. sol. water or alcohol, v. sol. ether. Strong dibasic acid.

Salts.—NH_4HA''. V. sol. water, sl. sol. alcohol. Crystals.—$(NH_4)_3HA''_2$ 2aq. Insol. alcohol.—$BaH_2A''_2$ 2aq. Needles; v. sol. water, sl. sol. alcohol.—BaA'' 6aq; m. sol. hot water; trimetric tables, $a : b : c = {\cdot}785 : 1 : 2{\cdot}525$.—$PbA''$.—$PbA''\ \frac{1}{2}\ PbO$.—$MgA''$ 6aq; ppd. by alcohol from aqueous solution in glittering plates.—KHA''; deliquescent gum: v. sol. alcohol.—$KH_3A''_2$; slender needles, v. sol. water, sl. sol. alcohol.—Ag_2A''.

Reactions.—1. HNO_3 forms a tribasic crystalline acid $C_4H_9PO_5$, possibly β-carboxy-propane-phosphonic acid: $CH_3.CH(CO_2H).CH_2.PO(OH)_2$. The salts Ag_3A''', and $Ba_3A'''_2$, are crystalline.

Oxim.—$C_6H_{16}(NOH)PO_3$ [170°]. Colourless crystals; v. sol. water or alcohol; dibasic acid.

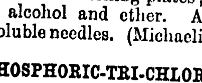
Di-Acetone-phenyl-phosphinic Acid $C_6H_{12}(C_6H_5)PO_3$, probably $(CH_3)_2CH.CH(CO.CH_3).PO(C_6H_5)OH$. [86°]. Prepared by adding P_2O_5 to a mixture of acetone and phosphenyl chloride, and treating the product with water:

$$(1)\ 2C_3H_6O + C_6H_5PCl_2 - H_2O = C_6H_{10}(C_6H_5)POCl_2$$
$$(2)\ C_6H_{10}(C_6H_5)POCl_2 + 2H_2O = C_6H_{12}(C_6H_5)PO_3 + 2HCl.$$

Long colourless plates ($+H_2O$). Sol. hot water, sl. sol. cold water and ether, v. e. sol. alcohol. The anhydrous acid forms a glassy mass, v. sol. ether. A′Ag; crystals, v. sol. water. (Michaelis, *B.* 19, 1009.)

Di-Acetone-*p*-tolyl-phosphinic Acid $C_6H_{12}(C_7H_7)PO_3$, probably $(CH_3)_2CH.CH(CO.CH_3).PO(C_7H_7)OH$. [103°]. Obtained by adding P_2O_5 to a mixture of acetone and *p*-tolyl-phosphorous chloride, and treating the product with water. Glistening plates; sol. hot water, v. sol. alcohol and ether. A′Ag; slender glistening soluble needles. (Michaelis, *B.* 19, 1012.)

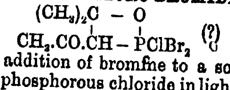
DI-ACETONE-PHOSPHORIC-TRI-CHLORIDE $C_6H_{10}O_2PCl_3$ *i.e.*



$$\begin{array}{c} (CH_3)_2{:}C - O \\ \qquad | \qquad\ | \\ CH_3.CO.CH - PCl_3 \end{array} \quad (?)$$

[115°]. Formed by passing chlorine into a solution of di-acetone-phosphorous chloride in petroleum-ether (Michaelis, *B.* 18, 901). Colourless crystals; sl. sol. petroleum-ether.

DI-ACETONE-PHOSPHORIC-CHLORO-BROMIDE $C_6H_{10}O_2PClBr_2$ *i.e.*



$$\begin{array}{c} (CH_3)_2C - O \\ \qquad | \qquad\ | \\ CH_3.CO.CH - PClBr_2 \end{array} \quad (?)$$

[142°]. Formed by addition of bromine to a solution of di-acetone-phosphorous chloride in light petroleum (Michaelis, *B.* 18, 900). Colourless crystals. Sl. sol. light petroleum. It is decomposed by water into mesityl oxide, phosphoric acid, HCl, and HBr.

ACETONE-PHOSPHOROUS ACID *v.* ACETONE.

DI-ACETONE-PHOSPHOROUS CHLORIDE $C_6H_{10}O_2PCl$ *i.e.*

$$\begin{array}{c} (CH_3)_2C - O \\ \qquad | \qquad | \\ CH_3.CO.CH.PCl \end{array} \quad (?)$$

[36°]. (154°) at 100 mm.; (235°) at 745 mm. S.G. (liquid) $\frac{17}{17}$ 1·209. Prepared by slowly adding Al_2Cl_6 (8 pts.) to a cooled mixture of PCl_3 (50 pts.) and 2½ times its volume of acetone; yield: 5 pts. It is decomposed by water into di-acetone-phosphinic acid $C_6H_{13}PO_4$ and HCl. It readily combines with 1 mol. of chlorine or bromine (Michaelis, *B.* 17, 1273; 18, 898).

ACETONE SULPHONIC ACID *v.* ACETONE.

ACETONIC ACID *v.* α-OXY-ISO-BUTYRIC ACID.

DI-ACETONIC ALCOHOL *v.* ACETYL-BUTYL ALCOHOL.

ACETONINE $C_9H_{18}N_2$. This base described by Städeler (*A.* 111, 277), Hlasiwetz (*A.* 76, 294), and Mulder (*A.* 168, 228), was found by Heintz (*A.* 201, 102) to be a mixture of di-acetonamine, tri-acetonamine, and tri-acetone-di-amine.

ACETONINES. Bases obtained by dehydrating acetone-alcamines by conc. H_2SO_4.

Ethylidene-di-acetonine $C_8H_{15}N$ *i.e.*

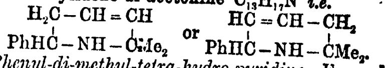
$$\begin{array}{c} CH{:}CH.CH_2 \\ |\qquad\quad | \\ MeCH.NH.CMe_2 \end{array} \quad \text{or} \quad \begin{array}{c} CH_2CH{:}CH \\ | \\ MeCH.NH.CMe_2 \end{array}$$

Tri-methyl-tetra-hydro-pyridine. (132°–137°.) Formed from ethylidene-di-acetone-alcamine (1 pt.) and conc. H_2SO_4 (3 pts.) by heating for 1½ hours at 100°.

Colourless oil with alkaline reaction. Volatile with steam. Sl. sol. water, more soluble in cold than in hot water. Miscible with alcohol, ether, or chloroform. Heated with HI, it yields iodo-tri-methyl-piperidine, $C_5H_7Me_3IN$ [60°].

Salts.—B′HI; slender, sparingly soluble needles.—B′HBr; small soluble trimetric pyramids (Fischer, *B.* 17, 1795).

Benzylidene-di-acetonine $C_{13}H_{17}N$ *i.e.*



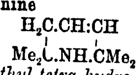
$$\begin{array}{c} H_2C - CH = CH \\ |\qquad\qquad\ \ | \\ PhHC - NH - CMe_2 \end{array} \quad \text{or} \quad \begin{array}{c} HC = CH - CH_2 \\ |\qquad\qquad\quad | \\ PhHC - NH - CMe_2. \end{array}$$

Phenyl-di-methyl-tetra-hydro-pyridine. Formed by the action of strong H_2SO_4 on benzylidene-di-acetone-alcamine.

Distils undecomposed. Volatile with steam. V. sol. alcohol or ether, v. sl. sol. water.

Salts.—*B′HBr: colourless tables or needles, sl. sol. cold water.—B′HI; sparingly soluble needles.—*B′HAuCl₄. (Fischer, *B.* 17, 1797.)

Tri-acetonine $C_9H_{17}N$ *i.e.*



$$\begin{array}{c} H_2C.CH{:}CH \\ |\qquad\ \ | \\ Me_2C.NH.CMe_2 \end{array}$$

(146°) at 740 mm.

Tetra-methyl-tetra-hydro-pyridine.

Prepared by heating tri-acetone-alcamine (1 pt.) with strong H_2SO_4 (3 pts.) on a water-bath for an hour, pouring into water, neutralising the acid, and distilling the base over with steam (Fischer, *B.* 16, 1604).

Properties.—Mobile fluid, smelling like piperidine. It combines with water forming a hydrate crystallising in long white needles, which give off their water at a moderate temperature. Volatile with steam. Poisonous. By heating with HI it gives iodo-tetra-methyl-piperidine.

Salts.—B′HBr; large white prisms, sl. sol. cold water.—B′HCl; v. sol. water or alcohol.—B′HAuCl₄; yellow needles.

Nitrosamine $C_9H_{16}N(NO)$: yellowish tables; v. sol. alcohol, ether, and benzene, nearly insoluble in water; volatile with steam; strong camphor-like smell.

Methyl derivative $C_9H_{16}NMe$: colourless oil very volatile with steam, sparingly soluble in water (Fischer, *B.* 17, 1789).

ACETO-NITRANILIDE *v.* NITRO-ANILINE.

ACETONITRILE C_2H_3N *i.e.* $CH_3.C{:}N$. *Methyl cyanide, methyl isocyanide.* M.w. 41. (81·6°) at 760 mm. (Vincent a. Delachanal, *Bl.* 33, 405); (81·3°) (R. Schiff, *B.* 19, 567). S. G. $\frac{0}{}$ ·805; $\frac{15}{}$ ·789 (V. a. D.). S.V. 57·23 (S.). H.F.p. –15,680. H.F.v. –16,260 (Thomsen). μ_D 1·3458 (V. a. D.). R_∞ 18·00 (Kanonnikoff, *J. pr.* [2] 31, 361). V.D. 1·45 (for 1·42).

Occurrence.—In crude benzene (V. a. D.).

Formation.—1. Dry $KMeSO_4$ is distilled with dry KCN and the distillate rectified over $CaCl_2$ (Frankland a. Kolbe, *C. S. Mem.* 3, 386; *A.* 65, 288).—2. From Me_2SO_4 and KCN, the product being distilled over HgO and then over P_2O_5 (Dumas, Malaguti a. Leblanc, *C. R.* 25, 474).—3. By distilling NH_4OAc with P_2O_5 (Dumas, *C. R.* 35, 383).—4. By distilling acetamide with P_2O_5 (Buckton a. Hofmann, *C. J.* 9, 242).—5. By distilling acetamide (5 mols.) with P_2S_5 (1 mol.), washing the product with NaOHAq and digesting with PbO (Henry, *A.* 152, 149).—6. From acetamide by action of PCl_5 (Wallach, *A.* 184, 21).

Preparation.—1. By boiling acetamide (500 g.) for a week with a little glacial acetic acid, the water produced being constantly allowed to distil off. The theoretical yield is got (Demarçay, *Bl.* [2] 33, 456).

Properties.—Colourless liquid with a pleasant ethereal odour; burns with a reddish-bordered flame. Miscible with water, but separated by salts from the solution. Mixes with alcohol. The presence of a little alcohol lowers its boiling-point several degrees (D.).

Reactions.—1. Hot aqueous KOH acts thus:

$$CH_3.CN + H_2O + KOH = CH_3CO_2K + NH_3.$$

2. *Chromic* and *nitric* acids have no action.—3. Heated with Na, it forms CYANMETHINE (*q.v.*) and NaCN.—4. Glacial HOAc at 200° forms di-acetamide: $CH_3CN + CH_3.CO.OH = (CH_3.CO)_2NH$ (Gautier, *A.* 150, 189).—5. Ac_2O, forms tri-acetamide: $CH_3.CN + (CH_3.CO)_2O = (CH_3.CO)_3N$. 6. Combines with dry HBr, HI, and (with difficulty) with HCl (Gautier, *A.* 142, 291).—7. *Bromine* forms the hydrobromide of the nitrile of BROMO-ACETIC ACID (*q.v.*), $CH_2Br.CH{:}NBr$ [65°].

Combinations.—C_2H_3N2HBr, or $CH_3.CH_2.NBr_2$ [47°–50°] crystals; may be sublimed.—$C_2H_3NPCl_5$ (72°): dissociated above its boiling point (Hencke, *A.* 106, 281).—$C_2H_3NSbCl_5$, formed with great rise of temperature; white crystals which may be sublimed (H.).—$C_2H_3NAuCl_3$: brownish-yellow powder (H.).—$(C_2H_3N)_2TiCl_4$: white crystalline crusts; may be sublimed (H.).—$(C_2H_3N)_2SnCl_4$: sublimes in arborescent formations (H.).—$C_2H_3N2Hg(CN)_2$: white vitreous mass; decomposes even over H_2SO_4 (Hesse, *A.* 110, 202), $CH_3.C(NH_2){:}NOH$, formed by the union of acetonitrile with hydroxylamine *v.* ETHENYL-AMID-OXIM.

ACETONURAMIC ACID $C_5H_{10}N_2O_3$ *i.e.* $NH_2.CO.NH.CMe_2.COOH$. *a-Uramido-iso-butyric acid, di-methyl-hydantoic acid.* Obtained, as barium salt $(C_5H_9N_2O_3)_2Ba(OH)_2$, by prolonged boiling of a solution of di-methyl-hydantoïn with baryta-water. The acid itself appears to be very unstable (Urech, *A.* 164, 255). A more stable acid of the same composition is obtained by evaporating the mixed solutions of the sulphate of amido-isobutyric acid and potassium cyanate. It forms crystals, melting, with loss of water, at 160°, moderately soluble in hot water and alcohol. Decomposed by prolonged heating at 130°–140° into water and di-methyl-hydantoin. $C_5H_9AgN_2O_3$ crystallises in needles (Urech, *A.* 164, 274). H. W.

ACETONYL-ACETO-ACETIC ETHER $C_9H_{14}O_4$, *i.e.* $CH_3.CO.CH_2.CHAc.CO_2Et$, *a-β-di-acetyl propionic ether.*

From aceto-acetic ether and chloro-acetone (Weltner, *B.* 17, 67). Liquid. Warm conc. HCl changes it to pyrotritaric ether $C_7H_7O_3Et$. Water at 160° produces some acetonyl-acetone.

ACETONYL-ACETONE $C_6H_{10}O_2$ *i.e.* $CH_3.CO.CH_2.CH_2.CO.CH_3$. *Di-methylethylene di-ketone.* (188° uncor.)

Formation.—(1) By heating pyrotritaric acid (di-methyl-furfurane-carboxylic acid) with water at 150°–160°; yield nearly theoretical. (2) By heating acetonyl-aceto-acetic ether with water at about 160°; small yield.

Properties.—Mobile liquid of peculiar smell. Miscible with water, alcohol, and ether, insol. conc. KOHAq, or K_2CO_3Aq.

Reactions.—P_2S_5, when heated with it, forms thioxene C_6H_8S.—Heating with alcoholic NH_3 gives di-methyl-pyrrol (Paal, *B.* 18, 2251); *amines* behave similarly (Paal a. Schneider, *B.* 19, 3156).

Di-oxim $CH_3.C(NOH).CH_2.CH_2.C(NOH).CH_3$ [135°]. White glistening plates, v. sol. hot water, alcohol, or ether, v. sl. sol. benzene.

Di-phenyl-di-hydrazide $C_2H_4(CMe{:}N_2HPh)_2$ [120°]: plates, v. sol. alcohol, ether, or benzene, nearly insol. light petroleum (Paal, *B.* 18, 58).

ACETONYL-CARBAMATE $C_5H_7NO_3$ [76°]. Formed by boiling acetonyl thiocarbamate (*infra*) with lead acetate or silver oxide. Crystallises from water in prisms, may be distilled; dissolves in water, alcohol, and ether, Decomposed by heating with strong hydrochloric acid or baryta-water, yielding CO_2, NH_3, and α-oxy-iso-butyric acid. The salts $C_5H_6AgNO_3$, and $AgNO_3.2C_5H_7NO_3$ are crystalline (Urech, *B.* 11, 467; 13, 485). H. W.

ACETONYL-PHOSPHINIC ACID $C_3H_7PO_3$ *i.e.* $CH_3.CO.CH_2.P(OH)_2$. Residue left after distilling acetone with I and P (*v. Acetone-phosphorous acid* under ACETONE). *Salt.*—$Ba(C_3H_6PO_3)_2$.

Di-acetonyl phosphinic Acid *v.* DI-ACETONE-PHOSPHINIC ACID.

Di-acetonyl-phosphorous Chloride *v.* DI-ACETONE-PHOSPHOROUS CHLORIDE.

ACETONYL-QUINOLINE $C_{12}H_{11}NO$ *i.e.*

$$C_6H_4\begin{cases}CH{:}CH \\ \quad\quad\;| \\ N\;\;{:}C{-}CH_2.CO.CH_3\end{cases}$$

Quinolyl-acetone. [76°]. Prepared by reducing *o*-nitro-cinnamoyl-acetone in alcoholic solution with $SnCl_2$. Long yellow needles. Distils without decomposition. Sparingly volatile with steam. Insol. cold water, sl. sol. hot water. Dyes wool and silk yellow. Heated with strong HCl at 170° it gives (*Py.* 3)-methyl-quinoline (Fischer a. Kuzel, *B.* 16, 163).

ACETONYL-THIO-CARBAMATE (so called) $C_5H_7NSO_2$. *Thiacetonuramic acid.* [15[illegible]°].

Formed by treating acetone with a mixture of potassium cyanide and sulphocyanide, and HCl: $C_3H_6O + CNH + CNSH + H_2O = NH_3 + C_5H_7NSO_2$. Long needles; easily sublimable; very soluble in ether; less easily in cold water. Resolved by heating with HCl in a sealed tube at 120° into CO_2, H_2S, NH_3, and α-oxy-iso-butyric acid. The silver salt $C_5H_6AgNSO_2$ is very sparingly soluble (Urech, *B.* 6, 1117). H. W.

ACETONYL-UREA *v.* DI-METHYL HYDANTOÏN.

ACETO-PHENINE *v.* ACETOPHENONE, *Reaction* 6.

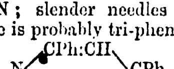
ACETO-PHENONE C_8H_8O *i.e.* $C_6H_5.CO.CH_3$. *Phenyl methyl ketone*, *Acetyl-benzene*. M. w. 120. [20·5°]. (202° cor.). S. G. $\frac{15}{}$ 1·032.

Formation.—1. By distilling calcium benzoate with calcium acetate (Friedel, *A.* 108 122).—2. From BzCl and $ZnMe_2$ (Popoff, *A.* 161, 296).—3. By action of KOHAq on benzoyl-aceto-acetic ether. — 4. From phenyl-acetylene by shaking with diluted (75 p.c.) H_2SO_4 (Friedel a. Balsohn, *Bl.* [2] 35, 54): $Ph.C⋮CH + H_2O = Ph.CO.CH_3$.—5. From bromo-styrene and H_2SO_4: small yield.—6. Bromo-styrene heated with a large excess of water for 12 hours at 180° yields 66 per cent. (Friedel a. Balsohn, *Bl.* [2] 32, 613).—7. From ethyl-benzene and chromic acid in acetic acid (F. a. B.).—8. From di-bromo-phenyl-propionic acid, $CH_2Br.CBrPh.CO_2H$ by boiling water (Fittig a. Wurster, *A.* 195, 160).

Preparation.—From benzene (10 pts.), acetyl chloride (1 pt.), and $AlCl_3$ (2 pts.) (Richter).

Properties.—Large plates. Does not combine with $NaHSO_3$ but, like other ketones, it reacts with hydroxylamine, phenyl-hydrazine, and HCN.

Reactions.—1. *Chromic-mixture* oxidises it to benzoic and carbonic acids (Popoff).—2. *Sodium-amalgam* reduces it to phenyl methyl carbinol, $CH_3.CHPh.OH$, and acetophenone-pinacone.—3. With HI and P at 140° it gives di-phenyl-di-methyl-ethane, $C_{16}H_{18}$, and a compound $C_{16}H_{16}O$ (Graebe, *B.* 7, 1626; *v.* ACETOPHENONE-PINACOLINE).—4. *Chlorine* produces chloro-acetophenone $Ph.CO.CH_2.Cl$ [59°] (245°) and di-chloro-acetophenone $Ph.CO.CHCl_2$ (250°-255°) *v.* CHLORO-ACETOPHENONE.—5. *Bromine* in CS_2 produces bromo-acetophenone, $Ph.CO.CH_2Br$ [50°] *v.* BROMO-ACETOPHENONE.—6. *Ammonia* in presence of P_2O_5 forms 'acetophenine' $C_{24}H_{17}N$ together with methane. Acetophenine crystallises from alcohol in slender needles, which may be sublimed. It is a weak base; its hydrochloride crystallises in plates, decomposed by water into HCl and the base. Fuming HNO_3 forms tri-nitro-acetophenine $C_{23}H_{14}(NO_2)_3N$; slender needles (from ether). Acetophenine is probably tri-phenyl-pyridine:



$$N\begin{cases}\diagup CPh{:}CH\diagdown \\ \diagdown\!\!\diagdown CPh.CH\diagup\!\!\diagup\end{cases}CPh$$

(Engler a. Riehm, *B.* 19, 40).—7. When taken internally it reappears in the urine as hippuric acid, having, doubtless, been previously oxidised as in *Reaction* 1 (M. Nencki, *J. pr.* 123, 288).

Besides the derivatives described below, see also: AMIDO-ACETOPHENONE, BROMO-ACETOPHENONE, BROMO-NITRO-ACETOPHENONE, IODO-ACETOPHENONE, DI-METHYL-AMIDO-ACETOPHENONE, NITRO-ACETOPHENONE, THIO-ACETOPHENONE, ACETOPHEN-OXIM.

ACETOPHENONE-ACETO-ACETIC ACID $C_{12}H_{12}O_4$ *i.e.* $CH_3.CO.CH(CO_2H).CH_2CO.C_6H_5$ *Acetophenone-acetone-carboxylic acid* [130°-140°]. Small colourless crystals. Obtained by saponification of the ether which is prepared by the action of ω-bromo-acetophenone on sodio-aceto-acetic ether. It is very unstable. On warming with absolute alcohol it evolves CO_2 and yields acetophenone-acetone $CH_3.CO.CH_2.CH_2.CO.C_6H_5$ (Paal, *B.* 16, 2865). Acetophenone-aceto-acetic ether is reduced by sodium amalgam to a oily lactone, $\underbrace{CH_3.CH.CH_2.CH(CHMeOH).CO.O}$, sol. aqueous KOH or $Ba(OH)_2$ but insol. aqueous K_2CO_3 (Weltner, *B.* 17, 69). *Amines* convert acetophenone aceto-acetic ether into derivatives of pyrrol (Paal a. Schneider, *B.* 19, 3156).

Dehydro-acetophenone-aceto-acetic acid $C_{12}H_{10}O_3$ [114°]. From acetophenone-aceto-acetic ether $C_6H_5.CO.CH_2.CH(CO_2Et).CO.CH_3$ by heating with alcoholic KOH. Large crystals (from benzene mixed with benzoline). From dilute alcohol it separates in hydrated needles [115°-120°]. By boiling with HCl it is converted into phenyl-methyl-furfurane-carboxylic acid

$$\begin{matrix}HC & - & C(CO_2H)\\ /\!/ & & \diagdown\!\!\diagdown\\ PhC & -O- & CMe.\end{matrix}$$

Salts.—KA'. Long silky needles (from alcohol). NH_4A'.

Oxim $C_{12}H_{12}N_2O_3$: [172°]; glistening white plates; sparingly soluble in water, easily in alcohol, ether, benzene, aqueous acids, and alkalis.

Phenyl-hydrazide $C_{18}H_{16}N_2O_2$: small needles (Paal, *B.* 17, 916, 2761).

ACETOPHENONE-ACETONE $C_{11}H_{12}O_2$ *i.e.* $CH_3.CO.CH_2.CH_2.CO.C_6H_5$ (*acetyl-benzoyl-ethane* or *ethylene methyl phenyl di-ketone*). Prepared by heating acetophenone-aceto-acetic acid (*q.v.*) with absolute alcohol. Yellowish heavy oil. Sl. sol. water, quite insol. alkalis. Cannot be distilled (Paal, *B.* 16, 2868).

Reactions.—1. P_2O_5 removes H_2O forming phenyl-methyl-furfurane,

$$\begin{matrix}CH & - & CH\\ \| & & \|\\ MeC & .O. & CPh.\end{matrix}$$

2. Heated with P_2S_5 it gives, similarly, phenyl-methyl-thiophene,

$$\begin{matrix}CH & - & CH\\ \| & & \|\\ MeC & .S. & CPh.\end{matrix}$$

3. Heated with alcoholic NH_3 it gives, similarly, phenyl-methyl-pyrrol,

$$\begin{matrix}CH & - & CH\\ \| & & \|\\ MeC & .NH. & CPh\end{matrix}$$

(Paal, *B.* 18, 367).

Oxim $C_{11}H_{13}NO_2$. [123°]. Formed by action of hydroxylamine. Long white needles, soluble in acids or alkalis.

Phenyl-hydrazide $C_{17}H_{18}N_2O$ [c. 105°]. White prisms, got by adding phenyl-hydrazine slowly to a solution of the ketone in ether (3 vols.). V. sol. ether or benzene, nearly insoluble in light petroleum (Paal, *B.* 17, 2763).

$C_{17}H_{16}N_2$ [155°]. Formed by mixing the ketone with phenyl-hydrazine (cf. Knorr, *B.* 18, 305).

Dehydro-acetophenone-acetone $C_{11}H_{10}O$. [83°]. This body is formed together with the isomeric phenyl-methyl-FURFURANE by the action of Ac_2O and other dehydrating agents upon acetophenone-acetone. Cannot be distilled, even with steam. It combines with bromine, and gives with phenyl-hydrazine the same compound,

$C_{17}H_{16}N_2$ [155°], that the acetophenone-acetone itself gives. Hence its constitution must be something like $CH_3.CO.CH_2.C{:}C.C_6H_5$.

ACETOPHENONE ALCOHOL $C_8H_8O_2$ *i.e.* $C_6H_5.CO.CH_2OH$ *v.* Benzoyl-carbinol. An isomeric body, $C_6H_4(OH).CO.CH_3$, is described as oxy-acetophenone.

ACETOPHENONE-ANILIDE *v.* Phenyl-amido-acetophenone.

ACETOPHENONE-BENZIL $C_{22}H_{18}O_3$ [102°]. Acetophenone and powdered benzil in equivalent proportions are shaken with an excess of conc. KOH (S. G. 1·27). After a few days a solid cake is formed, which is washed with water and then treated with ether. This leaves dehydro-acetophenone-benzil undissolved, and on evaporation deposits oblique prisms of acetophenone-benzil, which should be recrystallised from alcohol. It is v. sol. ether or hot alcohol, sl. sol. cold alcohol. Above its melting-point it gives off acetophenone. Its constitution is probably Ph.CO.CPh(OH).CH_2.CO.Ph (Japp a. Miller, *C. J.* 47, 34).

Dehydro-acetophenone benzil $C_{22}H_{16}O_2$ [129°].

Formation.—See above.

Preparation.—Equivalent quantities of acetophenone are shaken with excess of conc. KOH (S.G. 1·27) and kept liquid for some hours by the application of sufficient heat. The product is treated as described above, but ether extracts hardly anything. The residue insoluble in ether is crystallised from alcohol (J. a. M.).

$$C_{14}H_{10}O_2 + C_8H_8O = C_{22}H_{16}O_2 + H_2O.$$

Properties.—Tufts of flat needles (from alcohol). V. sl. sol. ether or cold alcohol, v. sol. boiling alcohol.

Reactions.—*Bromine* added to its solution in chloroform unites forming large reddish crystals which are apparently the tetrabromide $C_{22}H_{16}O_2Br_4$ [110°–115°]. Becomes dark at 70°, and pale again at 80°. The bromine is given off in a few weeks over lime.

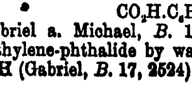
Constitution.—Dehydro-acetophenone-benzil differs from dehydro-acetone-benzil not only in forming a bromide but also in having a very much lower melting-point than would be expected if they were of analogous structure. Japp a. Miller assign to dehydro-acetone-benzil the formula $Ph.CO.CPh{<}{}^{CH_2}_{CH_2}{>}CO$, and the unsaturated formula Ph.CO.CPh:CH.CO.Ph to dehydro-acetophenone-benzil. The latter formula can, however, account only for a di- and not for a tetra-bromide (*C. J.* 47, 37).

ACETOPHENONE CARBOXYLIC ACIDS.

Acetophenone ω-Carboxylic Acid $C_9H_8O_3$ $C_6H_5.CO.CH_2.CO_2H$ *v.* Benzoyl-acetic acid.

Acetophenone *o*-Carboxylic Acid [1 : 2] $CO_2H.C_6H_4.CO.CH_3$. *o-Acetyl-benzoic acid.* [115°].

Formation.—1. Together with CO_2, from acetophenone di-carboxylic acid by heating, long boiling with water, or by potash-fusion.—2. By heating phthalyl-acetic acid with water at 200°:



$+ H_2O =$

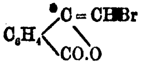
$CO_2H.C_6H_4.CO.CH_3 + CO_2$

(Gabriel a. Michael, *B.* 10, 1554).—3. From methylene-phthalide by warming with aqueous KOH (Gabriel, *B.* 17, 2524):

$+ H_2O = CO_2H.C_6H_4.CO.CH_3.$

Properties.—Broad crystals, with sweet taste.

Reactions.—1. Bromine and glacial acetic acid at 100° convert it into bromo-methylene-phthalide



2. Conc. H_2SO_4 forms, in the cold, two bodies, $C_{18}H_{12}O_4$ [216°] and $C_{18}H_{14}O_5$ [c. 134°]. The latter body is a monobasic acid, di-acetophenone carboxylic acid, and splits up into CO_2 and the former body when it is heated above its melting-point (W. Roser, *B.* 17, 2620; Gabriel, *B.* 17, 2665).—3. Alcoholic NH_3 for fourteen hours at 100° forms a base, $C_{18}H_{17}N_3O_2$ [204°–210°] It crystallises in long needles, insol. water or alcohol and gives a nitroso-derivative [246°] (Gabriel, *B.* 18, 1258).—4. Ac_2O and NaOAc form $Ac.C_6H_4.CO_2Ac$ [71°]; needles, insol. alkalis (Gabriel, *B.* 14, 921).

Phenyl-hydrazide

$$CO_2H.C_6H_4.CMe(N_2HPh)$$

[102°]. Small prisms or large tables, v. e. sol. alcohol (Roser, *B.* 18, 804).

Oxim.—The anhydride of this body,

[159°] is formed by the action of hydroxylamine (base) on acetophenone-*o*-carboxylic ether, or of hydroxylamine hydrochloride upon acetophenone di-carboxylic ether. It is also got, together with CO_2, when the oxim of acetophenone di-carboxylic acid is heated. It crystallises in colourless needles (Gabriel, *B.* 16, 1993).

Acetophenone *p*-Carboxylic Acid $C_9H_8O_3$ [1 : 4] $CO_2H.C_6H_4.CO.CH_3$. [200°]. Formed, together with terephthalic acid, by warming *exo*-oxy-isopropyl-benzoic acid $Me_2C(OH).C_6H_4.CO_2H$ with chromic mixture (R. Meyer, *B.* 12, 1071; *A.* 219, 259). The process is similar to that by which tri-methyl-carbinol is converted into acetone. Needles (from water). May be sublimed. V. sl. sol. cold water, sl. sol. hot water, alcohol or ether.

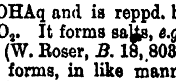
Salts.—$BaA'_2\frac{1}{2}aq$.—CuA'_2aq.—$PbA'_2 1\frac{1}{2}aq$.—AgA′.

Methyl ether.—MeA′, [92°]. Small needles.

Acetophenone *o*-ω-di-carboxylic acid $C_{10}H_8O_5aq$ *i.e.* $CO_2H.C_6H_4.CO.CH_2.CO_2H$ aq. *Benzoyl-acet-carboxylic acid.* [90°]. Formed by dissolving phthalyl-acetic acid (*q. v.*) in cold aqueous NaOH and ppg. by HCl (Gabriel a. Michael, *B.* 10, 1553). It behaves, therefore, as if phthalyl-acetic acid were its anhydride. Broad needles (from water). On melting, it splits up into H_2O, CO_2 and acetophenone *o*-carboxylic acid (*q. v.*).

Salt: AgA′: granular pp.

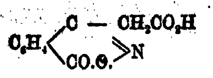
Phenyl-hydrazine, in alcoholic solution in presence of HOAc, forms the anhydride of the phenyl-hydrazide:



$$C_6H_4{<}{}^{C-CH_2.CO_2H}_{CO}{>}N_2Ph$$

It is soluble in NaOHAq and is reppd. by HCl. [160°] giving off CO_2. It forms salts, *e.g.*: $(C_{16}H_{11}N_2O_3)_2Ca3aq$ (W. Roser, *B.* 18, 808).

Hydroxylamine forms, in like manner, not the *oxim* but its anhydride:



$$C_6H_4\left\langle\begin{matrix}C - CH_2CO_2H \\ CO.O.\end{matrix}\right\rangle N$$

[c. 150°]. This is a mono-basic acid, and splits up, when heated, into CO_2 and the anhydride of the oxim of acetophenone-*o*-carboxylic acid (*above*).

ACETOPHENONE CHLORIDE *v.* DI-CHLORO-ETHYL-BENZENE.

ACETOPHENONE CYANHYDRIN C_9H_9NO, *i.e.* Ph.C(OH)(CN).Me *a-oxy-a-phenyl-propio-nitrile, a-oxy-hydro-atropo-nitrile.* Formed by mixing acetophenone with KCN, and adding fuming HCl (Spiegel, *B.* 14, 235). A brown oil.

Reactions.—1. KOHAq gives atrolactic acid, Ph.CMe(OH).CO_2H.—2. HCl at 130° gives chloro-hydro-atropic acid: Ph.CH(CH_2Cl).CO_2H (Spiegel, *B.* 14, 1352).—3. *Ammonia* forms Ph.C(NH_2)(CN).Me (Tiemann a. Köhler, *B.* 14, 1980).

ACETOPHENONE-DI-METHYL-ANILINE *v.* DI-METHYL-AMIDO-BENZYL PHENYL KETONE.

ACETOPHENONE DI-METHYL-HYDRAZIDE $C_{10}H_{14}N_2$, *i.e.* PhCMe:N_2Me_2(165°) at 190 mm. Formed from acetophenone and di-methyl-hydrazine at 100° (Riesenegger, *B.* 16, 663).

ACETOPHENONE NITRANILIDE *v.* NITRO-PHENYL-AMIDO-ACETOPHENONE.

ACETOPHENONE PHENYL-HYDRAZIDE $C_{14}H_{14}N_2$ *i.e.* CPhMe:N_2PhH [105°]. Formed by shaking acetophenone suspended in water with a solution of phenyl-hydrazine hydrochloride and sodium acetate (Fischer, *B.* 17, 576). Also by allowing a conc. alcoholic solution of phenyl-hydrazine and acetophenone to stand for a day (Riesenegger, *B.* 16, 661), or by heating the oxim with phenyl-hydrazine (Just, *B.* 19, 1206). Slender white needles or plates. V. sol. ether, sl. sol. water or cold alcohol.

ACETOPHENONE-(β)-PINACOLINE $C_{16}H_{16}O$, *i.e.* Ph_2CMe.CO.CH_3 (?). [41°]. (310° uncorr.). Prepared by the action of zinc and HCl on an alcoholic solution of acetophenone. Rhombic prisms or short pillars. Soluble in C_6H_6, ether, acetic acid, hot alcohol, &c. By heating with soda-lime it gives HOAc and di-phenyl-methyl-methane, $Ph_2CH.CH_3$. On reduction with HI and P, it gives a hydrocarbon $C_{16}H_{18}$ [128°], which is apparently identical with the hydrocarbon formed by the action of Na on bromo-ethyl-benzene: PhCHMe.CHMePh. CrO_3 oxidises it to di-phenyl-propionic acid, $CH_3CPh_2CO_2H$.

It An isomeric acetophenone-pinacoline [70°] in pl43° i. V.) is formed when acetophenone is base. Fuwith HI and P at 140° (Graebe, *B.* 7, $C_{23}H_{14}(NO_2$, forms plates or tables (from alcohol). Acetopheninacked by AcCl; HI reduces it to the $C_{16}H_{18}$ (Thörner a. Zincke, *B.* 11.

PHENONE, THIO-ACETOPHENONE, ACETOPHEN-

ACETOPHEN-OXIM C_8H_9NO, *i.e.* PhCMe:NOH [59°]. *Phenyl methyl ketoxim.* Formed by mixing alcoholic solutions of acetophenone and hydroxylamine; after 24 hours, the alcohol is distilled off, and the product crystallised from water. It forms colourless silky needles. Volatile with steam; soluble in hot water, alcohol, ether, benzene, chloroform, or benzoline. Soluble in acids and in alkalis.

ACETO-PROPIONIC ACID *v.* ACETYL-PROPIONIC ACID.

ACETO-SINAPIC ACID *v.* SINAPIC ACID.

ACETO-SUCCINIC ACID *v.* ACETYL-SUCCINIC ACID.

ACETO-THIENONE *v.* THIENYL METHYL KETONE.

ACETO-THIO-TOLUIDIDE *v.* THIO-ACETYL-TOLUIDINE.

ACETO-VALERIC ACID *v.* ACETYL-VALERIC ACID.

ACETOXIM C_3H_7NO, *i.e.* Me_2C:NOH *Di-methyl-ketoxim, acetone hydroxylamide* [60°] (135° i. V.) at 730 mm. Prepared by leaving an aqueous solution of acetone mixed with hydroxylamine hydrochloride, neutralised with NaOH, to stand for 24 hours; and extracting with ether (V. Meyer a. Janny, *B.* 15, 1324).

Properties.—Colourless prisms; extremely volatile and smelling like chloral. Very soluble in water, alcohol, ether, or benzoline. Neutral to litmus. Ether extracts it from a neutral, but not from an acid or alkaline, solution. It is readily decomposed by boiling acids (even acetic) into acetone and hydroxylamine. Acid reducing agents have a like effect, but zinc dust and NaOH does not affect it.

B'HCl, white powder [c. 100°], very unstable, formed by passing HCl gas into a dry ethereal solution of acetoxim.—C_3H_7NONaOEt, crystalline scales, got by adding NaOEt to an ethereal solution.

Benzoyl derivative Me_2C:N(OBz), [42°], small colourless tables, very soluble in alcohol and ether, slightly in water; formed by the action of benzoyl chloride on acetoxim.

Benzyl ether Me_2C:N(OC_7H_7), (c. 190°), oily fluid, soluble in alcohol and ether, insoluble in water; formed by the action of benzyl chloride and sodium ethylate on acetoxim; on warming with aqueous HCl, it is split up into benzyl-hydroxylamine ($H_2N.OC_7H_7$) and acetone (Janny, *B.* 16, 170).

ACETOXIMIC ACID $C_3H_6N_2O_2$, *i.e.* CH_3.C(NOH).CH(NOH). *Nitroso-acetoxim, Di-nitroso-propane* [153°]. *Formation.*—(1) By the action of hydroxylamine on *u*-di-chlor-acetone (CH_3.CO.$CHCl_2$).—(2) By the action of hydroxylamine on nitroso-acetone (CH_3.CO.CH(NOH)) (Meyer a. Janny, *B.* 15, 1165). Small prisms. Soluble in alcohol, ether, and hot water. Its alkaline solutions are colourless.

ACETOXYL. Kolbe's name for ACETYL. Now used to denote $C_2H_3O_2$.

ACET-TOLUIDE *v.* *Acetyl*-TOLUIDINE.

ACET-TOLYL-IMID-TOLYL-AMIDE *v.* TOLYL-ACETAMIDINE.

ACETURIC ACID $C_4H_7NO_3$ *i.e.* CH_2(NHAc).CO_2H (*acetyl-glycocoll, acetyl-glycine*, or *acetamido-acetic acid*). [206°]. S. (at 15°) 2·7.

Formation**: 1. By heating glycocoll with**

Ac_2O. **2.** By heating glycocoll-silver with acetylchloride (Kraut a. Hartmann, *A.* 138, 99).

Long colourless crystals, readily soluble in hot water and in alcohol, insoluble in ether, chloroform and benzene.

Reactions.—Gives a red coloration with Fe_2Cl_6. Readily saponified by boiling with acids or alkalis.

Salts.—A'NH$_4$ aq: soluble needles or large tables.—A'Ag: soluble plates.—A'_2Ba5aq: easily soluble needles.—A'_2Cu4½aq: blue trimetric prisms, easily soluble in water and in alcohol.—A'HHCl$^{\times}$: needles, decomposed by water.

Methyl ether.—A'Me, [59°], (254°) at 712 mm., long colourless tables, easily soluble in water, alcohol, and benzene, sparingly in ether.

Ethyl ether.—A'Et, [48°], (260°) at 712 mm., trimetric plates.

Amide $CH_2(NHAc).CO.NH_2$—[137°], large colourless tables, soluble in water and alcohol, insoluble in ether (Curtius, *B.* 17, 1663).

ACETUREÏDE *v. Acetyl*-Urea.

ACET-XYLIDE *v. Acetyl*-Xylidine.

ACETYL C_2H_3O, $CO.CH_3$, COMe or Ac. The radicle of acetic acid, &c. The name *Acetyl* was formerly applied to the radicle C_2H_3. The prefix *acet-* often indicates the radicle $CH_3.C$: as in acetamidine; sometimes it is merely a contraction for acetyl, as in acet-xylide. The acetyl derivatives obtained by displacing H in OH or in NH_2 or in NH are described under the compounds from which they are derived by this displacement.

DI-ACETYL $C_4H_6O_2$ *i.e.* $CH_3.CO.CO.CH_3$. The oxim, $CH_3.C(NOH).C(NOH).CH_3$, of this hypothetical body, called also *di-methyl-glyoxim* or *methyl-ethyl-acetoximic acid*, is formed by adding hydroxylamine hydrochloride to an aqueous solution of methyl oximido-ethyl ketone, $CH_3.CO.C(NOH).CH_3$. Glittering needles (Schramm, *B.* 16, 180).

DI-ACETYL-ACETONE DI-CARBOXYLIC ACID *v.* Aceto-acetic ether, *Reaction* 32.

ACETYL-ACETOPHENONE *v.* Benzoyl-acetone.

ACETYL-ACRYLIC ACID *v.* Tetric acid.

DI-a_1-a_2-ACETYL-ADIPIC ACID $C_{10}H_{14}O_6$ *i.e.* $CO_2H.CHAc.CH_2.CH_2.CHAc.CO_2H$.

Di-ethyl-ether.—Et_2A''. Formed as a by-product (20 p.c.) of the action of ethylene bromide upon sodio-aceto-acetic ether, and found in the residue after distilling with steam. It is a thick colourless oil; its alcoholic solution gives a dark reddish-violet coloration with Fe_2Cl_6.

Reactions.—1. It gives a tolerably stable di-sodio-derivative which, on treatment with *iodine*, yields the di-ethylic ether of di-acetyl-tetra-methylene-di-carboxylic-acid, $\begin{array}{l}CH_2CAc.CO_2H\\ |\quad\ \ |\\ CH_2CAc.CO_2H\end{array}$; an acid which crystallises (with 2aq) in pearly scales [210°].—2. By conc. NH_3 di-acetyl-adipic ether is converted into the ketone-imide, $C_{14}H_{24}N_2O_4$ [177°].—3. *Phenyl-hydrazine* forms the phenyl-hydrazide [145°], which readily splits off alcohol giving ethylene-di-methyl-di-oxy-di-quinizine,

$$C_6H_4\left<\begin{array}{l}N_2H{:}CMe\\ CO\end{array}\right.\begin{array}{l}\qquad\qquad\qquad\qquad\quad Me.C{:}HN_2\\ .\ CH.CH_2.CH_2.CH.CO\end{array}\right>C_6H_4$$

4. By *distillation*, or on solution in conc. H_2SO_4, it loses H_2O, giving an ether $C_{14}H_{20}O_5$ which probably has the constitution

$$CH\left<\begin{array}{l}CMe.CH(CO_2Et).CH_2\\ CO\ .\ CH(CO_2Et).CH_2\end{array}\right>$$

The corresponding acid, [189°], forms a phenyl-hydrazide, $C_{10}H_{12}O_4(N_2PhH)$ [192°] (Perkin a. Obrembsky, *B.* 19, 2051).

ACETYL-AMIDO COMPOUNDS *v.* Amido compounds.

ACETYL-BENZOIC ACID *v.* Acetophenone carboxylic acid.

ACETYL-BENZOYL-ETHANE *v.* Acetophenone-acetone.

ACETYL-BENZOYL-ETHANE CARBOXYLIC ACID *v.* Acetophenone-aceto-acetic acid.

ACETYL-BENZYL-SUCCINIC ETHER $C_{17}H_{22}O_5$ *i.e.* $CO_2Et.CAc(CH_2Ph).CH_2.CO_2Et$ (310°) S. G. $\frac{15}{15}$ 1·088. Prepared by the action of benzyl chloride on a mixture of sodium ethylate and acetyl-succinic ether (Conrad, *B.* 11, 1058).

ACETYL BROMIDE C_2H_3OBr *i.e.* $CH_3.CO.Br$. *Acetic bromide* (81°). Formed by treating acetic acid with PBr_3 (Ritter, *A.* 95, 209). Prepared by gradually adding 240 g. bromine to a mixture of 90 g. glacial acetic acid and 33 g. amorphous phosphorus, and distilling when the action is complete (Gal, *A.* 129, 537). Hanriot (*A. Ch.* [5] 17, 83) uses 1 pt. phosphorus, 15 acetic acid and 40 bromine. Colourless fuming liquid. Heated with bromine at 100° in a sealed tube, it yields bromacetyl-bromide $C_2H_2BrO.Br$, together with more highly brominated compounds, which may be separated by fractional distillation (Gal). On the action of bromine on C_2H_3OBr, see also Urech (*B.* 13, 1720; *J.* 1880, 386). H. W.

ACETYL-BUTANE-PHOSPHONIC ACID *v.* di-Acetone-phosphinic acid.

ACETYL-BUTYL ALCOHOL $C_6H_{12}O_2$.

Di-acetonic alcohol $CH_3.CO.CH_2.CMe_2.OH$. (164°). S.G. $\frac{25}{}$ ·931.

Preparation.—Acid oxalate of di-acetonamine (1 pt.) is dissolved in water (3 pts.) and cooled to 5°, when it deposits some of the salt; solid KNO_2 (2 pts.) is slowly added, and the mixture kept cool for some days and then heated to 50° or 60°; the oily layer (mesityl oxide) is removed partly by distillation, partly by a tap-funnel; and the aqueous solution, neutralised with K_2CO_3, is shaken with ether (Heintz, *A.* 169, 114; 178, 342).

Properties.—Syrup, miscible with water, alcohol, or ether, gives off hydrogen when treated with Na.

γ-Acetyl-*n*-butyl Alcohol $C_6H_{12}O_2$ *i.e.* $CH_3.CO.CH_2.CH_2.CH_2.CH_2OH$. *Methyl δ-oxy-n-butyl ketone.* (155°) at 718 mm. S.G. $\frac{0}{}$ 1·0148.

Formation.—1. From bromo-propyl-aceto-acetic ether (50 g.) by boiling for an hour with water (50 g.) and HCl (20 g. of S.G. 1·18) (Lipp, *B.* 18, 3280).—2. From so-called tetra-methylene methyl ketone carboxylic acid by boiling with water (Perkin, jun., *B.* 19, 2557).

Properties.—Liquid with camphor-like smell, v. sol. water, alcohol, and ether; scarcely volatile with steam. It does not reduce Fehling's solution or ammoniacal $AgNO_3$. *Chromic mixture* oxidises it to δ-acetyl-*n*-butyric acid. *Sodium amalgam* reduces it to ω-δ-di-oxy-hexane.

Anhydride $C_6H_{10}O$ *i.e.* $CH_2\left<\begin{array}{l}CH{:}CMe\\ CH_2.CH_2\end{array}\right>O$. Oil. Formed by distilling the alcohol or the following acid.

Tetra-methylene methyl ketone carboxylic acid, $C_7H_{10}O_3$, appears to be a carboxylic acid formed from the anhydride of acetyl-butyl alcohol:

$$CH_2\left\langle\begin{matrix}C(CO_2H):CMe\\ CH_2\ \ .\ \ CH_2\end{matrix}\right\rangle O.$$

Its ethyl ether $C_9H_{14}O_3$, (223°), M.M. 10·195, is formed by the action of trimethylene bromide on aceto-acetic ether (*v.* p. 24).

ACETYL-BUTYL BROMIDE $C_6H_{11}BrO$ *i.e.* $CH_3.CO.CH_2.CH_2.CH_2.CH_2.Br$. (215°) at 718 mm. From the preceding acid, $C_7H_{10}O_3$, or from acetyl-butyl alcohol by the action of HBr. Also formed by heating bromo-propyl-aceto-acetic ether with dilute acids. It is a colourless oil, v. sol. alcohol or ether, v. sl. sol. water; boiling water converts it into the alcohol (Lipp, *B.* 18, 3281; Perkin, *B.* 19, 2557).

ACETYL-BUTYRIC ACIDS $C_6H_{10}O_3$.

α-Acetyl-*n*-butyric acid $CH_3.CH_2.CHAc.CO_2H$ *v. Ethyl-aceto-acetic acid* under ACETO-ACETIC ACID.

β-Acetyl-*n*-butyric acid $CH_3.CHAc.CH_2.CO_2H$. [c.–12°]. (242°). Formed, together with its ether, by boiling α-acetyl-α-methyl-succinic ether, $CO_2Et.CMeAc.CH_2.CO_2Et$, with HCl (Bischoff, *A.* 206, 331).

Very hygroscopic liquid. V. sol. water, alcohol, or ether. Oxidises in air. Hot dilute HNO_3 forms pyrotartaric acid.

Salts. — ZnA'_2 (at 100°): nodules (from alcohol). The salts of the alkalis and alkaline earths are syrupy, the lead salt may be got as a vitreous mass.

Ether.—EtA' (204° 205°). Oil.

γ-Acetyl-*n*-butyric acid $CH_2Ac.CH_2.CH_2.CO_2H$ [13°]. (c. 275° i. V.). From sodium aceto-acetic ether and β-iodopropionic ether (Fittig a. Wolff, *A.* 216, 127). Thick liquid. V. sol. water, alcohol, or ether. Solutions are acid and decompose Na_2CO_3. Forms a crystalline compound with water, $CH_3.C(OH)_2.CH_2.CH_2.CH_2.CO_2H$ [35°–36°] which forms monoclinic prisms,

$$a:b:c = \cdot769:1:\cdot885 \quad \beta = 75°\ 20'.$$

Over H_2SO_4 it loses H_2O, becoming liquid.

Salts. – $Ca(C_6H_9O_3)_2aq.$ — $Pb(C_6H_9O_3)_2aq.$ — ZnA'_2.—AgA'.

Reactions.—Sodium amalgam reduces it to δ-OXY-HEXOIC ACID (*q. v.*).

α-Acetyl-iso-butyric acid $(CH_3)_2CAc.CO_2H$ *v. di-methyl-aceto-acetic acid* under ACETO-ACETIC ACID.

β-Acetyl-iso-butyric acid $CH_2Ac.CMeH.CO_2H$ (248°). Formed, together with its ether and CO_2, by boiling α-acetyl-β-methyl-succinic ether, $CO_2Et.CHAc.CHMe.CO_2Et$, with HCl (Bischoff, *A.* 206, 319). It is a liquid. V. sol. water, alcohol, or ether. Turns brown in air. Dilute HNO_3 forms pyrotartaric acid. The salts are amorphous. The silver salt deposits silver on warming its solution.

Ether.—EtA' (206°–208°). Oil.

ACETYL-TRI-CARBALLYLIC ETHER $C_{14}H_{22}O_7$, *i.e.* $CO_2Et.CH_2.CAc(CO_2Et).CH_2.CO_2Et$. From chloro-acetic ether and sodium acetyl-succinic ether, $CO_2Et.CH_2.CAcNa.CO_2Et$ (Miehle, *A.* 190, 323). It boils with much decomposition at 280°–300°. Boiling baryta water or conc. alcoholic KOH split it up completely into alcohol, acetic, and tri-carballylic, acids.

ACETYL-CARBINOL $C_3H_6O_2$ *i.e.* $CH_3.CO.CH_2OH$. *Pyruvyl alcohol, Oxy-acetone, Acetol.*

Formation.—Conc. H_2SO_4 dissolves β-chloro allyl alcohol, $CH_2:CCl.CH_2OH$, giving off HCl the solution is diluted and distilled (Henry *Bl.* 39, 526).

Ethyl ether.—$CH_3.CO.CH_2.OEt$. (128°) S.G. ^{18} ·92. Formed by heating propargyl ether $CH:C.CH_2OEt$, with water and $HgBr_2$ (Henry *C. R.* 93, 421). Colourless liquid with peculiar odour and burning taste.

Acetyl derivative $C_3H_5O(OAc)$. Colourless fluid. (172°) S.G. ^{11} 1·053. Soluble in water. Prepared by heating potassium acetate with chloracetone. Also from propargyl acetate, water, and $HgBr_2$. The alcohol has not been got by its saponification. Readily reduces ammoniacal silver nitrate or Fehling's solution, the chief product of the oxidation being lactic acid.

Benzoyl derivative $C_3H_5O(OBz)$. Long needles. [24°]. Soluble in hot water, easily in alcohol and ether. Prepared by heating potassium benzoate with chloracetone. (Breuer a. Zincke, *B.* 13, 637.)

ACETYL CHLORIDE $C_2H_3O.Cl$, *i.e.* Ac.Cl. *Acetic chloride.* M.w. 78·5. (50·9° cor.) (Thorpe, *C. J.* 37, 188); (51°–52°) at 720 mm. (Brühl, *A.* 203, 14). S. G. $\frac{0}{4}$ 1·1377 (T.); $\frac{20}{4}$ 1·1051. C. E. (0°–10°) ·001391; (0°–50°) ·001504 S. V. 74·05 (T.). μ_β 1·3954. R_∞ 26·82 (B.). H.F.p. 63,300 (Berthelot).

Formation.—1. From $POCl_3$ and potassic acetate: $3KOAc + POCl_3 = K_3PO_4 + 3AcCl$ (Gerhardt, *A. Ch.* [3] 37, 294).—2. Contained in the more volatile portions of the product of the action of chlorine on aldehyde (Wurtz, *A. Ch.* [3] 49, 58). 3. By distilling glacial acetic acid with PCl_5: $HOAc + PCl_5 = AcCl + ClH + POCl_3$ (Ritter, *A.* 95, 209).

Preparation.—By distilling glacial acetic acid (61g.) with phosphorus trichloride (93g.) (Béchamp, *J.* 1856, 427). The reaction is as follows (Thorpe, *C. J.* 37, 186):

$$3HOAc + 2PCl_3 = 3AcCl + 3HCl + P_2O_3.$$

If more HOAc be used Ac_2O is also formed. The action of PCl_3 is therefore precisely like that of PCl_5, amounting to a displacement of O by Cl_2; the molecule HCl_2Ac, which might be expected to be formed, cannot hold together on account of the monovalent character of chlorine, and so splits up at once into HCl and ClAc. Under precisely similar conditions, alcohol, HOEt, gives HCl and ClEt.

Properties.—Colourless, fuming, mobile, and strongly refracting liquid. Its vapour strongly attacks the eyes and respiratory organs.

Reactions.—1. Violently acted on by *water*, with formation of HCl and acetic acid.—2. With *ammonia* it yields acetamide $AcCl + NH_3 = HCl + AcNH_2$ and with *aniline* in like manner, acetanilide, AcNHPh.—3. Distilled with *potassium acetate* or *benzoate*, it forms acetic or aceto-benzoic oxide: $KOAc + AcCl = KCl + Ac_2O$; and $KOBz + AcCl = KCl + AcOBz$. Similarly with salts of other acids.—4. With *potassium hydrosulphide* it yields acetic hydrosulphide or thioacetic acid, and with *potassium monosulphide* it forms acetic sulphide or thioacetic anhydride, $AcCl + KSH = KCl + AcSH$; and $2AcCl + K_2S = 2KCl + Ac_2S$ (Jacquemin a. Vosselmann, *C. R.* 49, 371).—5. With *potassium nitrite* it gives off nitrosyl-chloride, and towards the end of the reaction NO_2, and on heating the residue to 150°,

acetic anhydride distils over: $AcCl + KNO_2 = NOCl + KOAc$, and $AcCl + KOAc = KCl + Ac_2O$ (Armstrong, *C. J.* 26, 683).—6. *Silver nitrate* acts: $2AcCl + AgNO_3 = AgCl + NO_2 + Cl + Ac_2O$. Similarly with other nitrates: $Hg(NO_3)_2$, $Pb(NO_3)_2$, and KNO_3 are attacked immediately; $Ba(NO_3)_2$ is not affected; $Ca(NO_3)_2$ readily. With KNO_3, chlorine is first evolved, NO_2 only towards the end (Armstrong).—7. With *succinic acid* it yields acetic acid and succinic anhydride,

$$C_2H_4(COOH)_2 + CH_3.CO.Cl = HCl + CH_3.COOH + C_2H_4(CO)_2O;$$

and it reacts in like manner with other dibasic dihydric acids; viz., isodibromosuccinic, phthalic, diphonic, and camphoric acids; isosuccinic, ordinary dibromosuccinic, fumaric, and terephthalic acids are not attacked; sublimed anhydrous oxalic acid is resolved into H_2O, CO, and CO_2; benzoic acid yields benzoic chloride and acetic acid (Anschütz, *B.* 10, 325, 1881).—8. With *titanic chloride*, acetyl chloride forms the compound $TiCl_4AcCl$ (Bertrand, *Bl.* [2] 33, 403). Large transparent octahedral crystals [25°-30°] sol. in CS_2.—9. *Aluminium chloride* reacts according to the equation $Al_2Cl_6 + 4(CH_3.CO)Cl = 4HCl + 2(CH_3.CO.CH:CO),Al_2Cl_6$ (Winogradoff, *Bl.* [2] 34, 325). The product is a solid, decomposed by water into CO_2 and acetone.—10. PCl_5 at 190° forms chloro-acetyl chloride $CH_2Cl.CO.Cl$ (Samosadsky, *Z.* 1870, 105), and trichloro-acetyl chloride, $CCl_3.CO.Cl$ (Hübner, *A.* 120, 330).—11. *Zinc* produces a brown mass whence alcohol extracts 'acetylide,' $C_{16}H_{18}O_4$, which may be ppd. by water. Red plates (from chloroform). Sol. ether, alcohol, HClAq, fuming HNO_3, or Ac_2O. Combines with bromine; does not reduce Fehling's solution (Tommasi a. Quesneville, *C. R.* 76, 496).—12. Acts upon *benzene*, in presence of $AlCl_3$, with formation of acetophenone (*q. v.*).—13. Acts similarly upon *thiophene*, or its mono-haloid derivatives, displacing, in presence of $AlCl_3$, H by Ac. But in di-bromo- or di-iodo-thiophene it displaces, in presence of $AlCl_3$, Br or I by Ac, *e.g.*:

$$C_4H_2SBr_2 + ClAc = C_4H_2SBrAc + ClBr$$

(Gattermann a. Römer, *B.* 19, 688). H. W.

Use in Organic Investigations.—Acetyl chloride evolves HCl when it is heated with any substance containing the radicles hydroxyl, amidogen, or imidogen. Hence, if a substance does not evolve HCl when so treated, it may be assumed to be free from these radicles. If the hydroxyl be alcoholic, *i.e.* attached to an atom of carbon that is not attached to any more oxygen, it will be converted into acetoxyl (AcO); and, if the substance contains no nitrogen, the number of acetoxyls it contains after this treatment gives the number of alcoholic hydroxyls the body contains. Before making the experiment, all carboxyls should be etherified, since the group CO_2H is attacked by AcCl (v. *Reaction* 7), while the group CO_2Et is not attacked. The number of acetyl groups that have entered may in many cases be determined by boiling with standard alkali and subsequent titration (Schiff). Acetyl chloride converts NH_2 into NHAc, but hardly ever into NAc_2. It converts NH into NAc. It has no action upon tertiary amines, hence it can be used in the diagnosis of bases. Acetyl chloride does not act upon hydrogen directly united to carbon, except in presence of $AlCl_3$ or some similar agent.

ACETYL CYANIDE C_3H_3ON or AcCN *Pyruvo-nitrile.* M. w. 69. (93°). V.D. 2·4.

Preparation.—When acetyl chloride and silver cyanide are heated together in a sealed tube at 100°, and the product is distilled, a colourless liquid passes over at 80°-90°, and afterwards a compound having a much higher boiling-point. The first yields acetyl cyanide on rectification.

Properties.—Oil, lighter than water, which gradually dissolves it, forming HCN and HOAc, converted by HCl first into $CH_3.CO.CONH_2$, and subsequently into pyruvic acid (Hübner, *A.* 120, 230; 123, 271; see also Fileti, *G.* 5, 391; *J.* 1875, 510).

Di-acetyl-di-cyanide $C_6H_6O_2N_2$ [69°] (210° cor.). V.D. 4·57 (for 4·77). Formed from acetyl cyanide by heating it with KOH, or even by keeping it for some time in a closed vessel.

Preparation.—Powdered KCN (32 pts.) is boiled with acetic anhydride (50 pts.), diluted with benzene (200 pts.): yield is 25 p.c. of the theoretical (Kleeman, *B.* 18, 256). Glistening tables, sl. sol. hot water, v. sol. alcohol, ether, or benzene. Di-acetyl-di-cyanide, like acetyl cyanide, is converted by boiling with water, H_2SO_4, or KOH, into HCN and AcOH. Heated with $AgNO_3$ it yields AgCN.

ACETYLENE C_2H_2 or $CH\vdots CH$ *Ethine, Ethinene.* M.w. 26. *Physical Properties of liquid acetylene*: S.G. $\frac{0}{}$ ·451; $\frac{10}{}$ ·420; $\frac{24}{}$ ·381. C.E. (-7° to 36°) ·00489. *Vapour-pressure*: 16,340 mm. at 0°; 24,900 mm. at 13·5°. *Critical Point* 37° (G. Ansdell, *Pr.* 29, 209). *Properties of gaseous acetylene*: V.D. ·91. S. 1 at 18°; S. (CS_2 or isopentane) 1; S. (CCl_4 or turpentine oil) 2; S. (amyl alcohol) 3½; S. (benzene) 4; S. (glacial acetic acid or abs. alcohol) 6 (Berthelot, *A. Ch.* [4] 9, 425). H.F.p. −47,770. H.F.v. −47,770 (*Th.*); −64,000 (Berthelot).

Occurrence.—In coal-gas (Boettger, *A.* 109, 351).

Formation.—1. Synthetically by passing hydrogen gas over charcoal heated to whiteness in the electric arc (Berthelot, *C. R.* 54, 640); the hydrogen may be passed through holes drilled through the centre of carbon points discharging powerful sparks (Dewar, *Pr.* 29, 188).—2. By exposing marsh-gas or coal-gas to a strong heat, or to the spark of a powerful induction-coil: $2CH_4 = C_2H_2 + 3H_2$ (Berthelot, *C. R.* 54, 515). Part of the C_2H_2 is, however, polymerised during the process, being converted partly into benzene C_6H_6, partly into black tarry hydrocarbons (Berthelot, *Bl.* [2] 11, 142). The vapours of many other organic compounds, as ethylene, alcohol, ether, acetone, amyl alcohol, and benzene, likewise yield acetylene when induction sparks are passed through them (De Wilde, *Bl.* [2] 6, 267).—3. By the incomplete combustion of hydrocarbons and other organic bodies—abundantly, for example, in a Bunsen lamp, when the flame strikes down and burns within the chimney—also in the incomplete oxidation of organic compounds at ordinary temperatures, as in the voltaic circuit, *e.g.* in the electrolysis of a solution of potassium aconitate or succinate (Berthelot, *Bl.* [2] 9, 103).—4. By the incomplete combustion of mixtures of hydrogen and gaseous or vaporous carbon-com-

pounds not containing hydrogen, e.g. CO, CS_2, CN.—5. *By passing a mixture of methane and* carbon monoxide through a red-hot tube: $CH_4 + CO = H_2O + C_2H_2$.—6. Together with H, CH_4, and free carbon, by passing the vapour of methyl chloride (Berthelot), or of ethylene chloride (De Wilde), or of pentane from American petroleum (Vohl, *Bl.* 4, 302), through a red-hot tube.—7. Together with benzene, by passing styrene vapour through a red-hot tube: $C_8H_8 = C_2H_2 + C_6H_6$ (Berthelot, *J.* 1866, 544).—8. By passing chloroform vapour over red-hot copper: $2CHCl_3 + Cu_6 = 3Cu_2Cl_2 + C_2H_2$ (Berthelot), or by treating chloroform with potassium-amalgam (Kletzinsky, *Z.* 1866, 127), or with sodium (Fittig, *ibid.*). — 9. From iodoform by the action of finely divided silver either alone or mixed with finely divided copper: $2CHI_3 + 3Ag_2 = 6AgI + C_2H_2$. Also by the action of finely divided zinc or of the zinc-copper couple on iodoform in presence of water (P. Cazeneuve, *C. R.* 97, 1371; *Bl.* [2] 41, 156).—10. By passing a mixture of CO and HCl over red-hot magnesium silicide (Berthelot). — 11. By the action of alcoholic potash on bromethylene: $C_2H_3Br + KOH = KBr + H_2O + C_2H_2$ (Sawitsch, *C. R.* 52, 157).—12. By the action of water on calcium carbide (produced by strongly heating an alloy of Zn and Ca with charcoal): $CaC_2 + H_2O = CaO + C_2H_2$ (Wöhler, *A.* 124, 220). 13. Formed, together with succinic acid, by the electrolysis of sodium fumarate or maleate: $C_4H_2Na_2O_4 + H_2O = C_2H_2 + 2CO_2 + Na_2O + H_2$ (Kekulé, *J.* 1864, 389).—14. By heating isethionic acid with potash: $C_2H_4O.SO_3K + KOH = C_2H_2 + K_2SO_3 + 2H_2O$.—15. Formed in small quantity by heating cupric acetate (1 pt.) with water (200 pts.) in a closed flask at 100° (Tommasi, *Bl.* [2] 38, 257).

Preparation.—1. Air is burned in a cylinder full of coal-gas, and a portion of the products of combustion are sucked (by an air-pump) first through a metallic condenser to cool them, and then through several bottles containing an ammoniacal solution of cuprous chloride. A red pp., C_2Cu_2aq, is formed; this is collected, washed by decantation, and warmed with aqueous HCl, when it is decomposed with evolution of acetylene gas: $C_2Cu_2H_2O + 2HCl = C_2H_2 + 2CuCl + H_2O$ (Jungfleisch, *C. R.* 90, 264; *J. Ph.* [5] 1, 307).—2. Ethylene bromide is slowly dropped into a strong alcoholic solution of potash at boiling heat, and the evolved gas is passed through a second similar boiling solution to remove bromethylene (Miasnikoff, *A.* 118, 330; Sawitsch, *A.* 119, 184; Sabanejeff, *A.* 178, 111). To remove the last traces of bromethylene, Zeisel (*A.* 191, 372) recommends passing the gas over moderately heated soda-lime. The gas may also be purified, as in the first method, by passing it through an ammoniacal solution of cuprous chloride.

Properties.—Colourless gas, having a disagreeable odour. According to Zeisel, when prepared from the copper compound as described above, it is contaminated with vinyl chloride. Acetylene is liquefied by a pressure of 83 atmospheres at 18°, forming a mobile, highly refractive liquid, lighter than water. Liquid acetylene dissolves paraffins and many fats (Cailletet, *C. R.* 85, 851).

Reactions.—1. Decomposed by the *induction-spark* with separation of carbon, and partly converted into a liquid and a solid polyacetylene, the latter insoluble in the ordinary solvents.—2. Slowly passed through a porcelain tube *heated to bright redness* it is almost wholly resolved into C and H, together with small quantities of ethylene and of tar containing naphthalene. Acetylene is also resolved into C and H by exploding a percussion-cap in it (Berthelot, *C. R.* 93, 613). Heated to dull redness in a bent glass tube standing over mercury it is gradually polymerised, forming: a very volatile liquid probably C_4H_6, benzene C_6H_6, styrene C_8H_8 (135°-160°), a liquid mixture (210°-250°) of naphthalene $C_{10}H_8$ and probably naphthalene hydride $C_{10}H_{10}$, a mixture of strongly fluorescent oils distilling at 250°-340°, retene distilling at 360° (Berthelot, *C. R.* 62, 905).—3. Mixed with excess of *hydrogen* over mercury, and in contact with platinum-black, acetylene is converted into ethane: $C_2H_2 + 2H_2 = C_2H_6$; by alkaline reducing agents, into ethylene, C_2H_4, *e.g.* by the action of zinc and aqueous ammonia on its copper compound (Berthelot).—4. With *oxidising agents*. Converted by $KMnO_4$ into oxalic acid, $C_2H_2O_4$, with formic and carbonic acids as secondary products (Berthelot, *C. R.* 74, 35).—5. Slowly absorbed by an ammoniacal *cupric solution*, and for the most part oxidised, a carbonaceous substance being at the same time deposited, together with a small quantity of the compound $C_2Cu_2H_2O$ (Berthelot, *A. Ch.* [4] 9, 422).—6. Passed with *phosgene*, $COCl_2$, through a red-hot tube, it is polymerised to benzene (Berthelot, *Bl.* [2] 13, 9).—7. With *chlorine*, either pure or mixed with other gases, acetylene sometimes detonates, yielding HCl and free carbon. Frequently, however, $C_2H_2Cl_2$ is formed with explosion; or this compound is formed at first, and then the mixture suddenly explodes (Berthelot, *Bl.* [2] 5, 191).—8. Acetylene passed into bromine under water forms $C_2H_2Br_4$ (*v. tetra*-BROMO-ETHANE) and a non-volatile solid, a polymeride of C_2HBr_3.—9. Acetylene passed over *iodine* moistened with alcohol forms $C_2H_2I_2$ (Sabanejeff, *A.* 178, 109, *v. di*-IODO-ETHYLENE).—10. Acetylene passed into a solution of ICl in HCl forms C_2H_2ICl (Plimpton, *C. J.* 41, 392, *v.* CHLORO-IODO-ETHYLENE).—11. With *nitrogen*. When a series of strong induction-sparks is passed through a mixture of acetylene and nitrogen, hydrocyanic acid is formed, $C_2H_2 + N_2 = 2HCN$. Carbon and hydrogen are at the same time separated, but this may be prevented by diluting the gaseous mixture with 10 vol. H (Berthelot, *C. R.* 77, 1011).—12. Passed with vapour of *hydrocyanic acid* through a red-hot tube acetylene yields a small quantity of picoline C_6H_7N, and probably homologues thereof (Ramsay, *Ph. M.* [5] 4, 241). 13. Strongly heated with *butylene* and *amylene* it forms $C_2H(C_4H_9)$ and $C_2H(C_5H_{11})$ (Prunier, *A. Ch.* [5], 17, 5).—14. Successive treatment with H_2SO_4 and water forms some stable sulphonic acid (Zeisel, *A.* 191, 366).—15. Converted into aldehyde by an aqueous solution of *mercuric bromide*, even in the cold (Kutscheroff, *B.* 14, 1540):

$$CH{\vdots}CH + H_2O = CH_2{:}CH.OH = CH_3.CHO.$$

16. $SbCl_5$ absorbs acetylene forming $C_2H_2SbCl_5$, which, on heating, splits up into $SbCl_3$ and $C_2H_2Cl_2$.—17. Conc. HBrAq at 100° forms a little bromo-ethylene (vinyl bromide).—18. Conc. HI

forms some iodo-ethylene and ethylidene iodide. 19. Passed through boiling *sulphur*, it forms some thiophene (V. Meyer, *B.* 16, 2176).

METALLIC DERIVATIVES.—*Sodium acetylene* C_2HNa, is formed, with evolution of hydrogen and small quantities of ethylene and ethane, when sodium is gently heated in acetylene. At a dull red heat disodium-acetylene C_2Na_2 is formed.—*Potassium* decomposes acetylene in like manner, but with greater violence; when melted in the gas it takes fire and is converted into C_2K_2, which is also formed when K is heated to dull redness on ethylene-gas. All these compounds are decomposed by water with explosive violence and reproduction of acetylene (Berthelot, *A.* 139, 150).

Calcium-acetylene C_2Ca is formed by strongly heating an alloy of zinc and calcium with charcoal. Decomposed by water into $Ca(OH)_2$ and acetylene (Wöhler, *A.* 121, 220).

Copper-acetylene $C_2Cu_2H_2O$. It may be looked upon as C_2Cu_2aq or as $HC{\vdots}C.Cu.Cu.OH$; in the latter case it may be called *cuproso-vinyl hydroxide.* Berthelot (*A.* 138, 315) considers it to be *cuproso-vinyl oxide* $(C_2HCu_2)_2O$. It constitutes the red precipitate formed on passing acetylene or coal-gas into an ammoniacal solution of cuprous chloride. In the dry state it explodes when struck or when heated to 100°–120°, leaving a velvety black powder containing copper and charcoal. Takes fire in contact with chlorine, bromine, or finely divided iodine. Its formation affords a very delicate test for acetylene, the presence of 0·005 mg. of that compound being thus recognisable. The formula above given for it is due to Blochmann (*A.* 173, 174). According to Berthelot (*Bl.* [2] 5, 191) when acetylene is passed into a conc. solution of cuprous chloride in KCl a yellow crystalline pp. of *cuproso-vinyl chloride* C_2HCu_2Cl is formed, corresponding bromides and iodides being formed in a similar way.

Silver acetylene $C_2Ag_2H_2O$, is formed on passing acetylene into an ammoniacal solution of silver nitrate, as a white or yellowish precipitate which, when dry, explodes even more easily than the copper-compound. The above formula, due to Blochmann, is that of argento-vinyl hydroxide, $CH{\vdots}C.Ag.Ag.OH$; Berthelot on the other hand regards the compound as the corresponding oxide $(C_2HAg_2)O$. The formulæ of Blochmann and Berthelot require 83·7 and 86·7 p.c. Ag respectively; Miasnikoff (A. 118, 332) finds 88 p.c. Ag in the pp., a result that has been confirmed by Plimpton, and agrees with the formula $C_2H_22Ag_2O$. Acetylene completely pps. the silver even from a neutral solution of $AgNO_3$; the pp. contains variable quantities of $AgNO_3$ (Plimpton). The *chloride* $CH{\vdots}C.Ag.Ag.Cl$, is prepared by passing acetylene into an ammoniacal solution of silver chloride (Berthelot). By agitating silver acetylene with a solution of iodine in ether, till the colour of the liquid disappears and then evaporating, yellow offensive-smelling crystals are formed, the vapour of which strongly attacks the eyes (Berend, *A.* 135, 257); Baeyer (*B.* 18, 2275) has shown that they are di-iodo-acetylene: $C_2Ag_2 + 2I_2 = C_2I_2 + 2AgI$.

Gold and Mercury Compounds.—In an ammoniacal solution of aurous thiosulphate, acetylene forms a yellow highly explosive precipitate, and in an alkaline solution of potassio-mercuric iodide a yellow pp.: C_2HHgI,H_2O, which explodes slightly when heated and yields acetylene when treated with acids (Bassett, *C. N.*, 19, 28). H. W.

Theoretical considerations.—The explosive character of acetylene is undoubtedly connected with the fact that its formation from C and H is attended with disappearance of heat (Berthelot). It has been suggested by Baeyer (*B.* 18, 2277) that this disappearance of heat may be due to the production of a strained condition owing to the alteration in the direction of the attraction between the two carbon atoms.

To represent his views in a mechanical model, he supposes four steel wires fixed to a ball and radiating from it in the direction of the angles of an inscribed tetrahedron. Such a ball represents a free atom of carbon; union of such atoms is represented by a wire of one ball being attached to, and in a straight line with, a wire of another ball. If two such balls be taken and three of the wires from one ball be fastened to three of the wires from another ball and then bent in such a way that all six wires are parallel, then the arrangement is in a strained condition, for the wires will readily fly apart, representing the explosion of acetylene. The angle between two adjacent wires in one of the balls just described is 109° 28′, which is very near the angle of a pentagon (108°); hence if five balls be placed at the angles of a pentagon, very little bending will be required to make a wire from each ball in a straight line with a wire from the next. The angles of a hexagon, of a square, and of an equilateral triangle, differ by 10½°, 19½°, and 49½° respectively from 109½°; these numbers ought therefore to indicate the relative stability of rings containing 6, 4, and 3 carbon atoms. As a matter of fact, closed rings of carbon atoms usually contain five or six atoms, while rings containing three, four, or seven atoms are almost unknown.

Haloid derivatives of acetylene *v.* BROMO-, CHLORO-, and IODO-, ACETYLENE, -ETHYLENE, and -ETHANE.

DIACETYLENE $HC{\vdots}C.C{\vdots}CH$. Gas of peculiar smell resembling dipropargyl. Formed by heating diacetylene-di-carboxylic acid with ammoniacal Cu_2Cl_2 solution. With ammoniacal Cu_2Cl_2 it gives a violet-red pp., with ammoniacal $AgNO_3$ a very explosive yellow pp. By the action of a solution of iodine upon the silver-compound di-iodo-di-acetylene is formed. (Baeyer, *B.* 18, 2272.)

ACETYLENE DI-BROMIDE *v.* DI-BROMO-ETHYLENE.

ACETYLENE TETRA-BROMIDE *v.* TETRA-BROMO-ETHANE.

ACETYLENE DI-BROMIDE DI-CARBOXYLIC ACID *v.* DI-BROMO-FUMARIC ACID.

ACETYLENE BROMO-IODIDE *v.* BROMO-IODO-ETHYLENE.

ACETYLENE CARBOXYLIC ACIDS
$CH{\vdots}C.CO_2H.$

Acetylene mono-carboxylic acid *v.* PROPIOLIC ACID.

Acetylene-di-carboxylic acid
$C_4H_2O_4$. *i.e.* $CO_2H.C{\vdots}C.CO_2H$.
Formed by treating di-bromo- or iso-di-bromo-succinic acid with alcoholic KOH (4 mols.) at

100° (Bandrowski, *B.* 10, 838). The yield is 75 per cent. of the theoretical (Baeyer, *B.* 18, 677).

Separates from water in efflorescent crystals, these contain aq., which they lose over H_2SO_4, and then crystallise from ether in thick four-sided tables. The hydrated acid is v. e. sol. water, alcohol or ether, but the dry acid is less soluble. The acid decomposes when melted.

Salts.—$Na_2C_4O_4$ 3½aq.: slender needles.—KHC_4O_4: small crystals, sl. sol. water.—$ZnC_4O_4$1½aq.—PbC_4O_4aq.—$CuC_4O_4$3aq.: blue plates, sl. sol. cold water (Bandrowski, *B.* 12, 2212).

Reactions.—1. The acid and its acid salts are converted, by *heating with water*, into propiolic acid: $CO_2H.C⋮C.CO_2H = CO_2H.C⋮CH + CO_2$.—2. *Sodium-amalgam* reduces it to succinic acid.—3. *Bromine* combines forming di-bromo-fumaric acid.—4. HCl, HBr, or HI combine readily forming chloro-, bromo-, or iodo-, fumaric acids.

Methyl ether Me_2A''. (197°). Colourless liquid (Bandrowski, *B.* 15, 2694).

Acetylene tetra-carboxylic acid, so called, *v.* Ethane tetra-carboxylic acid.

Di-acetylene di-carboxylic acid $C_6H_2O_4$aq. *i.e.* $CO_2H.C⋮C.C⋮C.CO_2H$ aq. Prepared by the action of a concentrated aqueous solution of potassic ferricyanide upon a cooled magma of the cuprous compound of sodium propiolate:

$$2CuC⋮C.CO_2Na + O_2 = 2CuO + (C⋮C.CO_2Na)_2.$$

Colourless [illegible] O_2 + H_2O = C [illegible] 121. 2201. 18 [illegible] needles or tables, v. sol. water, alcohol, or ether, v. sl. sol. benzene or benzoline. Turns brown at 100° and explodes very violently at c. 177°. Explodes also on percussion. Turned purple by light. Gives a brownish-red pp. with ammoniacal cuprous chloride.

Reactions.—1. *Sodium-amalgam* reduces it to hydro-muconic acid,

$$CO_2H.CH:CH.CH_2.CH_2.CO_2H,$$

and adipic acid, $CO_2H.CH_2.CH_2.CH_2.CH_2.CO_2H$; some propionic is formed at the same time.—2. *Zinc dust* and HCl also reduce it to adipic acid.

Ether.—Et_2A'' (184°) at 200 mm. An oil. Reduced by zinc dust and HCl to ethyl propiolate (Baeyer, *B.* 18, 678, 2269).

Tetra-acetylene di-carboxylic acid $C_{10}H_2O_4$ *i.e.* $CO_2H.C⋮C.C⋮C.C⋮C.C⋮C.CO_2H$.

Preparation.—An aqueous solution of the acid sodium salt of di-acetylene di-carboxylic acid is heated on the water-bath. Sodium di-acetylene mono-carboxylate, $H.C⋮C.C⋮C.CO_2Na$, is then formed, with evolution of CO_2; the cuprous compound of this salt, $Cu.C⋮C.C⋮C.CO_2Na$ (?), is then prepared and this is oxidised by potassic ferricyanide:

$$2CuC⋮C.C⋮C.CO_2Na + O_2 = 2CuO + (C⋮C.C⋮C.CO_2Na)_2$$

(Baeyer, *B.* 18, 2271). Tetra-acetylene di-carboxylic acid may be reduced to sebacic acid, $CO_2H.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CO_2H$, by sodium-amalgam.

Iodo-acetylene carboxylic acid *v.* Iodo-propiolic acid.

ACETYLENE DI-CHLORIDE *v.* Di-chloro-ethylene.

ACETYLENE TETRA-CHLORIDE *v.* Tetra-chloro-ethane.

ACETYLENE CHLORO-BROMIDE *v.* Chloro-bromo-ethylene.

ACETYLENE CHLORO-IODIDE *v.* Chloro-iodo-ethylene.

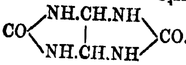
ACETYLENE HYDROCHLORIDE *v.* Chloro-ethylene.

ACETYLENE DI-HYDROCHLORIDE *v. di-*Chloro-ethane.

ACETYLENE IODIDE *v. di-*Iodo-ethylene.

ACETYLENE NAPHTHALENE *v.* Acenaphthylene.

ACETYLENE-UREA $C_4H_6N_4O_2$ *i.e.*



$$CO\begin{cases}NH.CH.NH\\ \quad\ \ |\\ NH.CH.NH\end{cases}CO.$$

Glycoluril.

S. ·094 at 17°. Formed as white needles when conc. HCl is added to a solution of glyoxal (1 pt.) and urea (2 pts.) and water (3 pts.). If the filtrate is evaporated, it deposits a yellow modification or impure form (Schiff, *A.* 189, 157; Böttinger, *B.* 11, 1787). Also formed by heating a mixture of tri-chloro-lactic acid, urea, and a little water at 100° (Pinner, *B.* 17, 1997). Formed when allantoïn is reduced with (1 p. c.) sodium-amalgam (Reineck, *A.* 131, 119; Widman, B. 19, 2477).

Properties.—White glistening prisms, sol. hot water. Gives a white flocculent pp. with $Hg(NO_3)_2$. Split up by boiling baryta water into urea and hydantoic acid—$C_4H_4Ag_2N_4O_2$.

ACETYL-ETHYL-PROPIONIC ACID *v.* Acetyl-valeric acid.

α-ACETYL-β-ETHYL-SUCCINIC ETHER $C_{12}H_{20}O_5$ *i.e.* CO_2Et [illegible] $.CHAc.CHEt.CO_2Et$ (263°) S.G. $_{17·5}$ 1·004. From aceto-acetic ether (68 g.), alcohol (120 g.), sodium (12 g.) and α-bromo-butyric ether (102 g.) (L. T. Thorne, *C. J.* 39, 336; S. Young, *C. J.* 43, 172).

Reactions.—1. Decomposed by *potash* (2 pts.) and water (1 pt.) into acetic and ethyl-succinic acid.—2. Decomposed by potash (1 pt.) and water (20 pts.) into salts of CO_2 and β-acetyl-α-ethyl-propionic acid (*v.* Acetyl-valeric acid).—3. With NaOEt and MeI it gives α-acetyl-α-methyl-β-ethyl-succinic ether (*q.v.*)—4. The ether (3 pts.) boiled with conc. HCl (2 pts.) and water (4 pts.) for 2 days forms β-acetyl-α-ethyl-propionic acid, which may be extracted by ether, and a crystalline acid, *Ketolactonic acid* (*q.v.*) which remains in the water. Ethyl-succinic acid is also formed.—5. When *heated*, it partly splits up into alcohol and ketolactonic acid.

α-ACETYL-α-ETHYL-SUCCINIC ETHER $C_{12}H_{20}O_5$ *i.e.* $CO_2Et.CAcEt.CH_2.CO_2Et$ (264°). From sodium acetyl-succinic ether and EtI (Huggenberg, *A.* 192, 146). Conc. alcoholic KOH converts it into ethyl-succinic acid.

DI-ACETYL-FUMARIC ETHER $C_{12}H_{16}O_6$ *i.e.* $CO_2Et.CAc:CAc.CO_2Et$ [96°]. Formed by the action of iodine (1 mol.) upon di-sodio-di-acetyl-succinic ether (1 mol.) suspended in ether:

$$CO_2Et.CNaAc.CNaAc.CO_2Et + I_2 = CO_2Et.CAc:CAc.CO_2Et + 2NaI.$$

Long silky needles (Just, *B.* 18, 2636).

α-ACETYL-GLUTARIC ETHER $C_{11}H_{18}O_5$ *i.e.* $CO_2Et.CHAc.CH_2.CH_2CO_2Et$ (272°) S.G. $\frac{14·1}{17·5}$ 1·0505. From aceto-acetic ether, β-iodo-propionic ether, benzene, and sodium (Wislicenus a. Limpach, *A.* 192, 130). Conc. alcoholic KOH splits it into acetic and glutaric acids. Boiling HCl forms CO_2 and γ-acetyl-butyric acid.

β-Acetyl-glutaric acid $CHAc(CH_2.CO_2H)_2$. [109°]. Formed by heating α-carboxy-β-acetyl-glutaric acid (from chloro-acetyl-propionic ether

and sodio-malonic ether) (Conrad a. Guthzeit, *B.* 19, 44).—AgA′.

Di-acetyl-glutaric ether $C_{13}H_{20}O_6$ *i.e.*
$CO_2Et.CHAc.CHAc.CH_2.CO_2Et$ or
$CO_2Et.CHAc.CH_2.CO.CH_2.CH_2CO_2Et$.
(c. 245) at 140 mm. From bromo-acetyl-propionic ether, $CH_3.CO.CHBr.CH_2.CO_2Et$ and sodio-aceto-acetic ether (Knorr, *B.* 19, 47). Ammonia in HOAc converts it into di-methyl-pyrryl-acetic carboxylic ether

$$HN\begin{cases}CMe{:}C.CH_2.CO_2Et\\ \quad\quad\ \ |\\ CMe{:}C.CO_2Et\end{cases}$$

ACETYL-GLYCOCOLL *v.* Aceturic acid.

ACETYLIDE *v.* Acetyl chloride, *Reaction* 11.

ACETYL IODIDE C_2H_3OI or AcI (108°) (G.); (105°) (C.). S. G. ^{17} 1·98 (O.). Prepared by the action of P and I upon acetic anhydride (Guthrie, *P. M.* [4] (1857) 14, 183) or on KOAc (Cahours (1857) *C. R.* 44, 1253). Also by heating acetyl chloride with $CaI_2 3\frac{1}{2}aq$ at 75°. The water of crystallisation has little saponifying effect (Spindler, *A.* 231, 272).

Properties.—Liquid. Fumes in air; pungent smell; sour taste. Water quickly forms HI and HOAc; alcohol forms EtOAc. Decomposed by zinc or sodium at 15°, and by mercury in sunshine, forming HgI (G.). H. W.

ACETYL-MALONIC ETHER $C_9H_{14}O_5$ *i.e.* $CH_3.CO.CH(CO_2Et)_2$ (239°–245°) S.G. ^{24} 1·080. From aceto-acetic ether, alcoholic NaOEt and $ClCO_2Et$. (Ehrlich, *B.* 7, 892; Conrad, *A.* 214, 35). Aqueous NaOH decomposes it into acetone, CO_2, alcohol, and acetic acid.

ACETYL-METHYL-ACETO-ACETIC ETHER *v.* Aceto-acetic acid.

ACETYL-TETRA-METHYLENE *v.* Tetra-methylene methyl ketone.

ACETYL-TETRA-METHYLENE CARBOXYLIC ACID, so called, *v.* Acetyl-Butyl Alcohol.

ACETYL-TRI-METHYLENE *v.* *tri*-Methylene methyl ketone.

α-ACETYL-α-METHYL-β-ETHYL - SUCCINIC ETHER
$C_{13}H_{22}O_5$ *i.e.* $CH_3.CO.CMe(CO_2Et).CHEt.CO_2Et$. From α-acetyl-β-ethyl-succinic ether, NaOEt and MeI (S. Young, *C. J.* 43, 178). Boiled with dilute HCl it forms a γ-oxy-octoic acid (*q. v.*) and methyl-ethyl-succinic acid.

ACETYL-METHYL-TRI-METHYLENE CARBOXYLIC ACID *v.* *propylene-aceto-acetic acid* under Aceto-acetic acid.

α-ACETYL-α-METHYL-GLUTARIC ACID
$C_{12}H_{20}O_5$ *i.e.* $CO_2Et.CMeAc.CH_2.CH_2.CO_2Et$. (281°); S.G. $\frac{20}{17.5}$ 1·043. From β-iodo-propionic ether and sodium methyl-aceto-acetic ether (Wislicenus a. Limpach, *A.* 192, 133). With conc. alcoholic KOH it gives acetic and α-methyl-glutaric acids.

ACETYL-METHYL-PYROTARTARIC ETHER *v.* Acetyl-di-methyl-succinic ether.

α-ACETYL-α-METHYL-SUCCINIC ETHER $C_{11}H_{18}O_5$ *i.e.* $CO_2Et.CMeAc.CH_2.CO_2Et$ (c. 263°) S.G. 1·067. From sodium acetyl-succinic ether and MeI (Kressner, *A.* 192, 135). Decomposed by conc. alcoholic KOH with formation of acetic and pyro-tartaric acids. Baryta-water or HCl produce CO_2 and β-acetyl-butyric acid (*q. v.*).

α-Acetyl-β-methyl-succinic ether
$CO_2Et.CMeH.CAcH.CO_2Et$ (c. 258°) (C.); (c. 263°) (Gottstein, *A.* 216, 31); (c. 227°) at 165 mm. (Bischoff, *A.* 206, 320). S.G. $\frac{27}{17.5}$ 1·061. Formed by action of α-bromo-propionic ether on sodium aceto-acetic ether (Conrad, *A.* 188, 226). Decomposed by conc. KOH into alcohol, pyrotartaric acid, acetic acid, CO_2, and β-acetyl-iso-butyric acid; baryta-water (8 p.c.), or HCl, produce only CO_2 and β-acetyl-iso-butyric acid.

α-Acetyl-α-β-di-methyl-succinic Ether
$C_{12}H_{20}O_5$ *i.e.* $CO_2Et.CMeAc.CHMe.CO_2Et$ (270°–272°) S.G. $\frac{27}{17.5}$ 1·057. Formed from α-acetyl-β-methyl-succinic ether, sodium, and MeI (Hardtmuth, *A.* 192, 142). Boiling conc. alcoholic KOH converts it into acetic and α-β-di-methyl-succinic acids.

ACETYL OXIDE and Peroxide *v.* Acetic oxide.

ACETYL-OXY-COMPOUNDS *v.* Oxy-compounds.

ACETYL-PHENYLENE-DIAMINE *v.* Phenylene-di-amine.

β-ACETYL-α-PHENYL-PROPIONIC ACID $C_{11}H_{12}O_3$ *i.e.* $CO_2H.CHPh.CH_2Ac$. *Benzyl-acetone-γ-carboxylic acid.* [126°]. Prepared by boiling the ethers of acetyl-phenyl-succinic acid with baryta-water or dilute HCl. Plates. V. sol. alcohol or ether. On reduction with sodium-amalgam it gives the lactone of γ-oxy-α-phenyl-valeric acid, $CH_3.CH(OH).CH_2.CHPh.CO_2H$.

Salts.—$^{*}A'_2Zn$: long white needles.—$^{*}AgA'$: white pp.—$^{*}CuA'_2$: green; insol. water, sol. alcohol.—$^{*}CuA'_2$ and $^{*}BaA'_2$ are easily soluble (Weltner, *B.* 17, 72).

ACETYL-PHENYL-SUCCINIC ACID $C_{12}H_{12}O_5$ *i.e.* $CO_2H.CHPh.CHAc.CO_2H$. [121°]. Formed by saponification of the di-ethyl-ether, which is prepared by the action of phenyl-bromo-acetic ether on sodio-acet-acetic ether. Large plates. (Weltner, *B.* 17, 71.) When boiled with dilute hydrochloric acid or baryta water, it splits off CO_2, giving acetyl-phenyl-propionic acid,

$$C_6H_5.CH(CO_2H).CH_2.CO.CH_3.$$

—$A''K_2$ easily soluble glistening needles.

(α)-*Mono-ethyl-ether* $C_{14}H_{16}O_5$ *i.e.* $CO_2Et.CHPh.CHAc.CO_2H$. [133°]. Formed together with the di-ethyl ether by the action of phenyl-brom-acetic ether upon sodio-aceto-acetic ether. On heating, it evolves CO_2, giving phenyl-levulic ether (Weltner, *B.* 18, 790).

(β)-*Mono-ethyl-ether* $C_{14}H_{16}O_5$ *i.e.* $CO_2H.CHPh.CHAc.CO_2Et$. [128°]. White pearly plates; easily soluble in alcohol and ether. Formed by the action of sodium phenyl-bromo-acetate upon sodio-aceto-acetic ether. By heating to 200° CO_2 is not split off. Boiled with baryta, it yields phenyl-levulic acid. It is reduced by sodium amalgam to α-phenyl-valero-γ-lactone-β-carboxylic acid:

$$\begin{array}{l}CHPh.CO.O\\ |\qquad\qquad\ |\\ CH(CO_2H).CH.CH_3.\end{array}$$

With alcoholic NH_3 it yields $C_{12}H_{12}N_2O_2$.

Phenyl-hydrazide $C_{22}H_{26}N_2O_4$ [149°], plates.

Di-ethyl-ether $A''Et_2$ [76°], plates.

DI-ACETYL-PHOSPHORIC ACID $C_4H_9PO_7$ *i.e.* $H_3Ac_2PO_5$. A viscid liquid, formed by the action of AcCl on Ag_3PO_4 (Carius a. Kämmerer, *A.* 131, 170). Boiling water decomposes it into acetic and ortho-phosphoric acids. It forms a calcium salt, $CaHAc_2PO_5 2aq$, crystallising in needles.

ACETYL-PIPER - PROPYL - ALCEINE *v.* Oxypropyl-piperidine.

ACETYL-PROPIONIC ACIDS $C_5H_8O_3$.

α-Acetyl-propionic Acid $CH_3.CHAc.CO_2H$, *v.* *Methyl-aceto-acetic acid* under ACETO-ACETIC ACID.

β-Acetyl-propionic Acid $CH_3.CO.CH_2.CH_2.CO_2H$. *Levulic acid.* [33·5°]. (239°). S.G. ^{15} 1·135. μ_D 1·443 at 15°. R_∞ 45·3.

Formation.—1. By boiling acetyl-succinic ether with dilute HCl (Conrad, *B.* 11, 2177). 2. By boiling the following substances with very dilute H_2SO_4: Levulose, inulin, cane sugar (Grote a. Tollens, *A.* 175, 181), gum arabic, or caragheen moss (Bente, *B.* 9, 1157). Filter paper and deal shavings give a small quantity. Small quantities may also be got from glucose, milk-sugar, and galactose, by heating with aqueous HCl.

Preparation.—Cane-sugar (1500 g.) is heated for 20 hours with water (1500 g.) and H_2SO_4 (150 g.), with occasional shaking. A large quantity of humic substance separates. The thick liquid is filtered under pressure, mixed with $CaCO_3$ (150 g.), and the whole evaporated (till it weighs 1500 g.). The liquid is again filtered, mixed with H_2SO_4 (50 g.) and shaken with ether. After evaporating the ether, the levulic acid (100 g.) is rectified (Grote, Kehrer a. Tollens, *A.* 206, 210). If glucose be used, the yield is not so good, and it is then better to use HCl (*v.* Conrad a. Guthzeit, *B.* 18, 442). Formic acid is also formed in these reactions:

$$C_6H_{12}O_6 = C_5H_8O_3 + CH_2O_2 + H_2O.$$

Properties.—Deliquescent trimetric plates. V. sol. water, alcohol or ether. On distillation it produces (α)- and (β)-angelico-lactone, and also acetic acid, and another acid possibly $C_{10}H_{10}O_3$ [208°] (Wolff, *A.* 229, 260). Not attacked by bromine in the cold.

Reactions.—1. *Chromic mixture* produces CO_2 and acetic acid.—2. Dilute HNO_3 gives succinic, oxalic, acetic, and hydrocyanic acids (Tollens, *B.* 12, 334; *A.* 206, 257).—3. Reduced, by P and HIAq at 150°-200°, or by sodium-amalgam in acid solution, to *n*-valeric acid.—4. In alkaline solution *sodium amalgam* produces γ-oxy-valeric acid (*q. v.*). 5. Gives the iodoform reaction with NaOH and I.—6. Reacts with hydroxylamine, forming an oxim.

Salts.—$CaA'_2$2aq: minute needles.—AgA': six-sided tables.—NaA': minute needles.—CuA'_2 (at 150°): bluish-green flat needles or prisms. Barium, magnesium, and cadmium salts are gummy.

Ethers.—MeA'. (191·5°). S.G. $\frac{0}{0}$ 1·0684. μ_D 1·4216 at 15°. R_∞ 52·2.—EtA'. (200·5°) (G. K. a. T.) (204°) (W.). S.G. $\frac{0}{0}$ 1·0325. μ_D 1·421. R_∞ 60·2.—PrA'. (215·5°). S.G. $\frac{0}{0}$ 1·0103. μ_D 1·4246. R_∞ 69·5.

Amide.—$C_5H_7O.NH_2$. [108°]. From ethyl levulate and alcoholic NH_3 or from (α)-angelico-lactone (*q. v.*) and aqueous or alcoholic ammonia. Six-sided tables (from alcohol-chloroform, Wolff, *A.* 229, 260).

References.—See also BROMO- and CHLORO-ACETYL-PROPIONIC ACIDS.

ACETYL-PROPYL ALCOHOL $C_5H_{10}O_2$ *i.e.* $CH_3.CO.CH_2.CH_2.CH_2OH$. *Methyl γ-oxy-propyl ketone.* A colourless liquid, soluble in water, formed by boiling bromo-ethyl-aceto-acetic ether $BrCH_2CH_2.CHAc.CO_2Et$ with dilute HCl. It readily reduces ammoniacal $AgNO_3$Aq but not Fehling's solution. It is converted by heat into an anhydride. *Sodium-amalgam* reduces it to ω-γ-di-oxy-*n*-pentane, $CH_3.CH(OH).CH_2.CH_2.CH_2OH$ (Perkin jun. a. Freer, *B.* 19, 2566).

ACETYL-PYRO-PHOSPHORIC ACID.

The barium salt, $BaHAcP_2O_7$2aq, is got as a crystalline pp., sl. sol. dilute acids, by adding aqueous hydrogen peroxide to a solution of barium acetyl-pyrophosphite (Menschutkin, *A.* 136, 254).

ACETYL - PYRO - PHOSPHOROUS ACID, $AcH_3P_2O_5$2aq, is got by heating AcCl with H_3PO_3 at 50° (Menschutkin, *A.* 133, 317). Crystalline mass.

Salts.—$K_2HAcP_2O_5$2½aq: slightly sol. water. $BaHAcP_2O_5$: insol. water.—$PbHAcP_2O_5$: insol. water.

ACETYL-PYRO-TARTARIC ACID *v.* ACETYL-METHYL-SUCCINIC ACID.

ACETYL-PYRROL *v.* PYRROL.

Pseudo-acetyl-pyrrol *v.* PYRRYL METHYL KETONE.

ACETYL-SUCCINIC ETHER $C_{10}H_{16}O_5$ *i.e.* $CO_2Et.CHAc.CH_2.CO_2Et$. (c. 255°); (210° i. V.) at 330 mm. S.G. $\frac{21}{17\cdot5}$ 1·079; $\frac{15}{15}$ 1·088; $\frac{25}{25}$ 1·080. M.M. 10·343 (Perkin, *C. J.* 45, 517). Formed by action of chloro-acetic ether upon sodium aceto-acetic ether (Conrad, *A.* 188, 218). Oil. Sol. alcohol or ether. Gives no colour with Fe_2Cl_6. Conc. alcoholic KOH splits it into acetic and succinic acids; boiling baryta-water forms β-acetyl-propionic ether and CO_2.

Phenyl-hydrazide $C_{16}H_{22}N_2O_4$. [80°]. At 150° it splits off EtOH and gives methyl-oxy-quinizyl-acetic ether (Knorr a. Blank, *B.* 17, 2051).

Di-aceto-succinic Ether $C_{12}H_{18}O_6$ *i.e.* $CO_2Et.CHAc.CHAc.CO_2Et$. [79°].

Sodium acetacetic ether is treated in ethereal solution with iodine (Rügheimer, *B.* 7, 892):

$$2CO_2Et.CHNa.CO.CH_3 + I_2 = (CO_2Et.CHAc)_2 + 2NaI.$$

The ethylic di-aceto-succinate crystallises from the ether (Harrow, *C. J.* 33, 427). It forms trimetric tables, v. e. sol. alcohol, ether, or benzene.

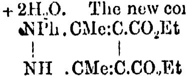
Reaction.—1. Boiled with dilute H_2SO_4 (1 : 10) it gives off CO_2 and forms pyro-tritaric or uvic ether $C_9H_{12}O_3$ and carbo-pyro-tritaric ether $C_8H_7O_5Et$.—2. *Hydroxylamine* forms a di-oxim (needles; Münchmeyer, *B.* 19, 1849), and a neutral ether $C_{12}H_{17}NO_5$ (Knorr, *B.* 18, 1568).—3. *Ammonia* forms di-methyl-pyrrol di-carboxylic ether $C_4HMe_2N(CO_2Et)_2$ or

$$NH\left\langle\begin{array}{l}CMe{:}C.CO_2Et\\ \qquad\ \ |\\ CMe{:}C.CO_2Et.\end{array}\right.$$

Primary bases act in a similar manner, thus methylamine forms

$$NMe\left\langle\begin{array}{l}CMe{:}C.CO_2Et\\ \qquad\ \ |\\ CMe{:}C.CO_2Et\end{array}\right.$$

(Knorr, *B.* 18, 299). 4. *Phenyl-hydrazine* acts in a similar way: $C_{12}H_{18}O_6 + N_2H_3C_6H_5 = C_{18}H_{22}N_2O_4 + 2H_2O$. The new compound, which may be



$$\begin{array}{l}NPh.CMe{:}C.CO_2Et\\ \ \ |\qquad\quad\ \ |\\ NH\ \ .CMe{:}C.CO_2Et\end{array}$$

is called phenyl-di-methyl-pyridazine di-carboxylic ether. It contains H_2O less than the mono-phenyl-hydrazide of di-acetyl-succinic ether, $CO_2Et.CH(CMe{:}N_2PhH).CHAc.CO_2Et$ (Knorr, *B.* 17, 2058; 18, 305). It crystallises in prisms, [127°] (from benzoline). See also PHENYL-HYDRAZINE.

ACETYL SULPHIDE $C_4H_6O_2S$ or Ac_2S. *Di-acetyl sulphide, Thio-acetic anhydride* (120°).

Preparation.—1. From Ac_2O and P_2S_5 (Kekulé, *A.* 90, 312). Yield 10 p.c.—2. From AcCl and K_2S.—3. By distilling PbSAc.

Properties.—An oil, slowly decomposed by water into HOAc and HSAc.

Di-acetyl Di-sulphide $C_4H_6O_2S_2$ or Ac_2S_2 [21°].

Formation.—1. From KSAc and I (Kekulé a. Linnemann, *A.* 123, 279).–2. From BaO_2 and Ac_2S in ethereal solution (Beckmann, *J. pr.* 125, 465): $2Ac_2S + BaO_2 = Ac_2S_2 + Ba(OAc)_2$.—3. By electrolysis of thio-acetic acid (Bunge, *B.* 3, 297).

Properties.—Crystalline. Insol. water, v. sol. alcohol or CS_2. Decomposed by warm water or by alkalis forming thio-acetic acid and sulphur. Decomposed by distillation.

ACETYL SULPHOCYANIDE C_3H_3NSO or $CH_3.CO.S.Cy$. (133°). S.G. ^{16} 1·151. From AcCl and lead sulphocyanide (Miquel, *A.Ch.* [5] 11, 295). Pungent liquid. Decomposed by water into HOAc and HSCN. Forms with NH_3 in ethereal solution a non-volatile liquid which dissolves in water and gives a red colour with Fe_2Cl_6.

ACETYL-THIO-UREA *v.* THIO-UREA.

ACETYL-TOLYLENE-DI-AMINE *v.* TOLYLENE-DI-AMINE.

ACETYL-UREA *v.* UREA.

ACETYL-VALERIC ACID $C_7H_{12}O_3$.

α-Acetyl-*n*-valeric Acid *v. n-propyl-aceto-acetic acid* under ACETO-ACETIC ACID.

α-Acetyl-*s*-*iso*-valeric Acid *v. iso-propyl-aceto-acetic acid* under ACETO-ACETIC ACID.

α-Acetyl-*u*-*iso*-valeric Acid *v. methyl-ethyl-aceto-acetic* acid under ACETO-ACETIC ACID.

β-Acetyl-*u*-*iso*-valeric Acid

$CH_2Ac.CHEt.CO_2H$.

(250°–252°). Got by boiling α-acetyl-β-ethyl-succinic ether (*q. v.*) with dilute KOH (Thorne, *C.J.* 39, 340). Liquid, miscible with water, alcohol, and ether. Turns brown in air. It is gradually decomposed by heat into H_2O and an oil $C_7H_{10}O_2$ (219°). S.G. $\frac{20}{20}$ 1·0221.

Reaction.—HNO_3 oxidises it to ethyl-succinic acid.

Salts.—Gummy, soluble in water.

Ether.—EtA′ (224°–226°). Lighter than water.

ACHILLEA.—The Iva plant (*A. Moschata*) has been chemically examined by v. Planta-Reichenau (*A.* 155, 145), who has extracted from it the following substances: 1. Ivaïn $C_{24}H_{42}O_5$, obtained by distilling the dried herb (freed from the roots) with water to remove volatile oil, exhausting the dried residue with absolute alcohol, precipitating with lead acetate, removing excess of lead with H_2S, and exhausting the evaporated residue with acetic acid to remove achillein and moschatin. Ivaïn then remains as a dark yellow resinous mass, insoluble in water, easily soluble in alcohol, yielding an intensely bitter solution. — 2. Achilleïn $C_{20}H_{38}N_2O_{15}$ and Moschatin $C_{21}H_{27}NO_7$ are obtained by distilling the herb, gathered before flowering, with water, exhausting the concentrated filtrate with absolute alcohol, evaporating off the alcohol and adding water, which throws down moschatin; and on treating the liquid filtered therefrom with $Pb(OH)_2$, again filtering, removing lead with H_2S, and evaporating, Achilleïn remains as a brown-red mass, very soluble in water, less readily in alcohol, insoluble in ether; very bitter; not precipitated by lead salts. Resolved by prolonged boiling with dilute sulphuric acid into sugar and achilletin $C_{11}H_{17}NO_4$, a dark-brown powder, insoluble in water, very slightly soluble in alcohol; not bitter. Moschatin $C_{21}H_{27}NO_7$ is pulverulent, nearly insoluble in water, somewhat soluble in absolute alcohol; tastes bitter.

A. Ageratum, growing in Italy and Provence, yields an essential oil boiling at 165°–182°; sp. gr. 0·849 at 14° (De Luca, *J. Ph.* [4] 18, 105).

ACHROO-DEXTRIN *v.* DEXTRIN and STARCH.

ACIDIMETRY. The estimation of acids by volumetric methods. *V.* ANALYSIS.

ACID-FORMING OXIDES. Same as ANHYDRIDES (*q. v.*).

ACIDS.—*Salts of hydrogen.* The word *acid* (*ac*, sharp; *acere*, to be sour; compare *acetum*, vinegar, ὀξύς, ὄξος) was originally loosely applied to all sour liquids. The term cannot now be accurately defined; but it may be stated generally that an acid is a compound of hydrogen, which, when mixed with, or dissolved in, water, is capable of exchanging the whole, or a portion, of the hydrogen it contains for a metal, with simultaneous formation of water, by the action on the aqueous solution of the acid of a metallic oxide or hydroxide.

HISTORY.—The corrosive action of acids, and their power of dissolving metals and other substances have been known from early times. Thus Geber, who lived during the eighth century, was acquainted with impure nitric and sulphuric acids, and described them under the name *aquæ dissolutivæ*. Paracelsus (16th century), from whom the school of Iatro-chemists sprang, held that the human body in health consisted of certain acid and alkaline principles which balanced each other, and that disease was due to a preponderance of one or other of these principles. He was the first to propound a theory to account for the properties common to all acids; he supposed that they all contained an acid principle, which conferred taste and solubility on all substances into which it entered. This theory was accepted by Becher (17th century), who named the acid principle *acidum primogenium*; and he added that it consisted of a compound of earth and water, both of which he believed to be elements. The distinctive properties of acids:—their solvent power, their power of changing the colour of certain vegetable tinctures, and the fact that they form neutral bodies with alkalis;—were catalogued by Boyle (17th century). Stahl, in 1723, adopted Becher's theory, and endeavoured to prove that while acids were the bases of all saline bodies, the principle of all acids was sulphuric acid. Stahl's view continued to find supporters for a long time, but its defects were at length perceived. Many of the supporters of the phlogistic theory held that inorganic acids, such as sulphuric and phosphoric acids, were simple substances; and that by their combinations with phlogiston they gave rise to bodies such as sulphur and phosphorus, which were then regarded as compounds, but which we now know to be elements. After the discovery of oxygen by Priestley and Scheele, Lavoisier, in naming that element from ὀξύς (acid) and γεννάω (I produce), generalised the facts discovered by him, that many acid bodies are produced by the union of 'combustibles' with oxygen; and although it was pointed out by Berthollet in 1789 that sulphydric and prussic acids contain no oxygen, the view of Lavoisier generally prevailed until the researches of Davy, and of Gay-Lussac and Thenard, on muriatic and oxymuriatic acids (hydrochloric acid and chlorine) in 1810, and the discovery and examination of hydriodic acid, and the investigation of prussic acid by Gay-Lussac in 1814 and 1815, compelled chemists to recognise the existence of true acids containing no oxygen, and led to a distinction being drawn between acids which contained oxygen, and those which did not.

Lavoisier also regarded acids as binary oxygenated compounds; and he supposed that the water which must be present in order that an acid shall react on other bodies merely played the part of a solvent. This view was supported and extended by Berzelius, who taught that certain oxides are capable of uniting with each other to form 'ternary' compounds or salts, and that these salts are decomposed by electrolysis into their 'binary' constituents, which are an acid and a base. Berzelius therefore applied the term electronegative to that oxide which appeared at the positive electrode on electrolysis of a salt, and the term electropositive to that oxide which separated at the negative electrode. The negative oxides he classed as acids, and the positive oxides as bases. This theory ignored the fact that water is associated with these oxides in their various reactions; and, moreover, it overlooked the evident analogy between acids containing oxygen and acids containing no oxygen, but formed by the union of the halogens, or haloid groups, with hydrogen. To restore this analogy, Davy proposed to abandon the old view that acids were compounds of certain elements with oxygen, and suggested that all acids, whether they contained oxygen or not, should be considered as compounds of hydrogen. Dulong supported Davy's view, and extended it; he regarded acids as compounds of hydrogen with elements such as Cl, I, S; or with radicles such as CN, NO_3, SO_4. As it was at that time supposed that such radicles were capable of separate existence, and as Dulong's hypothesis involved the creation of a large number of hypothetical substances, this hypothesis did not meet with general support. It was reserved for Gerhardt, led by a study of organic substances, to prove that most acids, when vaporised, do not separate into an oxide and water, but pass into the state of vapour as a whole. From this it followed that hydrogen, replaceable by metals, must be a constituent of all true acids.

Characteristic features of acids.—Bodies possessing properties corresponding with the definition of an acid given at the beginning of this article always contain hydrogen in intimate combination with one or more of the following elements; fluorine, chlorine, bromine, iodine, oxygen, sulphur, selenion, tellurium, or certain groups of elements (*e.g.* cyanogen) of which carbon is one (comp. Acids, Organic, p. 53). It is true that water is not accounted an acid, nor is it usual to include hydrogen dioxide among the acids; yet if the definition of acid were strictly applied hydrogen dioxide would find a place in this class, for it has an acid reaction with test paper, and on addition, for example, of barium hydroxide to a solution of it in water, the reaction characteristic of acids takes place;—

$$Ba(OH)_2.8H_2O + H_2O_2 = BaO_2.8H_2O + 2H_2O.$$

Again, the reactions of hydrogen sulphide, selenide, and telluride, with alkalis, would lead to their inclusion among acids. The name acid must also be applied to most compounds of hydrogen and one of the elements above mentioned with a third element. The following examples will illustrate the definition given :—

Simple.	Compound.
HF.	$HBF_4 = HF.BF_3$.
HCl.	$H_2PtCl_6 = 2HCl.PtCl_4$.
HCN.	$H_4Fe(CN)_6 = 4HCN.Fe(CN)_2$.
(H_2O.)	$H_2SO_4 = H_2O.SO_3$.
H_2S.	$H_2CS_3 = H_2S.CS_2$.
&c.	&c.

Such bodies as H_2ZnO_2 ($Zn(OH)_2$), and H_3AlO_3 ($Al(OH)_3$), may be classed either among acids or basic hydroxides, inasmuch as they possess the characteristics of both classes.

Among the compounds of carbon the acids form an important class. The formulæ of these compounds may be supposed to be derived from the formula either of formic acid, or of carbonic acid. If formic acid be taken as the type, then most acids containing carbon may be viewed as substituted formic acid; thus :—

$HCOOH$.	CH_3COOH.	$C_2H_4(COOH)_2$.
Formic acid.	Acetic acid.	Succinic acid.

$C_3H_4(OH)(COOH)_3$.
Citric acid.

It is to be noticed that in two cases more than one molecule of formic acid is employed; and that succinic acid, by this view, is to be regarded as two molecules of formic acid, in which two atoms of hydrogen are replaced by the group C_2H_4; while citric acid is derived from three molecules of formic acid by replacement of three atoms of hydrogen by the group $C_3H_4(OH)$. The carboxylic acids may be similarly derived from carbonic acid ($CO(OH)_2$), if one hydroxyl group be regarded as replaced by an alkyl or similar group. But it is clear that unless this view of the composition of carbon acids helps to render prominent the actual relations existing between these compounds, it can be of no value. In this view of the constitution of carbon acids these compounds are all represented as containing the characteristic group CO.OH; this group has been named 'carboxyl,' a word derived from 'carbonyl,' CO, and 'hydroxyl,' OH, and implying the presence of these two groups. That most of the acids of carbon contain the group CO.OH is rendered probable by the following considerations: when one of these acids is distilled with phosphorous chloride, PCl_3, the hydroxyl group is replaced by chlorine, thus;

$$3CH_3.CO.OH + 2PCl_3 = 3CH_3CO.Cl + P_2O_3 + 3HCl.$$

And on warming such a chloride with water the acid is re-formed;

$$CH_3.CO.Cl + H_2O = CH_3CO.OH + HCl.$$

It is thus proved that oxygen and hydrogen can be removed together from the acid molecule. Moreover, on treatment of the acid chloride with nascent hydrogen, the chlorine is replaced by hydrogen, and an aldehyde is produced, thus;

$$CH_3COCl + 2H = CH_3CHO + HCl.$$

This aldehyde, when treated with phosphoric chloride, PCl_5, exchanges its oxygen for two atoms of chlorine, thus;

$$CH_3CHO + PCl_5 = CH_3.CHCl_2 + POCl_3.$$

It is therefore inferred that the atom of oxygen replaced by chlorine in the last reaction is differently related to the other atoms in the molecule from that atom of oxygen which is replaceable by chlorine only when hydrogen accompanies it. The formula of the characteristic group, CO.OH, thus appears reasonable.

But there are many compounds of carbon exhibiting the property of exchanging hydrogen for a metal by the action of an oxide or hydroxide, which do not contain the carboxyl group. Among these compounds may be mentioned bodies such as ethane sulphonic acid, $C_2H_5.HSO_3$, and ethane phosphonic acid, $C_2H_5.H_2PO_3$, &c.; many of these bodies may be regarded as acid ethereal salts of inorganic acids. There are, however, others which, in spite of their acid properties, it is not usual to name acids, although many of them might be legitimately included in this class. For instance the mercaptans, of which ethyl hydrosulphide may be chosen as an example, react with oxides or hydroxides in a similar manner to sulphydric acid, H_2S, thus, $C_2H_5.SH + KOH = C_2H_5SK + H_2O$: and the corresponding selenion and tellurium compounds exhibit a like behaviour. Again, many of the nitro-compounds of the alkyl radicles have the power of exchanging hydrogen for a metal, under the usual limitations, as for example:

$$CH_3NO_2 + KOH = CH_2KNO_2. + H_2O :—$$

$C(NO_2)_3H$ yields $C(NO_2)_3K$, etc. Hydroxyquinones, such as alizarin $C_{14}H_8O_2(OH)_2$, act as dibasic acids, forming compounds such as $C_{14}H_8O_2(OK)_2$; phenols, and their substitution derivatives, also yield metallic derivatives, *e.g.* sodium phenate C_6H_5ONa, sodium picrate $C_6H_2(NO_2)_3$ ONa. On comparing such compounds with each other, and with other acids, the following deductions may be drawn:—(1.) That a powerfully electro-negative element such as fluorine, chlorine, bromine, or iodine, confers acid properties on its compound with hydrogen. (2.) That in compounds of elements exhibiting less markedly electronegative properties than the halogens, the presence of an electronegative element is necessary to the development of acid character. This may be seen from the following considerations. Hydrocarbons, such as methane, CH_4, exhibit no acid properties; if an atom of an electronegative element such as oxygen or sulphur is introduced into the molecule in place of one or more atoms of hydrogen, the compound so formed, although not generally a true acid, yet exhibits a more or less acidic character. Thus, methylic alcohol, CH_3OH, forms metallic derivatives (CH_3ONa, &c.) by the action on it of strongly positive metals; but as such compounds are decomposed by water, they cannot be formed in presence of that substance. Here, however, we may note that phenol, C_6H_5OH, and similar compounds, reacts with the hydroxides of strongly positive metals to form metallic derivatives which, although comparatively unstable, are nevertheless capable of existence in presence of an excess of alkaline hydroxide. But if a derivative of a hydrocarbon contain two or more electronegative atoms or groups of atoms in the molecule, then, as a rule, this compound forms metallic derivatives of considerable stability. Thus, the replacement of two atoms of hydrogen in the molecule of an alcohol by an atom of oxygen (converting the group characteristic of primary alcohols, CH_2OH, into the carboxyl group, CO.OH) is attended by a marked increase of acid properties. Similarly the existence of oxygen combined with carbon in hydroxyquinones (as carbonyl, CO) confers on hydroxyl groups present the power of exchanging their hydrogen for metals by reactions common to acids. And in presence of a large amount of an electronegative element the exchangeable hydrogen need not even be present as hydroxyl; for as shown above, such bodies as nitromethane, CH_3NO_2, form metallic derivatives, like CH_2KNO_2. Comp. Aceto-acetic acid, p. 17. Regarding the relations between the nature of different elements and the acidic character of their compounds *v.* further Classification.

Basicity of acids.—Some acids, on treatment with the oxide or hydroxide of an alkali metal, may exchange all their hydrogen for metal, thus producing a salt; and it may not be possible to obtain from them a body intermediate between the salt and the acid; such an intermediate derivative is usually termed an acid salt. From other acids such intermediate derivatives are obtainable. The acids of the former class are termed 'monobasic'; those of the latter class are termed 'polybasic,' including the terms 'di-' 'tri-' 'tetra-' basic. The conception of the basicity of acids was introduced by Graham. Before his researches in 1833, it was supposed that an 'acid salt' contained, as its name implies, both acid and salt, and on the binary theory it was considered to be a compound of the two. But Graham showed that in neutral potassium phosphate there are, as he expressed it, three equivalents of potash for one equivalent of phosphoric acid, or in modern language, three atoms of potassium for one atomic group PO_4; and that the acid phosphates differ from the neutral phosphate in containing water instead of potash, or as we should say, hydrogen in place of potassium. The composition of hydrated phosphoric acid being expressed by the symbol (old notation) $PO_5.3HO$, the composition of its different salts might be expressed by the symbols:

$$PO_5.2HO.KO;\ PO_5.HO.2KO;\ PO_5.3KO.$$

Phosphoric acid was therefore termed by Graham a 'tribasic acid.' In 1838, Liebig pointed out the necessity of considering the following acids as polybasic, because of the fact that they form acid as well as neutral salts;—cyanuric, malonic, comenic, citric, aconitic, aconic, tartaric, malic, and fumaric. In consequence of this change of view, Liebig argued that it was better to give up the binary theory of acids held by Berzelius, and to go back to the older theory of Davy, viz. that acids are to be regarded as formed by the combination of hydrogen with a simple or a compound radicle, the nature of this radicle having no part in determining the number of stages in which the replacement of hydrogen by metal takes place. Thus by addition of oxygen or sulphur to sulphuretted

hydrogen (sulphydric acid) the following dibasic acids are obtainable:—

Sulphydric acid	H_2S
Hyposulphurous acid	H_2SO_2
Sulphurous acid	H_2SO_3
Sulphuric acid	H_2SO_4
Thiosulphuric acid	$H_2S_2O_3$
Dithionic acid	$H_2S_2O_6$

It was, however, known that many acids, having a claim to be considered monobasic, such as hydrofluoric, acetic, benzoic, and stearic, gave rise to double salts by addition of a molecule of acid to a molecule of salt. Laurent and Gerhardt pointed out that the relative densities, in the gaseous state, of many acids belonging to this class imply that a molecule of each acid contains only one atom of hydrogen; further, that an acid of this class forms only one alkyl (or ethereal) salt, and one amide; that while polybasic acids generally yield anhydrides by some direct process, often by the action of heat alone, the anhydrides of monobasic acids are usually obtained indirectly, and that anhydro-salts such as dichromate of potassium, are obtainable only from polybasic acids.

The number of atoms of hydrogen contained in a molecule of an acid is no criterion of its basicity; this fact was noticed by Gerhardt, but its bearings were more fully elucidated by Wurtz and by Kekulé. The basicity of an acid is determined, not by the number of atoms of hydrogen which it contains, but by the number of stages in which the hydrogen can be replaced, or in other words, by the number of salts which it is capable of forming with a specified monovalent metal. Thus a study of the salts of the following acids has led to their classification as shown below.

Monobasic.—HF, HCl, HNO_3, $H(H_2PO_2)$, $H(HCO_2)$, HBF_4, $HAuCl_4$.
Dibasic.—H_2SO_4, $H_2(HPO_3)$, $H_2C_2O_4$, H_2PtCl_6, $C_2H_4(COOH)_2$.
Tribasic.—H_3PO_4, $H_3Fe(CN)_6$, H_3AsO_4, $C_3H_4(OH)(COOH)_3$, $C_3H_2N(COOH)_3$
Tetrabasic.—$H_4P_2O_7$, $H_4Fe(CN)_6$, $C_6H_2(COOH)_4$.
Hexabasic.—$C_6(COOH)_6$.

The number of salts of a monovalent metal which an acid is capable of forming corresponds, as a rule, with its basicity. Thus tribasic orthophosphoric acid forms three salts with potassium, viz. H_2KPO_4, HK_2PO_4, and K_3PO_4; and similarly with other acids.

This classification, as already stated, is founded on a study of the salts of acids containing monovalent metals, practically of the salts formed by the action of potash or soda on the acids. The researches of Thomsen on the quantities of heat produced when acids and bases mutually react in equivalent quantities have confirmed the conclusions drawn from a study of the composition of salts. The principle of the thermal method may be thus stated:—If a dilute aqueous solution of a monobasic acid is mixed with an equivalent quantity of an alkali also in dilute aqueous solution, a definite quantity of heat is produced; if more than one equivalent of acid is used for one equivalent of base, the same quantity of heat is produced. This is shown by the examples which follow:[1]

Acid.	Number of equivalents of acid to one equivalent of base (NaOHAq)		
	2	1	½
HCl.HBr.HI	13,700	13,700	6,850
HF. . .	16,000	16,300	8,200
HSH . .	7,700	7,700	3,900
HNC . .	2,800	2,800	1,400
HNO_3 . .	13,600	13,700	6,800
HPH_2O_2 .	15,400	15,200	7,600
HPO_3 . .	14,200	14,400	—
$H.C_2H_3O_2$.	13,200	13,200	8,600

In most of these instances, the acid forms no acid salt; its hydrogen is replaceable in only one stage. But although acid salts of acetic acid (*e.g.*, $C_2H_4O_2.C_2H_3NaO_2$), and of hydrofluoric acid (HF.KF), are known, the formation of these salts by the action of the neutral salt and the acid is accompanied by a very small thermal change. This fact forms a reason, in addition to those adduced by Gerhardt, for classing hydrofluoric and acetic acids with the monobasic acids.

The thermal value of the action of a base on a polybasic acid, unlike that of the action of a base on a monobasic acid, is dependent on the proportion between the number of equivalents of base and acid used. This is shown by the following examples:

Acid.	Number of equivalents of acid to one equivalent of base (NaOHAq).					
	2	1	½	⅓	¼	⅙
H_2SO_4 .	14,200	14,600	15,500	—	7,800	—
H_2SO_3 .	—	15,900	14,500	—	7,300	—
H_2PHO_3 .	14,900	14,800	14,200	9,600	—	—
H_2CO_3 .	—	11,000	10,100	—	—	—
H_3PO_4 .	14,700	14,800	13,500	11,300	—	5,900
$H_4P_2O_7$.	—	14,400	14,300	—	13,200	9,100

Again, a small thermal change is noticed when solutions of a monobasic acid and of the potassium or sodium salt of this acid mutually react; but if a solution of a polybasic acid is allowed to react with a solution of a neutral salt of the same acid, a marked thermal change occurs. Thus the formation of $KHSO_4$ from K_2SO_4 and H_2SO_4 at 23° is accompanied by the disappearance of about 8,000 gram-units of heat.

ORTHO-ACIDS AND ANHYDRO-ACIDS.—The acids containing oxygen have been most completely investigated, owing to the fact that most of them are stable at ordinary temperatures, and in presence of air and water. It is inferred that in these acids oxygen and hydrogen are in intimate union, forming a hydroxyl group; the chief reason for this view, *viz.*, that when these acids are treated with phosphorous, or phosphoric, chloride they yield the chloride of the acid radicle, has already been stated. Thus sulphuric acid, $SO_2(OH)_2$, yields sulphuryl chloride, SO_2Cl_2; and phosphoric acid, $PO(OH)_3$, yields phosphoryl chloride, $POCl_3$. Such groups as SO_2, sulphuryl, or PO, phosphoryl, are termed acid radicles, and their compounds with hydroxyl are acids. The term ortho-acid is employed especially in the nomenclature of carbon acids.

An ortho-acid, strictly speaking, is one in which the element to which the hydroxyls are

---

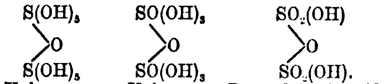
[1] Figures represent gram-units of heat.

united is not combined with any other oxygen. Such compounds are in most cases unknown, but their existence is inferred from that of their metallic or ethereal salts, *e.g.* $Si(ONa)_4$; $C(OCH_3)_4$; $CH_3C(OC_2H_5)_3$, &c.

Many of the commonly occurring acids may be regarded as derived from such ortho-acids by removal of water; thus looked at, these acids are partial anhydrides. Their formation is illustrated by the following examples:

$S(OH)_6$	$SO(OH)_4$	$SO_2(OH)_2$	SO_3	
Unknown.	Unknown.	Sulphuric acid.	Sulphuric anhydride.	
$I(OH)_7$	$IO(OH)_5$	$IO_2(OH)_3$	$IO_3(OH)$	I_2O_7
Unknown.	Periodic acid.	Salts known.	Salts known.	Periodic anhydride (? known)
$P(OH)_5$	$PO(OH)_3$	$PO_2(OH)$	P_2O_5	
Unknown.	Orthophosphoric acid.	Metaphosphoric acid.	Phosphoric anhydride.	

Partial anhydrides are sometimes also formed by the condensation-products of two or more molecules of an acid, with removal of water, thus:



Unknown. Unknown. Pyrosulphuric acid.

In most cases the composition of such acids is inferred from that of their salts; the very numerous natural silicates may be conveniently classified as salts of such condensed acids (*v.* SILICATES).

AFFINITY (or *avidity*) OF ACIDS.—By measuring the thermal changes which occur when one equivalent of an acid, in dilute aqueous solution, reacts on one equivalent of the neutral salt of another acid, also in dilute aqueous solution, it is possible to determine the proportion in which the base divides itself between the two acids. Measurements have been made by Thomsen, and he has named the proportion in which the base combines with either acid, the *relative avidity* of the acid. Thus when hydrochloric acid (36·4 parts) is added to potassium nitrate (101 parts), both in dilute aqueous solution, the thermal changes which occur point to an equal partition of the base between the two acids; *i.e.* half the potassium exists in the solution as chloride, and half as nitrate. On mixing nitric acid (63 parts) with potassium chloride (74·4 parts), the heat-change points to the same equal partition of the base. Hence it is concluded that the relative avidity, or affinity, of hydrochloric and nitric acids for potash is equal, and is expressed by the number 0·5. The relative avidity seems to be independent of the nature of the base within certain limits; it is also modified only to a small extent by the concentration of the reacting liquids, or by small changes of temperature. This conclusion of Thomsen has received thorough confirmation by the researches of Ostwald; and this is the more valuable inasmuch as Ostwald measured the partition of acids between bases by a method depending on the alteration of volume attending the mixture of an acid with the salt of another acid. The following table gives the relative affinities of some acids towards the base soda; the affinity of hydrochloric acid being taken as unity:—

Acid .	HCl	HBr	HI	HF
Avidity	1	0·89	0·79	0·05
Acid .	HCN	$\frac{H_2SO_4}{2}$	$\frac{H_2SeO_4}{2}$	
Avidity	very small	0·49	0·45	
Acid	HNO_3	$\frac{H_3PO_4}{2}$	$\frac{H_2B_2O_4}{2}$	$CCl_3.COOH$
Avidity	1	0·25	very small	0·36
Acid	$(COOH)_2$	$C_4H_6O_6$	$C_2H_4O_2$	
Avidity	0·24	0·05	0·03	

For more details *v.* AFFINITY, p. 67; ACIDS, BASICITY OF, p. 51. Regarding acids *v.* also CLASSIFICATION. An acid with a large avidity or affinity is frequently now spoken of as a *strong acid*, the term *weak* being applied to those acids the affinities of which are expressed by small numbers.

W. R.

ACIDS, BASICITY OF.—It has been shown in the art. ACIDS (*q. v.*) that some acids react with the hydroxide (or oxide) of potassium or sodium to form only one salt, whereas other acids by a similar reaction produce more than a single salt. The former acids are called monobasic, the latter polybasic. It was also shown in the art. ACIDS that the basicity of an acid may be determined by an examination of the *heat of neutralisation* of the acid. The thermal value of the reaction of a monobasic acid with a base, in dilute aqueous solutions, is independent of the ratio between the numbers of equivalents of acid and base used, provided not less than one equivalent of base is mixed with a single equivalent of acid; but the thermal value of the reaction of a polybasic acid with a base varies according as 1, 2, 3, &c. equivalents of base react with one equivalent of acid. If the thermal reactions which occur when acids and bases react in equivalent quantities, and in dilute aqueous solutions, are more closely examined it is found that the dibasic and tribasic acids fall into certain classes. Thomsen has especially examined this subject (*Th.* 1). The quantity of heat produced during the neutralisation of a dibasic acid is sometimes divisible into two exactly equal parts, according as one or two formula-weights of soda are allowed to react with one formula-weight of the acid. In other cases the thermal value of each stage of the total operation is different. Thus consider the following data:

$[H^2SiF^6Aq, NaOHAq] = 13{,}300$ $[H^2SO^4Aq, NaOHAq] = 14{,}750.$

$[H^2SiF^6Aq, 2NaOHAq] = 2 \times 13{,}300$ $[H^2SO^4Aq, 2NaOHAq] = (2 \times 14{,}750) + 1{,}900.$

$[H^2SO^3Aq, NaOHAq] = 15{,}850$

$[H^2SO^3Aq, 2NaOHAq] = (2 \times 15{,}850) - 2{,}750.$

Each of these three acids represents a group.

Thomsen divides the dibasic acids examined by him into three groups according as the thermal value of the action of the second formula-weight of soda is (1) equal to, (2) greater than, or (3) smaller than, the value of the action of the first formula-weight.

The data are presented in the following table:—

GROUP I.

Heat produced in action of NaOH	Acid H_2SiF_6	 H_2PtCl_6
1st formula-weight	13,300	13,600
2nd " "	13,300	13,600

GROUP II.

	H_2SO_4	H_2SeO_4	$H_2C_2O_4$	$H_2C_4H_4O_6$
1st " "	14,750	14,750	13,850	12,450
2nd " "	16,650	15,650	14,450	12,850

GROUP III.

	H_2SO_3	H_2SeO_3	H_2CO_3	$H_2B_2O_4$
1st " "	15,850	14,750	11,000	11,100
2nd " "	13,100	12,250	9,150	8,900

	H_2CrO_4	H_2PHO_3	$C_2H_4(CO_2H)_2$
1st " "	13,150	14,850	12,400
2nd " "	11,550	13,600	11,750

The tribasic acids examined by Thomsen may also be classified according as the thermal value of the action of the second formula-weight of soda is greater or smaller than that of the first, and the value of the action of the third formula-weight is greater or smaller than that of the second. The data are as follows:—

GROUP I.

Heat produced in action of NaOH	Acid $H_3C_6H_3O_6$ (Aconitic Acid)	 $H_3C_6H_5O_7$ (Citric Acid)
1st formula-weight	12,850	12,650
2nd " "	12,950	12,800
3rd " "	13,350	13,550

GROUP II.

Heat produced in action of NaOH	Acid H_3AsO_4	 H_3PO_4
1st formula-weight	15,000	14,850
2nd " "	12,600	12,250
3rd " "	8,350	6,950

Group I. of the tribasic acids corresponds to Group II. of the dibasic, and Group II. of the tribasic, to Group III. of the dibasic, acids.

Thomsen suggests that this classification of dibasic and tribasic acids may be summarised in the following typical formulæ:—

DIBASIC ACIDS.

Acid of Group I.	Typical formula	RH_2	*e.g.* $SiF_6.H_2$;
Acid of Group II.	"	$R(OH)_2$	*e.g.* $SO_2(OH)_2$;
Acid of Group III.	"	$R(OH)H$	*e.g.* $SO_2(OH)H$.

TRIBASIC ACIDS.

Acid of Group I.	Typical formula	$R(OH)_3$	*e.g.* $C_6H_5O_4(OH)_3$;
Acid of Group II.	Typical formula	$HR(OH)H$	*e.g.* $HPO_2(OH)H$.

As regards dibasic acids; in the case of every acid examined by Thomsen, except two, the thermal value of the action of the first quantity of soda added is different from that of the second, equal, quantity of soda. The first of the typical formulæ suggested by Thomsen for the three classes of dibasic acids is probably to be assigned to H_2PtCl_6 and H_2SiF_6 only. Why should the formula $R(OH)_2$ rather than $R(OH)H$ be assigned to the acids of Group II.? The formula $R(OH)H$ would indicate the easy separation of the acids into anhydride (R) and water (OHH). But the acids placed in Group III. are, as a class, more easily separable into anhydride and water than those placed in Group II. If the differences between the thermal values of the first and second quantities of soda acting on the acids of Group III. are tabulated we have this result: $H_2SO_3 = 2{,}750$; $H_2SeO_3 = 2{,}500$; $H_2CO_3 = 1{,}850$; $H_2B_2O_4 = 2{,}200$; $H_2CrO_4 = 1{,}600$; $H_2PHO_3 = 1{,}250$; $C_2H_4(CO_2H)_2 = 650$. These differences vary from 9·5 (H_2SO_3) to 2·7 ($C_2H_4(CO_2H)_2$) per cent. of the total heat of neutralisation. We have good evidence in support of the statement that succinic acid is a dihydroxyl compound; therefore, although it occurs in Thomsen's third group, we must place it with those acids the typical formula of which is $R(OH)_2$, *i.e.* with the acids of Group II. The other acids of Group III. are fairly easily separable into anhydride and water. The formula $CO_2(OH)H$ for carbonic acid is to some extent confirmed by the fact that the higher homologues of this acid although dihydric are distinctly monobasic. If the differences between the thermal values of the first and second quantities of soda acting on the acids of Group II. are tabulated we have this result: $H_2SO_4 = 1{,}900$; $H_2SeO_4 = 900$; $H_2C_2O_4 = 600$; $H_2H_4C_4O_6 = 400$. These differences vary from 6 (H_2SO_4) to 1·5 ($H_2H_4C_4O_6$) per cent. of the total heat of neutralisation. The differences in the case of acids of Group III. are considerably larger than these. When the difference between the thermal values under consideration is small, and, as a rule, the value of the second quantity of soda is greater than that of the first, Thomsen regards the acid as, generally speaking, belonging to the type $R(OH)_2$; when the difference in question is large and the value of the second quantity of soda is, as a rule, smaller than that of the first, the acid is regarded as belonging to the type $R(OH)H$.

These thermal investigations made by Thomsen point to the performance of definite functions by the different hydrogen atoms in the chemically reacting unit, or group of atoms, of many polybasic acids. Although the reacting unit of a tribasic acid contains three atoms of hydrogen all replaceable by metal under similar conditions, nevertheless the energy-change which accompanies any one of these replacements is often different from the energy-change which accompanies the other replacements; hence we seem justified in concluding that each of the replaceable atoms of hydrogen in these acids is related to the rest of the atoms, which with the specified atom make up the chemically reacting unit of the acid, in a way different from that wherein the other replaceable atoms of hydrogen are related to the rest of the atomic complex in question.

In such acids as H_2SO_3, H_3PO_4, &c., it is necessary to exhibit the differences of function of the different replaceable atoms of hydrogen by formulæ which represent some of these acids as containing one OH group, others as containing two OH groups, and others three OH groups; but acids are known the reactions of which

oblige us to say that they contain more than one OH group, and at the same time to assert that each of these groups plays a different part in the reactions of the acid. Thus, glycollic acid $CH_2OH.COOH$ is a monobasic acid; the heat of neutralisation of this acid is

$$[CH^2OH.COOHAq,\ NaOHAq] = 13,600$$

(De Forcrand, *C. R.* 96, 582); but the addition of a second equivalent of soda to the neutral salt is attended with the production of a small quantity of heat

$$[CH^2OH.COONaAq,\ NaOHAq] = 4,200$$

(*ib.*, *Bl.* [2] 40, 104). The disodium glycollate thus formed is, however, an easily decomposed compound. Another monobasic acid, glyoxylic, is known, having the composition $CH(OH)_2.COOH$; this acid forms a definite sodium salt, an aqueous solution of which reacts with soda with the production of nearly one-sixth the quantity of heat produced by the reaction of the first equivalent of soda on the acid. The data are these (De Forcrand, *C. R.* 101, 1495):—

$$[CH(OH)^2.COOHAq,\ NaOHAq] = 13,230;$$
$$[CH(OH)^2.COONaAq,\ NaOHAq] = 2,000.$$

Here we have a very distinct illustration of the connections between thermal changes and the modification in the nature of the reaction of a specified group of atoms produced by the relations of that group to the other atoms, or group of atoms, in the chemically reacting unit of an acid (*v.* further AFFINITY; especially pp. 74, 75).

M. M. P. M.

ACIDS, ORGANIC. The empirical formula of acetic acid $C_2H_4O_2$ has been expanded into the structural formula $CH_3CO.O.H$ by reason of the following considerations. One fourth of the hydrogen of acetic acid is displaceable by metals; hence we write $C_2H_3O_2.H$. By the action of PCl_3, acetic acid may be made to exchange the same quantity of hydrogen together with half its oxygen for chlorine, producing acetyl chloride, C_2H_3OCl: hence we write $C_2H_3O.OH$. In the electrolysis of potassium acetate, ethane and carbonic acid are produced at the positive pole, potassium being formed at the negative pole. This decomposition may be represented thus; $C_2H_3O_2K = K + CO_2 + CH_3$; but methyl, CH_3, is immediately polymerised, becoming ethane, C_2H_6. This experiment shows that half of the carbon in acetic acid is intimately connected with oxygen, the other half being connected especially with hydrogen: hence we write, finally, $CH_3.CO.O.H$.

Analogous reasoning applied to other organic acids, very frequently leads to a similar formula, *e.g.* in the case of succinic acid to the formula $C_2H_4(CO.O.H)_2$. The acid character of these bodies is undoubtedly connected with the group $CO.O.H$ or CO_2H called *carboxyl*, and it is easy to generalise and say that all organic acids that are free from sulphur, phosphorus, arsenic or silicon, contain carboxyl. Kekulé, therefore, considers that the basicity of an organic acid is determined solely by the number of carboxyls it contains. Such a conclusion can, however, only be maintained, by *defining* an organic acid as a substance containing carboxyl. If this definition be accepted, it follows of course that all organic acids do contain carboxyl. But if we wish to let experiment guide us, we must adopt some other definition, such as that an acid is a substance that contains hydrogen which can be displaced by metals with the formation of a metallic compound not decomposable by water. According to this definition, phenol, pyrogallic acid, nitro-ethane, and even the propargyl derivatives and perhaps acetylene, are acids. Compounds like sugar-lime are not necessarily salts, for the calcium need not have displaced any hydrogen in the sugar, but may have added itself in some way.

Sodic carbonate gives off CO_2 when mixed with solutions of strong acids; if we adopt effervescence with sodic carbonate as a test of acidity, we shall consider the compounds just mentioned to be neutral bodies, but the nitrophenols and barbituric acid will still be acids. In testing with sodic carbonate we assume that carbonic acid is the weakest of all acids; this is a mere convention, the fact being that there is no definite line of demarcation between acids and neutral bodies, the two series shading off imperceptibly into one another.

It will be noticed that the acidity of phenol is greatly increased by the introduction of nitroxyl. In general, the displaceable hydrogen in an acid must be directly and indirectly attached to strong chlorous (or electro-negative) elements or radicles, for it is the balance of affinities between these elements or radicles and the metal that produces the stability of the salt. In carboxylic salts one O directly, and CO indirectly, neutralise or balance the metal, say sodium, forming the stable group CO.O.Na.

In sodium nitro-phenol, $NO_2.C_6H_4.O.Na$, the sodium is balanced by O directly and by NO_2 indirectly. In sodium nitrate, $NO_2.O.Na$, the condition of the molecule is similar (*v.* also ACETO-ACETIC ACID, p. 22). Too many or too few chlorous groups weaken an acid, for the equilibrium of its salts is thereby destroyed. Thus aldehyde, $CH_3.CO.H$ is a neutral body, while hydric hypochlorite, Cl.O.H, is a weaker acid than Cl.H.

For purposes of classification, it is most convenient to arrange acids according to their structural formulæ. Compounds whose structural formulæ exhibit closed rings, each containing more than two atoms, are classed as *aromatic*, a term that is more particularly applied to the derivatives of benzene; all other organic compounds belong to the *fatty* series.

Carboxylic acids of each series may be arranged according to their formulæ and general characters as follows:

A. *Fatty Series.*

(*a.*) *Monocarboxylic acids*: α. Mono-hydric: Series I, $C_nH_{2n}O_2$ or Acetic Series; Series II, $C_nH_{2n-2}O_2$ or Acrylic Series; Series III, $C_nH_{2n-4}O_2$ or Propiolic Series; Series IV, $C_nH_{2n-6}O_2$, *e.g.* tri-ethenyl-butyric.—β. Di-hydric: Series I, $C_nH_{2n}O_3$ or Lactic Series; Series II, $C_nH_{2n-2}O_3$, *e.g.* Oxy-acrylic; Series III, $C_nH_{2n-4}O_3$, *e.g.* oxypentinoic.—γ. Tri-Hydric: $C_nH_{2n}O_4$ or Glyceric Series.—δ. Ketonic: Series I, $C_nH_{2n-2}O_3$, *e.g.* aceto-acetic acid; Series II, $C_nH_{2n-4}O_3$, *e.g.* allyl-aceto-acetic acid; Series III, $C_nH_{2n-6}O_3$, *e.g.* di-allyl-aceto-acetic acid.—ε. Di-ketonic: $C_nH_{2n-4}O_4$, *e.g.* acetyl-aceto-acetic acid.

(*b.*) *Di-carboxylic acids*: α. Di-hydric: Series I, $C_nH_{2n-2}O_4$ or Oxalic Series;

Series II, $C_nH_{2n-4}O_4$, *e.g.* fumaric acid; Series III, $C_nH_{2n-6}O_4$, *e.g.* acetylene di-carboxylic acid; Series IV, $C_nH_{2n-10}O_4$, *e.g.* di-acetylene di-carboxylic acid.—β. Tri-hydric: Series I, $C_nH_{2n-2}O_5$, malic series; Series II, $C_nH_{2n-4}O_5$, *e.g.* oxy-itaconic acid. — γ. Tetra-hydric, $C_nH_{2n-2}O_6$, *e.g.* tartaric acid.—δ. Penta-hydric, $C_nH_{2n-2}O_7$, *e.g.* tri-oxy-adipic acid.—ε. Hexa-hydric, $C_nH_{2n-2}O_8$, *e.g.* saccharic acid.—ζ. Ketonic, $C_nH_{2n-4}O_5$, *e.g.* acetyl-succinic acid.—η. Di-ketonic, $C_nH_{2n-6}O_6$, *e.g.* di-acetyl-succinic acid.

(*c*) *Tri-carboxylic acids*: α. Tri-hydric: Series I, $C_nH_{2n-4}O_6$, *e.g.* tricarballylic acid; Series II, $C_nH_{2n-6}O_6$, *e.g.* aconitic acid.—β. Tetra-hydric: $C_nH_{2n-4}O_7$, *e.g.* citric acid.—γ. Penta-hydric: $C_nH_{2n-4}O_8$, *e.g.* desoxalic acid.—δ. Ketonic: $C_nH_{2n-6}O_7$, *e.g.* acetyl-tricarballylic acid.

(*d*) *Tetra-carboxylic acids*: α. Tetra-hydric $C_nH_{2-6}O_8$, *e.g.* ethane tetra-carboxylic acid.

B. *Aromatic Series.* It is obvious that when rings of atoms are introduced into the structural formulæ, the empirical formulæ become very complicated. We shall therefore not attempt fully to classify the aromatic acids. The most important series are as follows:

(*a.*) *Mono-carboxylic acids*, α. Mono-hydric: $C_nH_{2n-8}O_2$, *e.g.* benzoic acid; $C_nH_{2n-10}O_2$, *e.g.* cinnamic acid; $C_nH_{2n-12}O_2$, *e.g.* phenyl-propiolic acid; $C_nH_{2n-14}O_2$, *e.g.* naphthoic acid; $C_nH_{2n-16}O_2$, *e.g.* di-phenic acid; $C_nH_{2n-18}O_2$, *e.g.* phenyl-cinnamic acid; $C_nH_{2n-20}O_2$, *e.g.* anthracene carboxylic acid; $C_nH_{2n-24}O_2$, *e.g.* tri-phenyl-acetic acid.—β. Di-hydric: $C_nH_{2n-8}O_3$, *e.g.* salicylic acid; $C_nH_{2n-10}O_3$, *e.g.* coumaric acid.—γ. Tri-hydric: $C_nH_{2n-8}O_4$, *e.g.* protocatechuic acid, $C_nH_{2n-10}O_4$, *e.g.* oxy-coumaric acid.—δ. Tetra-hydric, $C_nH_{2n-8}O_5$, *e.g.* gallic acid.—ε. Ketonic: $C_nH_{2n-10}O_4$, *e.g.* oxy-acetophenone carboxylic acid.

(*b.*) *Di-carboxylic acids*: α. Di-hydric: $C_nH_{2n-8}O_4$, *e.g.* hydro-terephthalic acid; $C_nH_{2n-10}O_4$, *e.g.* phthalic acid.—β. tri-hydric: $C_nH_{2n-10}O_5$, *e.g.* oxy-phthalic acid.

The more complicated aromatic acids may be classified in a similar way. It will be seen that they are all poorer in hydrogen than the corresponding fatty acids.

Organic Acids in general.—*Occurrence*: In the vegetable kingdom, *e.g.* oxalic, malic, tartaric, benzoic, salicylic, cinnamic, veratric, gallic, and tannic acids. In animal juices and secretions, *e.g.* lactic, sarcolactic, uric, hippuric, glycocholic, and taurocholic acids. In decaying organised matter, *e.g.* acetic, butyric, valeric, amido-propionic, amido-hexoic, and glutamic acids.

Formation.—1. By decomposing products of the animal or vegetable kingdom by boiling with dilute acids, *e.g.* amido-acetic, aspartic and glutamic acids.—2. From fats and fatty oils by boiling with alkalis, *e.g.* stearic, palmitic, and oleic acids.—3. From resins by potash-fusion, *e.g.* *p*-oxy-benzoic and protocatechuic acids.—4. By boiling a variety of substances with dilute nitric acid (S.G. 1·2), *e.g.* oxalic and tartaric acids from sugar and other carbohydrates.—5. By oxidising aromatic hydrocarbons and other bodies with chromic mixture (2 pts. of $K_2Cr_2O_7$, 3 pts. of H_2SO_4 and 3 to 5 parts of water), *e.g.* benzoic and terephthalic acids.—6. By oxidation with $KMnO_4$, *e.g.* vanillic acid from coniferin, pyridine carboxylic acids from methyl-pyridines.—7. From nitriles by boiling with KOH, *e.g.* acetic and succinic acids. Unstable nitriles must be first converted into amides by cold conc. HCl, and the amides may then be turned into acids by boiling dilute HCl, *e.g.* pyruvic acid (Claisen). The nitriles may be prepared from alkyl chlorides or potassic alkyl sulphates by distilling with KCy or digesting with $HgCy_2$. No nitriles of the form $XYC(CN)_2$ are known (Claus), hence derivatives of malonic acid cannot be prepared in this way.—8. By the oxidation of primary alcohols: $X.CH_2.OH + O_2 = X.CO.OH + H_2O$. Secondary and tertiary alcohols can only produce acids with a less number of carbon atoms, *e.g.* $CH_3.CH(OH).CH_3 + 5O = CH_3CO_2H + CO_3H_2 + H_2O$.

Preparation.—The acids may be separated from insoluble neutral and alkaline substances by solution in aqueous potash; they may then be liberated by H_2SO_4 and purified by one of the following methods:

(*a.*) If they are volatile, they are distilled alone or with steam.

(*b.*) By conversion into a lead, barium, or silver salt and, if possible, purifying the salt by crystallisation. The lead salt is then decomposed by H_2S, the barium salt by the calculated quantity of H_2SO_4, and the silver salt either by H_2S or by the calculated quantity of HCl.

(*c.*) By acidifying and extracting with ether. A large number of acids are soluble in ether.

Reactions.—1. Organic acids may be converted into ethers in two principal ways: (*a.*) By distilling with an alcohol and dilute H_2SO_4. The reaction may be supposed to take place in two stages; the preparation of acetic ether may be thus represented:

$$EtOH + H_2SO_4 = EtHSO_4 + H_2O$$
$$EtHSO_4 + HOAc = EtOAc + H_2SO_4.$$

(*b.*) If an acid is non-volatile, it is dissolved in the alcohol and the liquid is saturated with HCl. After some hours the solution is poured into water and the ppd. ether distilled, if possible, *in vacuo*; the reactions may be thus represented:

$$EtOH + HCl = EtCl + H_2O$$
$$EtCl + HOAc = EtOAc + HCl.$$

It is not necessary that HCl or H_2SO_4 should be present in order that etherification may take place, for if equivalent quantities of an acid and an alcohol be left in contact or heated together for a sufficiently long time, from 64 to 74 p.c. will react upon each other, forming an ether. The rate at which the reaction takes place is greatest for acids of the formula $X.CH_2.CO_2H$, slower for so-called secondary acids, $XYCH.CO_2H$, and slowest for tertiary acids of the type $XYZ.C.CO_2H$, where X, Y and Z are alkyls (Menschutkin, *v.* CHEMICAL CHANGE).—2. Chlorides of phosphorus convert acids or their salts into acid chlorides of the form X.CO.Cl. These are usually soluble in ether, and are decomposed by water, more or less rapidly, into HCl and the acid X.CO.OH. Oxy-acids exchange not only their carboxylic hydroxyl for Cl, but also their other hydroxyls; but the chlorides so produced are not reconverted by water into the original acid but only into chloro-acids; thus lactic acid, $CH_3.CH(OH).CO_2H$, is converted by PCl_5 into lactyl chloride, $CH_3.CHCl.COCl$, whence water reproduces chloropropionic acid, $CH_3.CHCl.CO_2H$. The chlorides act upon dry nitrates of the heavy metals (Ag, Pb, Cu, Zn, and Hg) producing anhydrides, *e.g.*:

$$2Ph.CO.Cl + Pb(NO_3)_2 = (Ph.CO)_2O + PbCl_2 + N_2O_4 + O$$

(Lachowicz, *B.* 18, 2990).—3. Amides are formed by the action of NH_3 either upon the chlorides: $X.COCl + 2NH_3 = X.CO.NH_2 + NH_4Cl$, or ethers: $X.CO.OEt + NH_3 = X.CO.NH_2 + HOEt$. The amides are usually crystalline substances, and their melting-points form important means of recognising the various acids.—4. Acetyl chloride converts acids into anhydrides (*v.* ACETYL CHLORIDE).—5. $COCl_2$ converts salts into anhydrides.—6. By heating with CaO or BaO, or sometimes by heating alone, CO_2 can be eliminated from the carboxyls.—7. Dry distillation of calcium or barium salts usually produces ketones (*q. v.*).—8. Distillation of calcium salts with calcium formate usually produces aldehydes (*q. v.*).

Salts.—Salts are formed by neutralising the acids with metallic oxides or carbonates. They can be conveniently obtained by the addition of metallic sulphates or soluble carbonates to a solution of the barium salt of the acid, or of soluble chlorides to the solution of the silver salt. Sodium, added to ethereal or alcoholic solutions of oxy-acids, displaces not only carboxylic but also hydroxylic hydrogen. The compounds so produced are, in many cases, partly decomposed by water, the sodium that has displaced alcoholic hydroxyl being turned out again, *e.g.* $CH_3.CH(ONa).CO_2Na + H_2O = CH_3.CH(OH).CO_2Na + NaOH$. The silver salt is usually the least soluble, and is frequently used in determining the molecular weight of an acid; for when the basicity of an acid is known the molecular weight can be deduced from the percentage of silver left after strongly heating the salt. Silver salts seldom contain water of crystallisation.

Acetic Series $C_nH_{2n}O_2$. *Nomenclature.*—The following names are employed in this dictionary, the numbers denoting the value of n: 1. formic acid, 2. acetic acid, 3. propionic acid, 4. butyric acid, 5. valeric acid, 6. hexoic acid = caproic acid, 7. heptoic acid = œnanthic acid, 8. octoic acid = caprilic acid, 9. ennoic acid = nonylic acid = pelargonic acid, 10. decoic acid = capric acid, 11. hendecoic acid = undecylic acid, 12. dodecoic acid = lauric acid, 13. tridecoic acid, 14. tetradecoic = myristic acid, 15. pentadecoic acid, 16. palmitic acid = hexadecoic acid, 17. heptadecoic acid, 18. stearic acid = octodecoic, 19. enendecoic acid = arachic acid, 20. behenic acid = icosoic acid.

Formation.—Besides the general methods described above, the following may be noticed:—1. The action of CO_2 upon sodium alkyls, *e.g.* $NaC_2H_5 + CO_2 = C_2H_5.CO_2Na$. This gives one method for preparing fatty acids from compounds containing a fewer number of atoms of carbon in the molecule; another method depends upon the saponification of alkyl cyanides (*v. supra*).—2. The action of strong KOH upon alkylated aceto-acetic ethers (*q. v.*).—3. The distillation of alkyl-malonic acids: $XYC(CO_2H)_2 = XYCH.CO_2H + CO_2$, where X and Y may be alkyls or hydrogen. Other di-basic acids are decomposed in a similar way when their solutions are mixed with uranium nitrate solution and exposed to sunlight.—5. By heating sodium alcoholates with CO gas: $NaOEt + CO = EtCO_2Na$.—6. By reducing oxy-acids by heating with HI.—7. By reducing unsaturated acids by HI or sodium-amalgam.

Reactions.—1. Dry distillation of salts of the alkaline earths or alkalis produces ketones: *e.g.*

$$Ca(O.CO.Me)_2 = CaCO_3 + COMe_2.$$

2. Distillation of a mixture of such salts of two acids produces mixed ketones:

$$KO.CO.Me + KO.CO.Et = K_2CO_3 + Me.CO.Et.$$

If one of the salts be a formate the product is an aldehyde:

$$KO.CO.Me + KO.CO.H = K_2CO_3 + Me.CO.H.$$

3. Distillation of a salt of a fatty acid with an alkaline hydrate produces a hydrocarbon:

$$KO.CO.Me + KO.H = K_2CO_3 + MeH.$$

4. Distillation of the alkaline saltsw ith As_2O_3 gives organic compounds containing ARSENIC (*q.v.*)
5. Electrolysis gives saturated hydrocarbons:

$$2C_nH_{2n+1}.CO_2K = K_2 + 2CO_2 + C_{2n}H_{4n+2}.$$

6. Chlorine and bromine act by substitution, not by addition.—7. Distillation in a current of steam of the mixture of stearic, palmitic, and oleic acids got from fat slightly decomposes them, forming all acids of the series from formic to octoic (Cahours a. Demarçay, *C. R.* 90, 156).

Synthesis.—The acids of the acetic series may be built up in the following way:—(*a*) NaMe is converted into $NaCO_2Me$, or sodic acetate, by CO_2 (Wanklyn).—(*b*) Sodic acetate is converted into ethyl alcohol in one of three ways: **α**. It is converted by $POCl_3$ into Ac_2O, and this is reduced by sodium-amalgam (Linnemann).—**β**. Ammonic acetate is prepared, and is converted by P_2O_5 into acetonitrile: $NH_4CO_2Me = 2H_2O + NCMe$; the nitrile is then reduced by Zn and H_2SO_4 (Mendius) to an amine: $NCMe + 2H_2 = H_2N.CH_2Me$, which is converted by nitrous acid into an alcohol: $H_2N.CH_2Me + HNO_2 = HO.CH_2Me + N_2 + H_2O$. This last reaction is, however, accompanied by an intra-molecular change in the case of all the amines except ethylamine and methylamine; as a result of this change *n*-propylamine gives rise to secondary as well as *n*-propyl alcohol.—γ. The sodic acetate is mixed with sodic formate and distilled; the aldehyde thus got is reduced to alcohol by sodium-amalgam (Lieben a. Rossi), or the oxim of the aldehyde is reduced to an amine which is then treated with nitrous acid.—(*c*) Ethyl alcohol so prepared can now be turned into ethyl iodide, zinc ethide, and sodium ethide, successively.

A repetition of processes (*a*), (*b*) and (*c*) upon NaEt will produce sodic propionate, propyl alcohol, and sodic propide successively, and so we can build up the series of fatty acids.

Instead of using the sodium alkyls, it is more convenient to use alkyl cyanides; the process is then: (*a*) convert methyl alcohol into methyl cyanide, and this, by saponification, into acetic acid; (*b*) convert acetic acid into ethyl alcohol by one of the three processes, α, β, or γ, just mentioned; (*c*) convert ethyl alcohol into ethyl cyanide, and proceed as before to prepare propionic acid, propyl alcohol &c. The acids of the acetic series may also be prepared synthetically with the aid of aceto-acetic ether (p. 22) or of malonic ether (*q. v.*). In this way any acid of the form $CHXY.CO_2H$, where X and Y are alkyls, can be prepared.

The descent of the acetic series may be effected by distilling each acid with soda-lime, whereby a hydrocarbon containing one atom of carbon less is got; this hydrocarbon is converted by chlorine into an alkyl chloride, whence by successive treatment with AgOAc and KOH an alcohol may be formed.

The descent may also be effected by converting the acid into an amide, mixing this with bromine and pouring the mixture into a 10 per cent. solution of NaOH. An amine, a nitrile, and a derivative of urea are then formed, the amine and the nitrile contain one atom of carbon less than the amide. The amine may be turned into an alcohol by nitrous acid, and then oxidised to an acid; while the nitrile gives the acid on mere saponification. The amides containing at least 8 carbon atoms yield large quantities of nitrile, while the lower amides produce chiefly amine (Hofmann, *B.* 17, 1408). The descent through nitrile from ennoic to octoic acid may be thus represented:

$$C_8H_{17}CONH_2 + 3Br_2 + 8NaOH =$$
$$C_7H_{15}CN + 6NaBr + Na_2CO_3 + 6H_2O.$$
$$C_7H_{15}CN + KOH + H_2O = C_7H_{15}CO_2K + NH_3.$$

Melting Points.—While the boiling points of the acetic series of acids gradually rise with each increment of CH_2, the melting-points of those acids that contain an odd number of atoms of carbon appear to be lower than those of the acids that contain one atom of carbon less:

caprilic	[16·5°]	pelargonic	[12·5°]
capric	[30°]	hendecoic	[28·5°]
lauric	[43°]	tridecoic	[40·5°]
myristic	[53·8°]	pentadecoic	[51°]
palmitic	[62°]	margaric	[59·9°]
stearic	[69°]	enendecoic	[59·9°]
arachic	[75°]	medullic (?)	[72·5°]

Isomerism among the fatty acids will be discussed under CLASSIFICATION (*v.* also ISOMERISM).

Separation of two volatile acids.—Divide the acid into two equal parts, neutralise one with potash, add the other and distil. The most volatile acid will pass over in preference to the other; and if it constitutes more than half the entire mixture, the distillate will consist solely of this acid. If, however, the less volatile acid be in excess, the residue will consist of its potassium salt in a pure state. The operation is repeated upon whichever portion is still a mixture. Acetic acid is an exception to the rule, for although it be the more volatile acid, it will remain behind as acid potassium acetate (Liebig, *A.* 71, 355). If the distillation be performed in aqueous solution in a current of steam, the acid of highest molecular weight goes over first (Hecht, *A.* 209, 319).

Separation of fixed acids.—An alcoholic solution of the mixture of acids is fractionally precipitated by a conc. aqueous solution of magnesium or barium acetate or by an alcoholic solution of lead acetate. In the series of pps. so got, the first contains the acid of highest molecular weight and the last the acid of lowest molecular weight. Each fraction is decomposed by boiling dilute HCl and the melting-point taken. If a series of consecutive fractions contains acids of identical melting-point that acid may be considered pure, otherwise the process must be repeated upon each fraction (Heintz, *J. pr.* 66, 1; *A.* 92, 295).

Acrylic Series $C_nH_{2n-2}O_2$. *Nomenclature.*—n = 3, acrylic; 4, crotonic; 5, angelic; 6, hexenoic; 7, heptenoic; 8, octenoic = suberonic; 9, ennenoic; 10, decenoic = campholic; 11, hendecenoic = undecylenic; 12, dodecenoic; 14, tetradecenoic; 15, pentadecenoic = cimicic; 16, hexadecenoic = hypogæic; 18, oleic = octodecenoic; 19, doeglic = enendecenoic; 22, erucic and brassic acids.

Occurrence.—As compound ethers in fats and oils, *e.g.* oleic acid.

Formation.—1. From β-, and sometimes from α-, bromo- or iodo- derivatives of the acetic series by boiling with alkalis or Ag_2O:

$$CH_2I.CH_2.CO_2K + KOH =$$
$$CH_2{:}CH.CO_2K + KI + H_2O.$$

2. From β-oxy-acids, by distillation:

$$CH_2OH.CH_2.CO_2H = H_2O + CH_2{:}CH.CO_2H.$$

3. From certain β-oxy-ethers by PCl_3:

$$3CMe_2OH.CO_2Et + 2PCl_3 =$$
$$3CMe_2Cl.CO_2Et + P_2O_3 + 3HCl$$
$$CMe_2Cl.CO_2Et = CH_2{:}CMe.CO_2Et + HCl$$

(Frankland a. Duppa, *C. J.* [2] 3, 133). Similarly $Me_2C(OH).CH_2.CO_2Et$ gives $Me_2C{:}CH.CO_2Et$.—4. From derivatives of aceto-acetic or malonic ethers containing allyl, ethylene, &c.—5. By Perkin's reaction, by heating aldehydes, $C_nH_{2n}O$, with sodic acetate and Ac_2O (*v.* ALDEHYDES).

Properties.—As in the acetic series, the lower members of the acrylic series are volatile liquids miscible with water. Solubility and specific gravity diminish as molecular weight and boiling point increase. The higher members are non-volatile and insoluble in water.

Reactions.—1. The acids of this series contain the group C:C and consequently combine directly with bromine and chlorine, usually with HBr or HI in conc. solution, and frequently with H_2, the latter combination is effected either by action of sodium amalgam on a solution in water or alcohol or by heating with conc. HI.—2. Fusion with potash produces two acids, one of which is almost always acetic acid. The molecular formula is split up in the middle of the group C:C, *e.g.*:

$$CH_3.CH{:}CH.CO_2H + 2KOH =$$
$$CH_3CO_2K + H_2CH.CO_2K + H_2.$$

3. Boiled dilute with H_2SO_4, they often change into the lactone of saturated oxy-acids: thus hydro-sorbic acid, $CH_3.CH{:}CH.CH_2.CH_2.CO_2H$, changes into oxy-hexo-lactone,

$$CH_3.CH_2.\underbrace{CH.CH_2.CH_2.CO.O}_{}$$

4. Many of the higher members are polymerised by nitrous acid.

Series $C_nH_{2n-4}O_2$. *Nomenclature.*—n = 3. Propiolic; 4, tetrolic; 5, pentinoic; 6, hexinoic = sorbic; 7, heptinoic = benzoleic; 8, octinoic = di-allyl-acetic; 9, lauronolic = enninoic; 10, camphic = decinoic; 11, hendecinoic = undecolic; 14, myristolic = tetradecinoic; 15, pentadecinoic; 16, palmitolic = hexadecinoic; 17, elæomargaric = heptadecinoic; 18, stearolic = octodecinoic; 22, behenolic.

Formation.—From di-brominated (or di-chlorinated) acids of the acetic series, or mono-

brominated acids of the acrylic series by treatment with alcoholic KOH.

Reactions.—Combine with Br_2 or with Br_4, also with HBr or 2HBr, and with H_2 and sometimes with H_4.

Lactic Series $C_nH_{2n}O_3$. *Nomenclature.*—n = 2, Glycollic; 3, lactic and hydracrylic; 4, oxybutyric; 5, oxy-valeric; 6, oxy-hexoic &c.—*oxy* being prefixed to the names used in the acetic series.

Formation.—1. By the general methods: thus (7) by saponification of oxy-nitriles, (8) by oxidation of glycols.—2. From bromo-, chloro- or iodo- derivatives of the acetic series by displacing the halogen by hydroxyl: (*a*) by boiling with much water, (*b*) by moist Ag_2O, or (*c*) by KOHAq.—3. From amido-acids by nitrous acid. 4. From aldehydes or ketones by addition of HCN followed by saponification of the resulting cyanhydrin by HCl:

$$CH_3.CHO + HCN = CH_3.CH(OH).CN$$
$$CH_3.CH(OH).CN + HCl + 2H_2O = CH_3.CH(OH).CO_2H + NH_4Cl.$$

5. By oxidation of acids containing methenyl:

$$(CH_3)_2CH.CO_2H + O = (CH_3)_2C(OH).CO_2H.$$

6. By action of zinc alkyls on oxalic ethers:

$$CO_2Et.CO_2Et + 2ZnEt_2 = CO_2Et.CEt_2.OZnEt + EtZnOEt,$$
$$CO_2Et.CEt_2.OZnEt + 2H_2O = CO_2Et.CEt_2.OH + Zn(OH)_2 + C_2H_6.$$

7. By reduction of ketonic acids.

Reactions.—The action of PCl_5 and of Na, and the characters of the resulting compounds have been discussed above. The oxy-acids act as half alcohol and half acid. Thus they form two kinds of monoethylic ethers, one of the form $R''(OH).CO_2Et$, the other of the form $R''(OEt).CO_2H$. The ethers $R''(OH).CO_2Et$ possess all the characters of an ethyl salt of an acid. Thus they may be prepared in the usual way from the acid, alcohol, and HCl; they may be saponified easily by alkalis; they are converted by ammonia into amides $R''(OH).CONH_2$; they are neutral to litmus. The ethers of the form $R''(OEt).CO_2H$ can be prepared by saponifying the diethylic ethers $R''(OEt).CO_2Et$ and these are got from $R''Cl.CO_2Et$ by action of NaOEt. The ethers $R''(OEt).CO_2H$ cannot be saponified by alkalis; are only converted into ammonium salts, $R''(OEt).CO_2NH_4$, by ammonia; and are acid to litmus.

α-oxy-acids are split up by boiling conc. HCl into formic acid and aldehydes:

$$CH_3.CH(OH).CO_2H = CH_3.CHO + HCO_2H.$$

β-oxy-acids boiled with conc. HCl give H_2O and an acid of the acrylic series:

$$CH_2OH.CH_2.CO_2H = CH_2{:}CH.CO_2H + H_2O.$$

γ-oxy-acids split up, when their solution is warmed, into water and lactones (*q. v.*).

$$CH_3.CH(OH).CH_2.CH_2.CO_2H = CH_3.\underbrace{CH.CH_2.CH_2CO.O}_{} + H_2O$$

On dry distillation, the *α*-oxy-acids of the form $R'.CH(OH).CO_2H$ produce lactides, or compound ethers of the form $R'.CH\genfrac{<}{>}{0pt}{}{O.CO}{CO.O}CH.R'$. The *β*-oxy-acids are converted by dry distillation into unsaturated acids:

$$R'.CH(OH).CH_2.CO_2H = R'.CH{:}CH.CO_2H + H_2O,$$

or into an aldehyde and an acid:

$$CH_3.CH(OH).CRR'.CO_2H = CH_3.CHO + HCRR'.CO_2H.$$

Ketonic acids. Carboxylic acids represented by formulæ in which carbonyl is united to two atoms of carbon. The preparation and properties of the ketonic acids got by displacing one or two atoms of hydrogen in aceto-acetic acid by hydrocarbon radicles are described under ACETO-ACETIC ACID. Homologues of aceto-acetic acid in which carbonyl and carboxyl are not both united to the same atom of carbon are described as alkoyl-derivatives of fatty acids; thus, $CH_3.CH_2.CO.CH_2.CH_2.CO_2H$ is described as PROPIONYL-PROPIONIC ACID.

Ketonic acids containing two carboxyls are described as derivatives of di-basic acids, thus $CH_3.CO.CH(CO_2H).CH_2.CO_2H$ is described as acetyl-succinic acid.

Ketonic acids of the form $R'CO.CO_2H$ can be prepared from cyanides of the form $R'.CO.CN$, and also, in the aromatic series, by the action of $HgPh_2$ &c., on $ClCO.CO_2Et$.

Di-basic acids, $C_nH_{2n-2}O_4$.

Formation.—1. By oxidation of the corresponding glycols.—2. By boiling the cyanides of alkylenes with potash. Alkylidene cyanides do not exist (Claus).—3. By saponification of cyano-acids, $C_nH_{2n-1}CyO_2$.—4. By reduction of unsaturated di-basic acids.—5. By action of reduced silver upon iodo-acids (*e.g.* formation of adipic from iodo-propionic acid).—6. By oxidation of fats, fatty acids, ketonic acids, unsaturated acids and many other bodies.—7. By reducing polyhydric di-carboxylic acids by HI, *e.g.* tartaric acid to succinic.—8. From aceto-acetic ethers by acting with NaOEt and the ethyl salt of a chloro- or bromo-acid, and saponifying the product with conc. KOH (*v.* ACETYL-SUCCINIC ETHER).—9. From sodio-malonic ether and alkyl iodides:

$$CHNa.(CO_2Et)_2 + IR = CHR(CO_2Et)_2 + NaI.$$

The product still contains hydrogen displaceable by sodium: $CHR(CO_2Et)_2 + Na = CNaR(CO_2Et)_2 + H$ whence alkyl iodides form di-alkylated malonic ether:

$$CNaR(CO_2Et)_2 + R'I = CR'R(CO_2Et)_2 + NaI$$

(*v.* MALONIC ACID).

Properties.—Solid and not volatile. Frequently produce anhydrides when heated. Malonic acid and its derivatives are split up by heat into CO_2 and acids of the acetic series. In the oxalic series the acids containing an even number of carbon atoms in the molecule have higher melting-points, and lower solubility in water than the acids with an uneven number of carbon atoms (Baeyer, *B.* 10, 1286; Henry, *C.R.* 99, 1157; 100, 60).

For the characters of the homologues of benzoic and salicylic acids see AROMATIC SERIES. See also AMIDO-, BROMO-, CHLORO-, IODO- and NITRO-ACIDS, and SULPHONIC ACIDS.

ACONIC ACID

$$C_5H_4O_4 \text{ i.e. } CO_2H.CH_2.C\genfrac{<}{>}{0pt}{}{CO}{CH}O$$

M. w. 128. [163°-164°]. S. 17·8 at 15°. Formed by boiling itadibromopyrotartaric acid with a caustic alkali, $C_5H_6Br_2O_4 = 2HBr + C_5H_4O_4$ (Kekulé, *A. Suppl.* 1, 338), or with water (10 pts.) (Beer, *A.* 216, 92). In like manner from bromoitaconic acid, $C_5H_5BrO_4$ (Swarts, *J.* 1873, 584). To prepare it, a solution of itadibromopyrotartaric acid neutral-

ised with soda is heated to the boiling point, then gradually mixed with more soda till it contains 3 mol. NaOH to 1 mol. of the acid. On evaporating the solution, sodium aconate crystallises out and aconic acid may be obtained from it by decomposition with sulphuric acid and agitation with ether (Meilly, *A.* 171, 158).

Separates from water in rhombic crystals; from ether in elongated laminæ (M.).

Reactions.—1. Decomposed slowly by boiling water, forming a brown syrup.—2. Does not combine with bromine.—3. Unites with HCl and HBr forming chloro- and bromo-itaconic acids (Swarts).—4. Reduced by Sn or Zn to itaconic acid.—5. Boiling baryta produces formic, succinic and oxy-itaconic acids:

$$C_5H_4O_4 + 2H_2O = CH_2O_2 + C_4H_6O_4 \text{ and}$$
$$C_5H_4O_4 + H_2O = C_5H_6O_5.$$

Salts.—BaA$'_2$: v. sol. water, ppd. by alcohol; crystallises from hot alcohol in shining prisms; gives off 2½ aq. at 150°.—CuA$'_2$4aq: blue prisms.—AgA': sparingly soluble laminæ. NaA'3aq: efflorescent triclinic crystals: $a : b : c$ = ·538 : 1 : ·699; $\alpha = 103°6'$, $\beta = 104°\ 27'$, γ = 84° 49'. Got by boiling ita-di-bromo-pyrotartaric acid with the calculated quantity of aqueous Na_2CO_3. It is decomposed by long boiling with water (B.).—ZnA$'_2$8aq: large shining crystals, melting below 100° in their water of crystallisation.

Methyl Ether. MeA' [85°]. From AgA' and MeI. Long thin prisms, v. sol. ether, m. sol. alcohol, sl. sol. water. H. W.

ACONITANILIC ACID *v.* ANILINE.

ACONITE ALKALOIDS.—1. **Aconitine.** $C_{33}H_{43}NO_{12}$.[183° cor.]. S. ·13; S (benzene or chloroform) 18; S. (ether) 1·56; S. (alcohol) 2·7; S. (petroleum) ·036 (Jürgens, *Ar. Ph.* [3] 24, 127).

Occurrence.—In the root of monk's-hood, *Aconitum Napellus* (Geiger a. Hesse, *A.* 7, 276; Planta, *A.* 74, 257).

Preparation.—The ground root is exhausted with alcohol containing tartaric acid; the concentrated extract, after exposure to the air in shallow dishes to remove the last traces of alcohol, is mixed with water; the aqueous solution is filtered to separate resin, the last portions of which are removed by agitation with light petroleum, and then precipitated with potassium carbonate; the precipitate, consisting chiefly of aconitine, is dissolved in ether, which leaves behind a small quantity of humous substance; the solution is mixed with aqueous tartaric acid and precipitated with sodium carbonate; the precipitate is dissolved in ether; and the etheric solution left to evaporate. The residue consists of nearly pure aconitine, which may be further purified by converting it into hydrobromide, decomposing this salt, after recrystallisation, with sodium carbonate, and finally recrystallising the precipitate from ether (Duquesnel, *C. R.* 73, 207; Wright, *C. J.* 31, 150).

Properties.—Crystallises in rhombic or hexagonal plates. Soluble in alcohol, ether, benzene, very soluble in chloroform, insoluble in light petroleum. Extremely poisonous; the minutest particles, inhaled or blown into the eye produce excessive irritation (W., *C. J.* 31, 154; Wright a. Luff, *C. J.* 33, 325). Lævogyrate (D.).

***Reactions.*—Slightly alkaline; forms well-crystallised salts. Resolved by heating with alcoholic KOH into benzoic acid and aconine:**

$$C_{33}H_{43}NO_{12} + H_2O = C_7H_6O_2 + C_{26}H_{39}NO_{11};—$$

partly also in the same manner by dilute mineral acids, but another portion is at the same time resolved into water and **apoaconitine.** Acetic and benzoic anhydrides convert it into **acetyl** and **benzoyl-apoaconitine** (W. a. L.). The *hydrobromide* forms crystals containing $C_{33}H_{43}NO_{12},HBr,2\frac{1}{2}H_2O$; the *hydrochloride* $C_{33}H_{43}NO_{12},HCl,3H_2O$, forms with auric chloride the salt $C_{33}H_{43}NO_{12},HCl,AuCl_3$, which separates in pale yellow amorphous flakes very slightly soluble in water (W.).

Apoaconitine $C_{33}H_{41}NO_{11}$.[186°].—Formed, together with benzoic acid and aconine, by prolonged boiling of aconitine with sulphuric acid (5 p.c.) or with a saturated solution of tartaric acid. The benzoic acid which separates is dissolved out by ether and the apoaconitine is precipitated by sodium carbonate, while the aconine remains dissolved. Crystals soluble in ether. As poisonous as aconitine. The *hydrobromide* $C_{33}H_{41}NO_{11},HBr.2\frac{1}{2}H_2O$ is crystalline (W. a. L.).

Acetyl-apoaconitine $C_{33}H_{40}AcNO_{11}$.[181°]. Soluble in ether, separates therefrom in small crystals. Dissolves easily in acids, forming amorphous salts (W. a. L.). *Benzoylapoaconitine* $C_{40}H_{45}NO_{12} = C_{33}H_{40}BzO_{11}$, obtained by heating aconitine or aconine with Bz_2O, is indistinctly crystalline, softens at about 130°, forms amorphous salts. Nitrate nearly insoluble (W. a. L.).

Aconine $C_{26}H_{39}NO_{11}$ [130°]. Formed, together with benzoic acid, by the action of aqueous alkalis, or more completely by that of alcoholic NaOH, on aconitine (*v. sup.*). V. sol. water, alcohol, alkalis and chloroform, insol. ether. Amorphous. Reduces gold and silver salts at ord. temp., Fehling's solution when heated.

Salts.—$3C_{26}H_{39}NO_{11},2HCl$ and $B'_7H_2SO_4$ are amorphous and probably only mixtures. $B'HClAuCl_3$ is a yellow flocculent pp. $B'HIHgI_2$ is a white flocculent pp. (W. a. L.).

Apoaconine, $C_{26}H_{37}NO_{10}$ is formed by heating the hydrochloride of aconine at 140°. $C_{26}H_{37}NO_{10}HCl$ is amorphous, soluble in water, precipitated by alkalis.

2. **Picroaconitine** $C_{31}H_{45}N_{10}$.—Found by T. B. Groves in a commercial aconite root, supposed to be that of *A. Napellus.* Amorphous varnish, having a bitter taste, but not producing any prickly sensation on the tongue. Not poisonous. Does not melt at 100°. Salts crystallise well. The *hydrochloride* contains $C_{31}H_{45}NO_{10}HCl,\frac{3}{2}H_2O$. The *gold salt* $B'HClAuCl_3$, is a canary-yellow amorphous precipitate very slightly soluble in water (W.).

Picroaconine $C_{24}H_{41}NO_9$. Formed, together with benzoic acid, by the action of alcoholic KOH on picroaconitine. Closely resembles aconine. Forms $C_{24}H_{41}NO_9HIHgI_2$ (W. a. L.).

3. **Pseudaconitine** $C_{36}H_{49}NO_{12}$ [104°–105°]. The chief basic constituent of the root of *Aconitum ferox*, from which it is obtained by exhausting with alcohol and sulphuric acid (0·05 p.c. of the weight of the alcohol), or with methylated spirit (640 c.c.) containing a little HClAq (1 c.c.), leaving the alcohol to evaporate, precipitating the remaining solution with ammonia, dissolving the precipitate in ether, and evaporating. The crystals which separate are purified by

recrystallisation from a mixture of ether and light petroleum, or by means of the nitrate.

Properties.—More soluble in alcohol and ether than aconitine; crystallises in transparent needles and sandy crystals; remains syrupy after rapid evaporation. The air-dried base contains 1 mol. H_2O, given off at 80° in a stream of air, more quickly at 100°; decomposes, with separation of water at 130°–140°. Decomposed by alcoholic soda at 100° into pseudaconine and veratric acid:

$$C_{36}H_{49}NO_{12} + H_2O = C_{27}H_{41}NO_9 + C_9H_{10}O_4$$

at 140° into veratric acid and apopseudaconine, $C_{27}H_{39}NO_8$. By mineral acids it is resolved into water and apopseudaconitine; with acetic acid it forms acetylapopseudaconitine. Salts mostly amorphous; nitrate $C_{36}H_{49}NO_{12}\,NO_3H\,3H_2O$, crystalline. $B'HClAuCl_3$ crystallises from alcohol in small needles, slightly soluble in cold alcohol. $B'HIHgI_2$ is an amorphous flocculent pp. (W. a. L.)

Apopseudaconitine $C_{36}H_{47}NO_{11}$ [103°]. Formed, together with pseudaconine and veratric acid, by heating pseudaconitine with dilute mineral acids, or with veratric acid alone when pseudaconitine is heated at 100° with a saturated aqueous solution of tartaric acid. Crystallises from ether in the same forms as pseudaconitine. The *nitrate* is crystalline. The *aurochloride* $C_{36}H_{47}NO_{11}HClAuCl_3$ crystallises from alcohol in small needles (Wright a. Luff).

Acetyl-apopseudaconitine $C_{36}H_{46}AcNO_{11}aq.$ Formed by heating pseudaconitine at 100° with acetic anhydride or glacial acetic acid, and separated by agitation with ether. Crystalline. Nitrate and aurochloride crystalline. *Benzoyl-apopseudaconitine* $C_{36}H_{46}BzNO_{11}aq.$ Indistinctly crystalline. Nitrate and aurochloride crystallise, the latter from alcohol in anhydrous rosettes (W. a. L.).

Pseudaconine. $C_{27}H_{41}NO_9$ [100°]. Formed, together with veratric acid, by heating pseudaconitine with dilute mineral acids, or better with alcoholic soda. Light yellow varnish, moderately soluble in water forming a strongly alkaline bitter solution, which, however, does not produce any prickly sensation on the tongue. Soluble in ether. Forms amorphous salts. Reduces silver solution and alkaline copper solution when heated.—$C_{27}H_{41}NO_9HIHgI_2$ is a white amorphous precipitate (W. a. L.).

Apopseudaconine $C_{27}H_{39}NO_8$. Formed, together with veratric acid, by heating pseud aconitine with alcoholic soda at 140°. Closely resembles pseudaconine.—$C_{27}H_{37}Ac_2NO_8$ is an amorphous varnish melting below 100°, sparingly soluble in water. Salts amorphous. $C_{27}H_{37}Bz_2NO_8$ is nearly insoluble in water (W. a. L.).

4. Japaconitine. $C_{66}H_{88}N_2O_{21}$. In the root of *Aconitum Japonicum.* Prepared by exhausting the root with alcohol containing 1 p.c. tartaric acid, concentrating the extract when adding water, and repeatedly agitating the filtered liquid with ether to remove resinous constituents; precipitating the alkaloids with sodium carbonate; agitating it with ether; dissolving it in aqueous tartaric acid; again precipitating it with Na_2CO_3, and dissolving in ether. The resulting solution when left to evaporate deposited crystals which after being freed from adhering syrup, were re-crystallised from ether, and after repeated fractional crystallisation gave by analysis numbers agreeing with the formula $C_{66}H_{88}N_2O_{21}$, confirmed by the analysis of the gold-salt. The *hydrobromide* $C_{66}H_{88}N_2O_{21}\,2HBr\,5H_2O$, and the *nitrate* crystallise well (Wright a. Luff, *C. J.* 35, 387).

Japaconine, $C_{26}H_{41}NO_{10}$, is obtained, together with benzoic acid, by heating japaconitine with alcoholic potash: $C_{66}H_{88}N_2O_{21} + 3H_2O = 2C_7H_6O_2 + 2C_{26}H_{41}NO_{10}$. Yellowish varnish, easily soluble in ether, alcohol, and chloroform; insoluble in water. Forms a mercuriodide $C_{26}H_{41}NO_{10}HHgI_2$.

Japaconitine and japaconine heated with benzoic anhydride yield the same product, viz. $C_{26}H_{39}NO_7(OC_7H_5O)_4$, which is flocculent, dissolves in ether, and does not crystallise. Salts non-crystalline, nitrate very sparingly soluble in water (W. a. L.).

5. **Lycaconitine** $C_{27}H_{34}N_2O_6 2aq.$ A non-crystallisable alkaloid obtained from wolf's bane, *aconitum lycoctonum* (Dragendorff a. Spohn, *J. Ph.* [5] 10, 361; *C. J.* 48, 403). If heated with water under pressure it is converted into crystalline *lycoctonic acid,* $C_{17}H_{18}N_2O_7$, and two alkaloids, *lycaconine* and acolyctine.

6. **Myoctonine,** $C_{27}H_{30}N_2O_8 5aq.$ Is an amorphous alkaloid also present in *A. lycoctonum.*

H. W.

ACONITIC ACID $C_6H_6O_6$ *i.e.* $C_3H_3(CO_2H)_3$ or $CO_2H.CH_2.C(CO_2H) : CH.CO_2H$ [186°–187°] S. 18·6 at 13°. S. (80 p.c. alcohol) 50 at 12°. *Equisetic acid, citridic acid.* Occurs as calcium salt in the roots and leaves of monk's-hood (*Aconitum Napellus*) and other aconites, in the herb of *Delphinium Consolida* collected after flowering (Wicke, *A.* 90, 98); in the horse-tail (*Equisetum fluviatile*) (Baup, *A.* 77, 293); in millefoil (Zanon, *A.* 58, 21; Hlasiwetz, *J. pr.* 72, 429); in the juice of the sugar-cane (Behr, *B.* 10, 351), and in that of sugar-beet (O. v. Lippmann, *B.* 12, 1649); as calcium and potassium salt in the leaves of *Adonis vernalis* (Linderos, *A.* 182, 365).

Formation.—1. By the action of heat on citric acid, or by prolonged boiling of that acid with hydrochloric acid: $C_6H_8O_7 - H_2O = C_6H_6O_6$ (Dessaignes, *C. R.* 42, 491); more quickly by heating citric acid with HCl in a sealed tube at 130°–140° (Hergt, *J. pr.* [2] 8, 372), or by boiling it with HBr (Mercadante, *G.* 7, 248).—2. In small quantity, together with citraconic acid, by heating citric acid with HI in a sealed tube (Kämmerer. *A.* 139, 269).

Preparation.—Citric acid, in portions of 100 grams each, is heated in small flasks provided with bent distillation-tubes ½ met. long, till the whole tube is lined with small oily drops, and the residue is heated on a water bath with 15 g. water till it solidifies to a crystalline mass. On pulverising this mass and treating it with pure ether, aconitic acid dissolves and citric acid is left behind (Pawolleck, *A.* 178, 150). Hunäus (*B.* 9, 1751) heats citric acid at 140° for a day in a stream of HCl-gas, dissolves the product in a small quantity of water, evaporates, and treats the residue by Pawolleck's method.

Properties and *Reactions.*—Crystallises in small four-sided plates, melting at 187° and resolved at the same time into CO_2 and itaconic acid $C_5H_6O_4$; also when heated with water at

180° (Pebal, *A.* 98, 94). Dissolves easily in absolute ether, whereby it is distinguished from citric acid. Converted by *sodium-amalgam* into tricarballylic acid $C_6H_8O_6$ (Hlasiwetz, *J.* 1864, 396). Unites with fuming HBr, at 100°, forming bromocitric acid $C_6H_7BrO_7$, and with hypochlorous acid, forming chlorocitric acid $C_6H_7ClO_7$. The calcium salt fermented with cheese yields succinic acid (Dessaignes, *C. R.* 31, 432).

Salts. The acid is tribasic. The NH_4, K, Na, Mg and Zn salts dissolve readily in water, the rest are insoluble or only sparingly soluble. The soluble aconitates form, with lead and silver solutions, white flocculent precipitates (distinction from fumaric and maleic acids).

$(NH_4)H_2A'''$: nodules or laminæ. S. 15·4 at 15°.—$(NH_4)_2HA'''$.—K_3A'''2aq. S. 9 at 15° (Baup, A. 77, 299). Slender, silky, very deliquescent needles; lose aq at 100° and aq at 190° (Guinochet, *C. R.* 94, 455).—K_2HA''' 2aq. S. 37·7 at 16°: small prisms (G.).—KH_2A'''. S. 11 at 17°; minute elongated prisms.—Na_3A''' 2aq: retains its water in a current of air at 60° but gives it up at 15° *in vacuo.*—Li_3 A''' 2aq: v. sol. water; solution is alkaline.—$CaHA'''$aq: gummy; v. sol. water.—$Ca_3A'''_2$ 3aq: gummy; v. sol. cold water, but at 80°-100° this solution deposits rhombic prisms, sl. sol. cold water. The latter gradually dissolve, changing to the gummy variety.—$Ca_3A'''_2$ 6aq. S. 1·01 at 15° (B.).—$Sr_3A'''_2$ 3aq. S. ·625 at 16° (G.). Ppd. on boiling the solution.—$BaH_4A'''_2$: prisms. S. 4·2 at 17° (G.).—$Ba_3A'''_2$ 3aq: gelatinous pp. got by adding $BaCl_2$ to aconitic acid or a solution of an aconitate.—$Mg_3A'''_2$ 3aq. S. 10·4 at 17°. Elongated octahedra (G.).—$Co_3A'''_2$ 3aq. S. 3·5 at 16°. Pink powder.—$Ni_3A'''_2$aq. Pp. changed by long boiling to $Ni_3A'''_2$ 6aq.—$Cd_3A'''_2$ 6aq. S. ·113 at 17°. Prisms.—$Zn_3A'''_2$3aq: insoluble in water.—$Pb_3A'''_2$ 3aq(?): flocculent precipitate (Buchner).—$Pb_3A'''_2 2PbO 2H_2O$: obtained by prolonged boiling of the NH_4-salt with basic lead acetate (Otto, *A.* 127, 180).—$Mn_3A'''_2$ 12aq: small rose-coloured octahedra, slightly soluble in water (Baup).—Ag_3A''' prepared by adding $AgNO_3$ to the normal ammonium salt, is a thick flocculent precipitate, becoming crystalline on drying; slightly soluble in water.

A solution of aconitic acid mixed with ferric chloride is precipitated by ammonia, but the presence of citric acid even in small quantity prevents the precipitation (*Bn.* 1, 648).

Ethers.—The ethers of aconitic acid are formed by heating the acetyl derivatives of the corresponding citric ethers, $C_3H_4(OAc)(CO_2R)_3$, at 250°-280°, acetic acid being split off; yield 75 p.c. of the theoretical (Anschütz a. Klingemann, B. 18, 1953).

Me_3A''' (271°) (Hunæus, *B.* 9, 1750); (161°) at 14 mm. (A. a. K.) From aconitic acid, MeOH, and HCl (H.).

Et_3A''' (275°) (Mercadante, *G.* 1, 248); (252°) at 250 mm. (Conen, *B.* 12, 1655); (171°) at 14 mm. (A. a. K.). S.G. $\frac{20}{4}$ 1·1064 (C.); ^{14} 1·074 (Crasso, *A.* 34, 59). From tetra-ethyl citrate and PCl_5 at 100° (Conen).

Pr_3A''' (195°) at 13 mm. (A. a. K.)

Di-anilide. [217°]. Yellow needles; formed by boiling aqueous aniline aconitate (Michael, *B.* 19, 1374).

Iso-aconitic ether
$CO_2Et.CH{:}CH.CH(CO_2Et)_2$(?)(248°) S.G. $\frac{15}{15}$ 1·0505. A product of the action of hot HCl upon di-carboxy-glutaconic ether (*q. v.*). An oil; sol. alcohol or ether (Conrad a. Guthzeit, *A.* 222, 255).

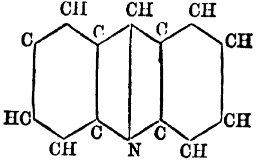
Pseudo-aconitic acid
$CO_2H.CH_2.CH(CO_2H).C''.CO_2H$ [217°]
Formed at 180° from propylene tetra-carboxylic acid (*q. v.*), obtained from bromo-maleic ether and sodium malonic ether (Schacherl, *A.* 229, 95).

Salt.—$Ba_3A'''_2$aq. H. W.

ACORIN $C_{36}H_{60}O_6$. A glucoside extracted from the common reed (*Acorus calamus*). Sol. alcohol or ether; ppd. by benzene from its ethereal solution (A. Faust, *Bl.* [2] 9, 392; Thoms, *Ar. Ph.* [3] 24, 465).

ACRALDEHYDE *v.* ACROLEÏN.

ACRIDINE $C_{13}H_9N$ *i.e.*



M. w. 179. [106°] (Bernthsen); [111°] (Fischer a. Körner). V. D. 6·10 (Graebe, *B.* 5, 15).

Occurrence.—In coal tar (Graebe a. Caro, *A.* 158, 265). The portion that boils between 300° and 360° is extracted with H_2SO_4Aq and the extract ppd. by $K_2Cr_2O_7$.

Formation.—1. By heating formyl-diphenylamine (23 g.) with $ZnCl_2$ (45 g.) at 190°-220°:

$$H.CO.N(C_6H_5)_2 = C_{13}H_9N + H_2O.$$

2. From crystallised oxalic acid, diphenylamine, and $ZnCl_2$ at 120°-260°.—3. From chloroform, diphenylamine, and $ZnCl_2$ or $AlCl_3$. In this way 2 g. of acridine can be got from 25 g. diphenylamine. It is better to heat chloroform (1 pt.) with diphenylamine (1 pt.), $ZnCl_2$ (1 pt.), and ZnO ($\frac{1}{2}$ pt.), for 8 hrs. at 200° (Fischer a. Körner, *B.* 17, 101). $(C_6H_5)_2NH + CCl_3H + ZnO = C_{13}H_9N,HCl + ZnCl_2 + H_2O$. — 4. By passing phenyl-*o*-toluidine through a red hot tube (Graebe, *B.* 17, 1370).—5. In small quantity (5 p.c.) by heating aniline and $ZnCl_2$ with *o*- or *p*- oxy-benzoic aldehyde or even with benzoic aldehyde (Möhlau, *B.* 19, 2451).

Preparation.—Heat formic acid (50 g. of S.G. 1·22) with diphenylamine (175 g.) and $ZnCl_2$ (100 g.) gradually from 150° to 270°, avoiding evolution of CO. Dissolve the product in alcohol, and pour into aqueous NaOH. Acridine and diphenylamine are in the alcoholic layer; evaporate this, and dissolve the residue in ether; shake the ether with dilute hydrochloric acid. The acridine is then in the acid solution. The yield is small (Bernthsen, *A.* 224, 3).

Properties.—Long needles (from much water) or prisms, $a:b:c$ = ·656 : 1 : ·335. Pungent odour and burning taste. The base and its hydrochloride attack the tongue even when in minute quantities. Volatile with steam. Very slightly soluble in water. Dilute solutions exhibit a characteristic greenish-blue fluorescence.

Salts.—(Bernthsen, *A.* 224, 3; *B.* 16, 1802; Graebe, *B.* 16, 2828; Medicus, *B.* 17, 196.)—B′HCl: yellow plates, soluble in water imparting a bluish-green fluorescence.—$B'_2H_2PtCl_6$: sparingly soluble minute yellow needles.—

B'_2HNO_2 3aq: [151°], yellow pp. got by adding sodium nitrite to a solution of an acridine salt. Long yellow silky needles; sl. sol. ether or cold water, m. sol. hot water, v. e. sol. alcohol; somewhat volatile with steam.—$B'_2H_2SO_3$: formed by adding aqueous SO_2 to a solution of the hydrochloride. Yellowish-red needles, v. sl. sol. water.—$B'HNaSO_3$: got by mixing solutions of sodium sulphite and acridine hydrochloride. Colourless, easily soluble, prisms.

Picrate. $C_{13}H_9NC_6H_2(NO_2)_3OH$. Minute yellow prismatic needles. Melts at a high temperature. V. sl. sol. cold alcohol, cold water or cold benzene. Boiling water partially decomposes it (Anschütz, *B.* 17, 438).

Acridine forms no carbonate.

Reactions.—1. $HgCl_2$ gives a yellow crystalline pp. $(C_{13}H_9N,HCl)_2HgCl_2$.—2. $K_2Cr_2O_7$ gives a yellow pp. $C_{13}H_9NH_2CrO_4$.—3. I dissolved in KIAq gives a brownish pp. $(C_{13}H_9NHI)_2I_2$.—4. *Reduced* in alcoholic solution by sodium amalgam to hydro-acridine which is soluble in alcohol; at the same time a white powder insoluble in alcohol is formed. *Hydro-acridine*, $C_6H_4<{CH_2 \atop NH}>C_6H_4$, is not a base. It forms prisms, [169°], sl. sol. cold alcohol, v. sol. hot alcohol or ether, insol. water. Sol. conc. H_2SO_4 and reppd. by water, unaltered. It is oxidised by Ag_2O or CrO_3 back to acridine.—5. $KMnO_4$ *oxidises* acridine to a quinoline di-carboxylic acid (acridinic acid) (Graebe a. Caro, *B.* 13, 99).

Octo-hydro-acridine (*acridine-octo-hydride*) $C_{13}H_{17}N$ [84°]. (320°). Colourless plates or tables.

Formed by heating acridine or hydroacridine with HI and P at 220°.—B′,HCl: colourless tables, soluble in hot water, sparingly in cold (Graebe, *B.* 16, 2831).

ACRIDINES.—Compounds having the general formula

$$C_6H_4<{CR \atop \overset{|}{N}}>C_6H_4.$$

They are characterised by basic properties, fluorescence in dilute solutions, capability of directly uniting with MeI, and of forming neutral dihydrides which may readily be reconverted into the original base. *v.* BUTYL-ACRIDINE, METHYL-ACRIDINE, and PHENYL-ACRIDINE. See also AMIDO-PHENYL-ACRIDINE, OXY-PHENYL-ACRIDINE, AMIDO-HYDRO-ACRIDINE KETONE.

ACRIDINIC ACID *v.* (*Py.* 2:3)-QUINOLINE-DI-CARBOXYLIC ACID.

ACRIDYL-BENZOIC ACID *v.* PHENYL-ACRIDINE CARBOXYLIC ACID.

ACROLACTIC ACID

$C_3H_4O_3$, *i.e.* $CHO.CH_2.CO_2H$ or $CH(OH):CH.CO_2H$. Formed by boiling ethyl β-chloro-acrylate $CHCl:CH.CO_2Et$, with baryta water (Pinner, *B.* 7, 250; *A.* 179, 91). The acid is a thick syrup. Its silver salt, AgA′, blackens quickly on exposure to light, and is m. sol. water.

ACROLEÏN C_3H_4O, *i.e.* $CH_2:CH.CHO$. *Acrylic aldehyde, Acraldehyde.* Mol. w. 56. (52·4°). V.D. 1·897. S. 2·5. $S.G.^{20}_{4}$ ·841; μ_β 1·4089; R_∞ 25·31 (Brühl).

Formation.—1. By oxidation of allyl alcohol $CH_2:CH.CH_2OH$, with platinum-black or chromic acid mixture.—2. By dehydration of glycerin, $C_3H_8O_3$, and therefore in the destructive distillation of fats.—3. By distillation of acetone dibromide; $C_3H_6OBr_2 = 2HBr + C_3H_4O$.—4. From di-iodacetone and silver cyanide (M. Simpson, *J. pr.* 102, 380).—5. By exploding ethylene with a large excess of oxygen, the carbon being partly oxidised to CO, which with the ethylene forms acraldehyde, $C_2H_4 + CO = C_3H_4O$. This effect, however, is produced only by nascent, not by ready-formed CO (E. v. Meyer, *J. pr.* [2] 10, 113).

Preparation.—Anhydrous glycerin (1 pt.) is distilled with $KHSO_4$ (2 pts.), and the vapour, after passing over calcium chloride and lead oxide to remove water and acrylic acid, is condensed by a freezing mixture (Aronstein, *A. Suppl.* 3, 180).—Obtained also in large quantity as a by-product in the preparation of œnanthaldehyde, from castor-oil (Schorlemmer).

Properties.—Mobile strongly refracting liquid. Vapour extremely irritating to the nose and eyes. Taste pungent and burning. It is readily converted into disacryl, a white amorphous body (isomeric or polymeric?), insoluble in water, alcohol, acids, and alkalis.

Reactions.—1. Oxidised quickly in the air, or by silver-solution to acrylic acid, in the latter case with formation of a silver speculum; by nitric acid to glycollic and oxalic acids (Claus. *A. Suppl.* 2, 118).—2. Converted by nascent *hydrogen* (Zn and HCl) into allyl alcohol, C_3H_6O, isopropyl alcohol, C_3H_8O, and acro-pinacone $2C_3H_4O + H_2 = C_6H_{10}O_2$ (Linnemann, *A. Suppl.* 3, 257).—3. With PCl_5 acroleïn yields allylene chloride $C_3H_4Cl_2$ (84·5°), the isomeric dihydrochloroglycide or β-epidichlorhydrin (102°), and trichlorhydrin $C_3H_5Cl_3$ boiling at 152°–156° (Geuther, *Z.* 1865, 24).—According to Romburgh (*Bl.* [2] 36, 549) the three liquids are allylidene chloride $C_3H_4Cl_2$ (85°), its isomeride, (110° cor.), and β-chloro-allyl alcohol $CHCl:CH.CH_2OH$ (153° cor.).—4. *Bromine* forms di-bromo-propionic aldehyde (*q. v.*).—5. Acroleïn heated with *ethyl-alcohol* and its homologues and a little acetic acid, yields glycerides; *e.g.* triethylin $C_3H_5(C_2H_5)_3O_3$, from 1 vol. C_3H_4O and 1 vol. alcohol and 0·5 vol. acetic acid; trimethylin $C_3H_5(CH_3)_3O_3$, from 1 vol. C_3H_4O, 3 vol. methyl alcohol, and 0·5 vol. acetic acid; and triamylin $C_3H_5(C_5H_{11})_3O_3$, in like manner. On passing HCl-gas into a mixture of acroleïn and 2 vol. absolute alcohol, diethylchlorhydrin $C_3H_5(C_2H_5)_2ClO_2$ is obtained as a heavy oil having a sweetish ethereal odour and S. G. 1·03 at 10·5° (Alsberg, *J.* 1864, 494).—6. Acroleïn acts strongly on *aniline*, forming diallylidene-di-phenyl-di-amine, $(C_6H_5)_2(C_3H_4)_2N_2$ (Schiff, *J.* 1864, 414).

Combinations.—1. **With Sodium Hydrogen Sulphite** by direct combination $C_3H_4O,2NaHSO_3 = CH_3.CH(NaSO_3).CH(OH)(NaSO_3)$. Crystalline nodules. With acids gives off SO_2 but no acroleïn. By NH_3 and $BaCl_2$ only half the sulphurous acid is precipitated as $BaSO_3$, the α-sulphopropionic aldehyde remaining in solution. Sodium amalgam converts it into oxypropane sulphonic acid. Silver oxide oxidises it to α-sulpho-propionic acid (Max Müller, *B.* 6, 1441.—*Bn.* 360).

2. **With Acetic Anhydride.** $C_3H_4O,C_4H_6O_3$ or $C_3H_4(OAc)_2$. Formed by direct combination at 100°. Liquid (180°). $S.G.^{22}$ 1·076 (Hübner a. Geuther, *A.* 114, 47).

3. **With Acetyl Chloride.** $C_3H_4O,2C_2H_3OCl$. Liquid boiling at 140°–145° (Aronstein).

4. **With Ethyl Chloride.** $CH_2:CH.CHCl(OC_2H_5)$. Formed together with acroleïn-acetal, by the action of sodium ethylate on *allylidene chloride, $CH_2:CH.CHCl_2$* at 120°. Liquid. (115°–120°).

5. **With Ethyl Alcohol.** $C_5H_{10}O_2$ *i.e.* $CH_2:CH.CH(OH)(OC_2H_5)$. From acroleïn hydrochloride and sodium ethylate:

$$CH_2:CH.CHO,HCl + NaOEt = NaCl + CH_2:CH.CH(OH)OEt.$$

Liquid boiling, with partial decomposition at 130°. S.G. ^{0} 0·946. Soluble in water, alcohol and ether (Geuther a. Cartmell, *A.* 112, 3).

6. With **ammonia**, acroleïn forms a condensation-product $C_6H_9NO = 2C_3H_4O + NH_3 - H_2O$, prepared by passing the vapour of anhydrous acroleïn into alcoholic ammonia (Hübner a. Geuther, *A.* 114, 35), or more readily by passing the vapour of crude acroleïn into aqueous ammonia, expelling the excess of ammonia by a gentle heat and precipitating the remaining liquid with a mixture of ether and alcohol (Claus. *A.* 130, 186).—Red amorphous body easily soluble in water and in acids, sparingly in hot alcohol, insoluble in cold alcohol and in ether. Converted by dry distillation, first into a non-volatile oxygenated base (Claus. *A.* 158, 222), then into **picoline** and water (Baeyer, *A.* 155, 283). Acroleïn-ammonia unites directly with bases, forming brown amorphous salts. The *platinochloride* $(C_6H_9NOHCl)_2PtCl_4$ is a yellow amorphous pp.

Polymerides. 1. **Metacroleïn** $(C_3H_4O)_3$. [50°]. V.D. 5·9. Formed with evolution of hydrogen, when acroleïn hydrochloride is heated with potassium hydroxide (not NaOH). Needle-shaped crystals lighter than water, having an aromatic odour. Partly reconverted by distillation into acroleïn. Volatilises undecomposed with aqueous vapour. Insoluble in cold, sparingly soluble in hot water, easily in alcohol and ether. Exerts only a feeble reducing action on ammoniacal silver solution. Not affected by dilute alkalis, but changed more or less into acroleïn by heating with mineral acids. Does not combine with ammonia. Unites with dry HCl-gas forming β-chloropropionic aldehyde $CH_2Cl.CH_2.CHO$ (Geuther a. Cartmell, *A.* 112, 3).

2. **Acroleïn resin.** Formed by heating acroleïn for a week with 2–3 vol. water at 100°, as a brown resin which begins to melt at 100°, is moderately soluble in hot water, easily in alcohol and in ether. Heated with ammoniacal silver solution, it reduces the silver in specular form. Reconverted into acroleïn at 100° (G. a. C.).

3. **Hexacroleïc acid** $C_{18}H_{24}O_6$. Formed by treating acroleïn with alcoholic or aqueous potash or with moist silver oxide. Yellow amorphous body, insoluble in water, easily soluble in alkalis, alcohol, and ether. Has a slight acid reaction. **Salts:** $NaC_{18}H_{23}O_6$: brown and amorphous. $Ca(C_{18}H_{23}O_6)_2$: yellow flocculent precipitate, insoluble in water and in alcohol. *Barium salt*; amorphous; decomposed by CO_2 (Claus. *A. Suppl.* 2, 120). H. W.

ACROLEÏN-DIPHENYLAMINE *v.* DIPHENYL-AMINE-ACROLEÏN.

ACROLEÏN-UREA $C_4H_8N_2O$, *i.e.* $CON_2H_2(C_3H_4)$. Formed by the action of acroleïn on urea in alcoholic solution (Leeds, *A.C.J.* 4, 58; *B.* 15, 1580). White powder; sol. alcohol, ether, or CS_2. Other bodies are also formed (Schiff, *A.* 151, 206; *B.* 15, 1898).

ACROLEÏN-*m*-XYLIDINE *v.* *m*-XYLIDINE ACROLEÏN.

ACROPINACONE $C_6H_{10}O_2$, *i.e.* $CH_2:CH.CH(OH).CH(OH).CH:CH_2$ (160°–180°) S.G.^{17} ·99. Formed by action of zinc and dilute H_2SO_4 upon acroleïn (Linnemann, *A. Suppl.* 3, 268; L. Henry, *J. pr.* [2] 9, 477). It is extracted with ether. It turns brown in air. V. sol. alcohol or ether, insol. water.

ACROTHIALDINE. $C_9H_{13}NS_2 5aq$. A base produced by the action of ammonium sulphydrate on acroleïn at 0° (Schiff, *Bl.* [2] 8, 444). Insol. water, v. sl. sol. alcohol, ether, or CS_2.

ACRYL-COLLOIDS *v.* β-BROMO-ACRYLIC ACID.

ACRYL-ALDEHYDO-PHENOXY-ACETIC ACID $C_{11}H_{10}O_4$ *i.e.* $CHO.CH:CH.C_6H_4.O.CH_2.CO_2H$ *o* [153°]. *m* [100°]. *p* [182°]. These three acids are prepared by adding a cold aqueous solution of aldehyde to a dilute solution of sodium *o*-aldehydo-phenoxy-acetate at 50° (Elkan, *B.* 19, 3018).

ACRYLIC ACID $C_3H_4C_2$, *i.e.* $CH_2:CH.CO_2H$. Mol. w. 72. [8°] (140°) (Linnemann, *A.* 171, 294).

Formation.—1. By oxidation of acroleïn (p. 61).—2. By heating β-iodopropionic acid with sodium ethylate: $CH_2I.CH_2.CO_2H + NaOEt = NaI + EtOH + CH_2:CH.CO_2H$. (v. Schneider a. Erlenmeyer, *B.* 3, 339).—3. By heating β-iodopropionic acid with lead oxide.—4. Together with propyl alcohol and other products, by heating allyl alcohol with KOH (Tollens, *Z.* [2] 6, 457).—5. From iodoform and sodium ethylate (Butlerow, *A.* 114, 204).—6. By debromination of α-β-dibromopropionic acid with zinc-dust,

$$CH_2Br.CHBr.CO_2H - Br_2 = CH_2:CH.CO_2H.$$

7. By heating dichlorallylene with water:

$$CCl_2:C:CH_2 + 2H_2O = 2HCl + CH_2:CH.CO_2H$$

(Pinner, *B.* 7, 66).—8. By the distillation of hydracrylates $C_3H_6O_3 = C_3H_4O_2 + H_2O$ (Beilstein, *A.* 122, 372).

Preparation.—Acroleïn mixed with 3 vol. water is poured upon recently precipitated silver oxide suspended in water in a vessel protected from light; the liquid is heated to boiling; sodium carbonate added to slight alkaline reaction; and the mass, after evaporation to dryness, is treated with dilute sulphuric acid. The liquid is filtered (hexacroleïc acid and reduced silver remaining on the filter) and the filtrate is distilled, acrylic acid then passing over (Claus. *A. Suppl.* 2, 117).

Properties.—Colourless liquid having a pungent odour like that of acetic acid; solidifying at low temperatures; miscible with water.

Reactions.—1. Converted by *sodium-amalgam* and by boiling with *zinc* and dilute *sulphuric acid* into propionic acid (Linnemann, *A.* 125, 317).—2. Fusion with KOH gives formic and acetic acids: $C_3H_4O_2 + 2H_2O = CH_2O_2 + C_2H_4O_2 + H_2$ (Erlenmeyer, *A.* 191, 376).—3. Unites directly with *bromine* forming αβ-dibromopropionic acid, $CH_2Br.CHBr.CO_2H$, and with *hydriodic acid*, forming β-iodopropionic acid, $CH_2I.CH_2.CO_2H$ (Wislicenus, *A.* 166, 1).—4. Its alcoholic solution saturated with HCl, yields ethyl β-chloropropionate, $CH_2Cl.CH_2.CO_2C_2H_5$ (Linnemann, *A.* 163, 96).—5. Unites with *hypochlorous acid*, forming β-chlorolactic acid

$CH_2:CH.CO_2H + ClOH = CH_2Cl.CHOH.CO_2H$ (Mellikow, *B.* 12, 2227; 13, 2154).

Salts.—All except the silver salt are easily soluble in water. *Give off part of their acid at* 100°, leaving basic salts; the K-, Ba-, and Zn-salts decomposing in this manner even at ordinary temperatures.—$KC_3H_3O_2$ is very deliquescent (Clausius).—NaA', microscopic needles. 100 pts. cold alcohol dissolve 0·7 pt. of this salt (Zotta, *A.* 192, 105). Dissolves easily in 90 p.c. alcohol. Melts with decomposition above 250° (Linnemann). Converted by heating with aqueous soda at 100° into the isomeric hydracrylic acid $CH_2OH.CH_2.CO_2H$ (Linnemann, *B.* 8, 1095).—CaA'_2: needles (Caspary a. Tollens).—SrA'_2: small rhombic plates very soluble in water.—ZnA'_2: small scales (Clausius).—PbA'_2: shining needles soluble in alcohol.—AgA': flocculent precipitate crystallising from boiling water in prisms (Caspary a. Tollens, *A.* 167, 240).

Ethers.—MeA' (80·3°) (Weger) S.G.$\frac{0}{}$ ·934. From methyl α-β-di-bromo-propionate, MeOH, Zn and H_2SO_4 (C. a. T.; Kahlbaum, *B.* 13, 2319).—EtA' (98·5°) (W.); (101·5°) (C. a. T.). From ethyl α-β-di-bromo-propionate, EtOH, Zn and H_2SO_4.—PrA' (122·9°)(W.). From propyl α-β-di-bromo-propionate, PrOH, Zn and H_2SO_4.—*Allyl ether.* C_3H_5A' (119°-124°) (C. a. T.).

Other derivatives of acrylic acid are described as: BROMO-ACRYLIC ACIDS, CHLORO-ACRYLIC ACIDS, CHLORO-BROMO-ACRYLIC ACID, AMIDO-ACRYLIC ACID, BROMO-IODO-ACRYLIC ACID, IODO-ACRYLIC ACID. See also HYDRACRYLIC ACID.

Paracrylic Acids $(C_3H_4O_2)_n$.—An acid probably having this composition is formed by the action of potassium cyanide on ethyl α-chloro-propionate at 150°. Short prisms melting at 180°-182°. Gives a brown red pp. with ferric chloride (Karetnikoff, *J. R.* 9, 116).—Another paracrylic acid is formed by boiling aqueous β-iodopropionic acid with excess of silver oxide, till the solution becomes coloured, and metallic silver begins to separate. The same acid is formed when hydracrylic acid $C_3H_6O_3$ is left in contact for several days with 1 mol. bromine.—Small crystals melting at 69°; insol. in water, slightly sol. in cold, easily in hot, alcohol. Easily takes up HI at 157° and is converted into β-iodo-propionic acid.—The sodium salt is indistinctly crystalline, deliquescent, does not melt at 180°. The lead salt is soluble in water (Klimenko, *J. R.* 12, 102).

Di-acrylic acid $C_6H_8O_4$.

At 250° sodium hydracrylate is decomposed into water, sodium acrylate, and sodium di-acrylate. On treating this mixture with water it becomes very hot, and the sodium di-acrylate takes up aq being converted into para-adipomalate, $Na_2C_6H_8O_5$. The latter is thrown down as a viscid syrup when an equal volume of alcohol is added. At 200°-250° it loses aq, changing to sodium di-acrylate, an amorphous deliquescent mass, which becomes warm when breathed upon, combining again with aq. **Salts.**—Na_2A''.—BaA''.—CaA'': from calcic hydracrylate at 220° (Wislicenus, *A.* 174, 285).

Para-adipomalic acid is a syrup. It is reduced by HI to para-adipic acid $C_6H_{10}O_4$. **Salts.**—$Na_2C_6H_8O_5$ aq.—BaA''.—CuA'' aq.—PbA''. All are amorphous. H. W.

ACTINOMETER.—Instrument for measuring chemical intensity of light. *V.* PHYSICAL METHODS, sect. OPTICAL.

ADENINE $C_5H_5N_5 3aq$. Occurs amongst the decomposition-products of the contents of all growing animal and vegetable cells. Formed, amongst other products, by boiling nucleïn with dilute H_2SO_4.

Long rhombic needles (from NH_3Aq. (V. sol. hot water, and in NaOHAq, v. sl. sol. Na_2CO_3Aq. Neutral to litmus. Insol. ether or $CHCl_3$.—By nitrous acid it is converted into hypoxanthine (Kossel, *B.* 18, 79, 1928; *H.* 10, 248). $C_5H_3Ag_2N_5$: insol. NH_3Aq. $(C_5H_5N_5)_2H_2SO_4 2Aq$. Sl. sol. water.

ADIPIC ACID $C_6H_{10}O_4$, *i.e.* $CO_2H.CH_2.CH_2.CH_2.CH_2.CO_2H$. Mol. w. 146. [149°]. S. 1·44 at 15°; S. (ether) ·633 at 19° (Dieterle a. Hell, *B.* 17, 2221); S. 7·73 at 18° (Wirz, *A.* 104, 257).

Formation.—1. By the oxidising action of nitric acid on sebacic acid, and on natural fats, *e.g.* hog's lard, cocoanut oil, &c.—the first product of the action being sebacic acid, which by further oxidation is converted into adipic acid (Laurent, *A. Ch.* [2] 66, 166; Bromeis, *A.* 35, 105; Malaguti, *A. Ch.* [3] 16, 84).—2. By the action of HI and phosphorus at 140° on mucic acid (Crum Brown, *A.* 125, 19), or saccharic acid (De la Motte, *B.* 12, 1572).—3. From muconic acid $C_6H_6O_4$ and sodium-amalgam (Marquardt, *B.* 2, 385).—4. From β-iodopropionic acid and silver at 100°-160°; $2(CH_2I.CH_2.CO_2H) + Ag_2 = 2AgI + (CH_2)_4(CO_2H)_2$ (Wislicenus, *A.* 149, 221). 5. By reduction of di-acetylene di-carboxylic acid, $CO_2H.C:C.C:C.CO_2H$, or of hydro-muconic acid, $C_4H_6(CO_2H)_2$, with sodium-amalgam (Baeyer, *B.* 18, 680).—6. By heating butane-ω-tetra-carboxylic acid (Perkin, *B.* 19, 2040).

Preparation.—Sebacic acid is boiled with nitric acid, whereby it is converted into a mixture of adipic and succinic acids, which are soluble in water. The nitric acid is then evaporated off, and the residue crystallised from water. It is then fused and the solidified mass is pulverised and treated with ether, which dissolves the adipic acid, leaving a small quantity of succinic acid (Arppe, *Z.* 1865, 300).

Properties.—Monoclinic laminæ, flat needles, or feathery groups of needles. Sparingly soluble in cold water, freely in alcohol and ether. It has a tendency to form supersaturated solutions. Converted into butane by distilling with large excess of CaO (Hanriot, *C. R.* 101, 1156).

Salts.—The *ammonium salt* $(NH_4)_2A''$ forms monoclinic crystals resembling augite; $a:b:c = ·688:1:·979$; $\beta = 82°14'$ (*A.* 217, 143). S. 40 at 14°. At 150° it gives off all its NH_3.—$Na_2A''2aq$.—$Na_2A''\frac{1}{2}aq$: very soluble pearly plates.—K_2A''.—BaA'': white pp. S. 12·04 at 12°; 7·47 at 100°. $SrA''\frac{1}{2}aq$.—CaA''aq.—CaA''2aq: minute needles (from alcohol), giving up their water at 100° (Laurent, *C. R.* 31, 351).—MgA''4aq: prisms. S. 25 at 15°.—ZnA''2aq.—CdA''2aq.—CuA''aq.—CuA''2aq.—PbA'': small glistening plates, S. ·021 at 16°.—HgA'': white crystalline pp.—Ag_2A'': small glistening plates, S. ·016 at 14°.—The ferric salt is a brown-red insoluble pp. For more detailed description of salts *v.* Dieterle a. Hell, *B.* 17, 2221.

Ethyl ether.—Et_2A'' (245°) (Arppe, *Z.* 1865, 302).

Amide $C_4H_8(CO_2NH_2)_2$ [220°] S. ·44 (Henry, *Bl.* 48, 618).—*Dimethyl-amide* $C_4H_8(CO_2NHMe)_2$ [151°–153°] (H.).

Derivatives of adipic acid v. BROMO-ADIPIC ACID, OXY-ADIPIC ACID. H. W.

Para-adipic Acid.—Formed by the action of HI on paradipimalic acid, $C_6H_{10}O_5$—a decomposition product of sodium hydracrylate *v. di*-ACRYLIC ACID.—Syrupy.—$ZnC_6H_8O_4,3H_2O$. Viscid flocculent pp. (Wislicenus, *A.* 174, 295). H. W.

Iso-adipic acid $C_4H_8(CO_2H)_2$. [192°]. S. 1 at 22°. A product of the action of bromine on the sulphate of cyanethine (*q. v.*). The product is extracted with ether; on evaporation this leaves an oil which reacts violently with strong NH_3, forming crystals of the amide of butane dicarboxylic acid, $C_4H_8(CONH_2)_2$. Converted by boiling dilute H_2SO_4 or HCl into the acid. (E. v. Meyer, *J. pr.* [2] 26, 358).

Properties.—Rows of prisms, or, from hot concentrated solution in water, globular aggregates. Begins to sublime at 100°. Readily soluble in alcohol and ether.

Salts.—$A''H(NH_4)$. Solutions of this salt give the following precipitates: Fe_2Cl_6, reddish-white; $AgNO_3$, white; $CuSO_4$, green; $Pb(OAc)_2$, on agitation, prisms crossing one another; $HgCl_2$, $CaCl_2$, $BaCl_2$ give no pps.—$A''Ag_2$.—$A''Cu$.—$A''Pb$, ½aq.

Amide.—(See above.)—Does not melt at 260°. Prisms with pyramidal ends (from water).

Adipic acid $C_4H_8(CO_2H)_2$ (*Hydro-pyro-cinchonic acid*) [194°]. Small white needles or glistening prisms; easily soluble in alcohol and ether, less in water. Is the chief product of reduction of pyrocinchonic acid $CO_2H.CMe{:}CMe.CO_2H$ or of the reduction of di-chloro-adipic acid $CO_2H.CClMe.CClMe.CO_2H$. By conversion into the anhydride and redissolving in water it is converted into the isomeric adipic acid melting at [240°].

Salts.—CaA'' 1½aq: very sparingly soluble white silky needles.—SrA'' 1½aq: sparingly soluble needles.—PbA'' 3aq: white crystalline pp.—$A''Cu$: green pp.

Anhydride.— $\left.\begin{matrix}CH(CH_3).CO\\ \dot{C}H(CH_3).CO\end{matrix}\right>O.$ [187°] (Otto a. Beckurts, *B.* 18, 838; Roser, *B.* 15, 2012; Leuckart, *B.* 18, 2344).

Constitution.—Probably identical with the above iso-adipic acid.

Adipic acid $(C_4H_8(CO_2H)_2)_n$ [210°]. Glistening plates, or prismatic needles. Formed by isomeric change from the preceding adipic acid [194°] by conversion into the anhydride and redissolving in water.

Salt.—Ag_2A'': sparingly soluble white crystalline pp. The acid does not give an anhydride on heating (Otto a. Beckurts, *B.* 18, 843).

Adipic acid $C_4H_8(CO_2H)_2$ [165°–167°]. *Di-methyl-succinic acid* (?)—From aceto-acetic ether by means of sodium, α-bromo-propionic ether, and MeI (Hardtmuth, *A.* 192, 142).

Salts.—PbA'': flocculent pp.—Ag_2A''.

Adipic acid $C_6H_{10}O_4$ [142°–143°].—From tropilene (*q. v.*) and HNO_3 (S.G. 1·285) (Ladenburg, *A.* 217, 140).

Salts.—Ag_2A''.—Ammonium salt forms triclinic crystals: $a:b:c = {·}8474:1:{·}5496$ $\alpha = 90°\,20'$. $\beta = 95°10'$. $\gamma = 100°\,56'$.

Constitution.—Probably identical with u-di-methyl-succinic acid (*q. v.*), $CO_2H.CMe_2.CH_2.CO_2H$.

Other isomerides of adipic acid are described as METHYL-ETHYL-MALONIC, PROPYL-MALONIC, ISO-PROPYL-MALONIC, DI-METHYL-SUCCINIC, ETHYL-SUCCINIC, and METHYL-GLUTARIC ACIDS.

Adipic (?) aldehyde $C_6H_{10}O_2$.—Formed by treating acetic aldehyde with zinc-turnings at 100° $3C_2H_4O - H_2O = C_6H_{10}O_2$. Smells like wild mint, and appears to be decomposed by prolonged distillation, with formation of H_2O and higher condensation products. Unites with alkaline bisulphites, forming crystalline compounds (Riban, *C. R.* 75, 98). H. W.

ADIPOCERE.—A fatty substance produced in the decomposition of animal substances in moist ground; first found by Fourcroy in the *Cimetière des Innocens* at Paris. Consists of palmitic, stearic, and oleic acids (Gregory, *A.* 61, 362; Wetherill, *J.* 1855, 517). According to Ebert (*B.* 8, 775) it consists essentially of palmitic acid, together with margaric and oxymargaric acids, $C_{17}H_{34}O_2$ and $C_{17}H_{34}O_3$. H. W.

ADIPOMALIC ACID $C_6H_{10}O_5$, is formed by boiling bromadipic acid with potash, as a viscid mass which becomes crystalline.—$PbC_6H_8O_5 5H_2O$. White precipitate which dissolves in hot solution of lead acetate and separates therefrom in nacreous scales. Gives off $2H_2O$ at a moderate heat (Gal a. Gay-Lussac, *C. R.* 70, 1175). H. W.

Para-adipo-malic acid *v. di*-ACRYLIC ACID.

ADIPOTARTARIC ACID $C_6H_{10}O_6$. Formed by heating pulverulent dibromadipic acid with water at 150°. Moderately soluble in alcohol and ether. Much more soluble in hot than in cold water, and separates in monoclinic laminæ. Optically inactive. Solution agitated with KOH yields a crystalline pp. resembling cream of tartar (Gal a. Gay-Lussac). H. W.

ADONIDIN. A glucoside in *Adonis vernalis*, resembling digitalin in physiological action (Cervello, *Ph.* [3] 13, 129; Mordagne, *Ph.* [3] 16, 145).

ADONINIDINE. A poisonous substance in *Adonis cupaniana* (Cervello, *G.* 14, 493).

ÆSCIGENIN $C_{12}H_{20}O_2$. Formed, together with glucose, by passing HCl-gas into a boiling alcoholic solution of telæscin (*infra*)

$$C_{18}H_{30}O_7 + H_2O = C_{12}H_{20}O_2 + C_6H_{12}O_6$$

Indistinctly crystalline powder, insoluble in water, soluble in alcohol. Strong sulphuric acid, in presence of sugar, dissolves it with blood-red colour. Acetyl chloride converts it into a diacetate (Rochleder, *J.* 1867, 751). H. W.

ÆSCINIC ACID $C_{24}H_{40}O_2$. Occurs in small quantity in the cotyledons of ripe horse-chestnut seeds. Formed, together with propionic acid, by boiling argyræscin with potash-lye:

$$C_{27}H_{42}O_{12} + 2KOH = KC_{24}H_{39}O_{12} + KC_3H_5O_2,$$

and together with butyric acid by similar treatment of aphrodæscin:

$$C_{52}H_{82}O_{23} + 3KOH = 2KC_{24}H_{39}O_{12} + KC_4H_7O_2.$$

Gelatinous mass, becoming partially crystalline.

Resolved by hydrochloric acid into glucose and telæscin:

$$C_{24}H_{40}O_{12} + H_2O = C_6H_{12}O_6 + C_{18}H_{30}O_7.$$

The acid potassium salt $KC_{24}H_{39}O_{12},C_{24}H_{40}O_{12}$, forms silky needles, sl. sol. water (Rochleder). H. W.

ÆSCIORCEÏN $C_9H_7NO_5$. A substance resembling orceïn, formed by the action of ammonia-vapour on moist paraæsculetin:

$$C_9H_8O_4 + NH_3 + O = H_2O + C_9H_7NO_5$$

(Rochleder, *J.* 1867, 753). H. W.

ÆSCIORCIN $C_9H_8O_4$, is formed by the action of sodium amalgam on æsculetin. Dissolves in alkalis with green colour quickly changing to red. Converted by ammonia into æsciorceïn (Rochleder, ibid. 751). H. W.

ÆSCIOXALIC ACID $C_7H_6O_6,H_2O$. Produced, together with formic and oxalic acids, sometimes also protocatechuic acid, by boiling æsculetin with very strong potash lye. More easily obtained pure by boiling æsculetin for several hours with baryta water in an atmosphere of hydrogen. Very minutely crystalline mass. Gives with ferric chloride a red-brown colour, changing to purple-violet on addition of sodium carbonate; with ferrous sulphate and a small quantity of sodium carbonate, a deep blue colour (Rochleder, *J.* 1867, 752). H. W.

ÆSCULETIC ACID $C_9H_8O_5$, *i.e.* $C_6H_2(OH)_3CH{:}CH.CO_2H$. Formed by boiling æsculetin with baryta (Rochleder, *J. pr.* 69, 211).

Salts.—BaA'_2.—$5PbC_9H_6O_5,C_9H_8O_5$. Acids which contain the group $CH{:}CH.CO_2H$, such as fumaric and maleïc acids and the coumaric acids, are usually capable of existing in two forms, one of which can be easily transformed into the other. Æsculetic acid and its methyl derivatives are at present known in one form only, but tri-ethyl æsculetic acid and its ether have been obtained in two forms, which are described below as derivatives of (α) and (β) æsculetic acid.

Tri-methyl derivative $C_6H_2(OMe)_3.C_2H_2.CO_2H$ [168°]. Needles. Soluble in alcohol, ether, benzene, and hot water, sparingly in cold water. Formed by the action of alcoholic KOH on the following body. Its neutralised solution gives pps. with $AgNO_3$, $CuSO_4$, $ZnSO_4$, and $Pb(OAc)_2$.

Methyl ether $C_6H_2(OMe)_3.C_2H_2.CO_2Me$ [109°]. Prisms. Distils undecomposed at a very high temperature. Soluble in alcohol, ether, and benzene, insoluble in water. Formed by evaporating dimethylæsculetin (1 mol.) with a solution of NaOH (2 mols.) nearly to dryness and digesting the residue dissolved in methyl alcohol with methyl iodide (Tiemann a. Will, *B.* 15, 2082).

(α)-ÆSCULETIC ACID $C_6H_2(OH)_3.CH{:}CH.CO_2H$

Tri-ethyl-derivative $C_6H_2(OEt)_3.C_2H_2.CO_2H$ [103°]. Prepared by saponification of its ether. Changes when heated to its boiling point or boiled with strong HCl into the (β)-isomeride.

On reduction with sodium-amalgam the tri-ethyl-derivatives of both (α)- and (β)- æsculetic acid give the same tri-ethoxy-phenyl-propionic acid, $C_6H_2(OEt)_3CH_2CH_2CO_2Et$, and with alkaline $KMnO_4$ the same tri-ethoxy-benzoic aldehyde, $C_6H_2(OEt)_3CHO$.

Ethyl-Ether $C_6H_2(OEt)_3.C_2H_2.CO_2Et$ [51°], thick yellow prisms, very soluble in alcohol, ether, and benzene, insoluble in water; prepared by heating di-ethyl-æsculetin with sodium ethylate and ethyl-iodide at 100°, avoiding an excess of ethyl-iodide and longer heating than four hours; on heating to its boiling point (above 230°) it changes into the (β)-isomeride (Will, *B.* 16, 2110).

(β)-ÆSCULETIC ACID $C_6H_2(OH)_3.CH{:}CH.CO_2H$

Tri-ethyl-derivative $C_6H_2(OEt)_3.C_2H_2.CO_2H$ [144°], colourless silvery crystals, easily soluble in alcohol, ether, and benzene, nearly insoluble in water; formed by saponification of its ether, or by heating the (α)-isomer to its boiling point.

Ethyl-Ether $C_6H_2(OEt)_3.C_2H_2.CO_2Et$ [75°], glistening tables, easily soluble in alcohol, ether and benzene, insoluble in water, distils undecomposed above 360°; prepared by heating di-ethyl-æsculetin with ethyl iodide and sodium ethylate at 100° for 8 hours; it is also formed by heating the (α)-isomeric ether to its boiling point (Will, *B.* 16, 2108).

ÆSCULETIN

$$C_9H_6O_4,\ i.e.\ C_6H_2(OH)_2\begin{cases}CH{:}CH\\ \quad\ \ |\\ O\ .\ CO\end{cases}$$

Occurs in very small quantity in horse-chestnut bark. Formed by the action of dilute acids or of emulsin on æsculin (Rochleder, *J.* 1863, 589).

Preparation.—A solution of æsculin in warm strong hydrochloric acid is boiled till it solidifies to a crystalline pulp; this after washing with water is dissolved in warm alcohol; the solution precipitated with lead acetate; the precipitate of lead-æsculetin is washed with alcohol and afterwards with boiling water, then suspended in boiling water and decomposed by hydrogen sulphide; the liquid is filtered at boiling heat; and the æsculetin which separates on cooling is recrystallised (Zwenger, *A.* 90, 63).

Properties.—Very thin shining needles or scales consisting of $C_9H_6O_4,H_2O$; bitter, slightly soluble in cold, more soluble in warm, water and alcohol, nearly insoluble in ether. Aqueous solution exhibits a very faint blue fluorescence, considerably exalted, however, by addition of a small quantity of ammonium carbonate. Deep green coloration with ferric chloride; yellow precipitate with lead acetate. Æsculetin dissolves in hydrochloric acid; and is oxidised by nitric acid to oxalic acid. By boiling with very strong potash-lye, it is converted into formic, oxalic, protocatechuic, and æscioxalic acids; by sodium amalgam into æsciorcinol.

A hydrate $C_9H_6O_4,\frac{1}{2}H_2O$, isomeric with daphnetin, occurs in horse-chestnut bark in larger quantity than anhydrous æsculetin. It is less soluble in water than the latter, and crystallises therefrom in small granules. Sublimes at 203°, and melts above 250°, converted into æsculetin by heating at 200° in CO_2-stream, also when crystallised from hot hydrochloric acid or from absolute alcohol mixed with strong hydrochloric acid (Rochleder, *J.* 1863, 588).

Æsculetin unites with MgO (Schiff, *B.* 13, 1951), and with solution of lead acetate forms a lemon-yellow precipitate having the composition $PbC_9H_4O_4$ (Zwenger, *A.* 90, 63).

Diacetylæsculetin $C_{13}H_{10}O_6$ *i.e.* $C_9H_4Ac_2O_4$ [134°] formed by treating æsculetin with acetic anhydride and sodium acetate. Crystallises from alcohol in prisms; from water in needles; dissolves in alcohol and ether; is not coloured by ferric chloride; is easily saponified by heating with strong sulphuric acid at 30° to 40° (Nachbauer, *A.* 107, 248).

Bromoæsculetins.—$C_9H_4Br_2O_4$, formed by treating dibromæsculin with strong sulphuric acid, crystallises from alcohol in yellowish needles melting at 233°, slightly soluble in

water.—$C_9H_4Br_2O_4$, formed by adding bromine to a hot solution of æsculetin in glacial acetic acid, crystallises from alcohol in long yellow needles, melting with decomposition at 240° (Liebermann a. Knietsch, *B.* 13, 1591).

Di-acetyl-di-bromo-æsculetin $C_{13}H_8Br_2O_6$ *i.e.* $C_9H_2Ac_2Br_2O_4$ [177°]. Formed by acetylation of di-brom-æsculetin crystallises from alcohol in slender needles.

Di-acetyl-tri-bromo-æsculetin $C_{13}H_7Br_3O_6$ *i.e.* $C_9HAc_2Br_3O_4$, formed by acetylation of tri-bromæsculetin, or by bromination of diacetylæsculetin, crystallises in long very thin needles, melting, with decomposition at 180°–182°; insoluble in water (L. and K.; Liebermann a. Mastbaum, *B.* 14, 475).

Methyl-æsculetin $C_{10}H_8O_4$ *i. e.* $C_9H_4O_2(OH)(OMe)$ [184°] is formed by heating æsculetin (6 pts.) with methyl iodide (15 pts.) and KOH (4 pts.) dissolved in a small quantity of methyl alcohol till the liquid becomes neutral. On treating the product, after the greater part of the methyl alcohol has been given off, with water and hydrochloric acid, methylæsculetin crystallises out, while dimethylæsculetin remains in solution.

Shining needles. Soluble in cold dilute alkalis and in ammonia, and precipitated therefrom by acids. Decomposed by boiling aqueous alkalis like æsculetin. Insoluble in cold, but soluble in hot water; easily soluble in alcohol, ether and benzene, insoluble in light petroleum (Tiemann a. Will, *B.* 15, 2075).

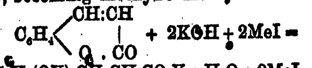
Dimethylæsculetin, $C_{11}H_{10}O_4$ *i. e.* $C_9H_4O_2(OMe)_2$ [144°], is deposited from the mother-liquor of the preceding compound on addition of ammonia. Shining needles. Easily soluble in alcohol, ether, and benzene, nearly insoluble in light petroleum; insoluble in cold, soluble in hot, water. Dissolved by H_2SO_4 and precipitated by water. H. W.

Ethyl-æsculetin $C_9H_4O_2(OH)(OEt)$ [143°], colourless crystals, soluble in alcohol, ether, benzene, alkalis, and hot water, insoluble in cold water.

Di-ethyl-æsculetin $C_9H_4O_2(OEt)_2$ [109°], colourless silvery plates, soluble in alcohol, ether, and benzene, sparingly in hot water, insoluble in cold water and cold aqueous alkalis (Will, *B.* 16, 2106).

Constitution.—Æsculetin contains two hydroxyls, for it forms a di-acetyl derivative. The formation of protocatechuic and of tri-ethoxy-propionic acids and of tri-ethoxy-benzoic aldehyde from æsculetin and tri-ethyl-æsculetic acids respectively show them to be aromatic bodies. If we compare the formulæ for coumarin $C_9H_6O_2$, umbelliferon, $C_9H_6O_3$ and æsculetin, $C_9H_6O_4$, we see that the two latter may be regarded as oxy- and di-oxy-coumarin. That umbelliferon is oxy-coumarin has been proved by synthesis (Tiemann a. Reimer, *B.* 12, 993). All three bodies are fluorescent in alkaline solution, but methyl-umbelliferon, $C_9H_5O_2(OMe)$ and methyl-æsculetin fluoresce more strongly than umbelliferon and æsculetin respectively, while di-methyl-æsculetin, $C_9H_4O_2(OMe)_2$, fluoresces most strongly of all.

When coumarin (1 mol.) is evaporated with NaOH (2 mols.) and the residue digested with MeOH and MeI, it takes up the elements of Me_2O, becoming methylic methyl-*o*-coumarate;



$$C_6H_4\left\langle\begin{matrix}CH:CH\\ \quad | \\ O\,.\,CO\end{matrix}\right. + 2KOH + 2MeI =$$

$$C_6H_4(OK).CH:CH.CO_2K + H_2O + 2MeI =$$
$$C_6H_4(OMe).CH:CH.CO_2Me + H_2O + 2KI.$$

But two isomerides may be got in this way, one, (α), when excess of MeI is avoided and the digestion is for 3 hours at 100°, the other (β) by digesting for a longer time at 150° (W. H. Perkin, *C. J.* 31, 417; 39, 409). Precisely the same reaction occurs when di-ethyl-æsculetin is digested with NaOEt and EtI, the two isomeric ethers, $C_6H_4(OEt)_3.CH:CH.CO_2Et$, being formed, the (α) compound when excess of EtI is avoided and the heating kept up for only four hours, the (β) compound by more prolonged heating. In both cases the (α) compounds are changed by distillation into the (β) compounds. These reactions indicate analogous structure.

It is however, remarkable that di-methyl-æsculetin does not form a dibromide as coumarin does.

Paraæsculetin.—$C_9H_6O_4$ (?).—Obtained by treating æsculetin with aqueous $NaHSO_3$, at boiling heat, then adding rather dilute sulphuric acid and afterwards alcohol, whereby Na_2SO_4 is first thrown down, and then the compound $C_9H_6O_4,NaHSO_3$, which when decomposed by sulphuric acid yields hydrated paraæsculetin $C_9H_6O_4,2\frac{1}{2}H_2O$ in indistinct crystals easily soluble in water, sparingly in ether, more freely in alcohol, less easily in wood-spirit, nearly insoluble in acetone and chloroform, soluble in glacial acetic acid. Paraæsculetin exerts a strong reducing action in alkaline solution, throws down metallic copper from Fehling's solution at 50°-70°, and reduces indigo at ordinary temperature. Not attacked by acetic anhydride. Exposed in the moist state to ammonia-vapour, it quickly turns red, then dingy-violet, and changes after a few minutes to a sky-blue liquid, which when left over sulphuric acid gives off ammonia, and again turns red, from formation of æsciorceïn (p. 65). Converted by heating with aniline into æsculetanilide (Rochleder, *J.* 1863, 589; 1867, 752).

$C_9H_6O_4,NaHSO_3,\frac{1}{2}H_2O$ forms small needles. According to Liebermann a. Knietsch (*J.* 1880, 1028), the true formula of this compound is $C_9H_8O_4,NaHSO_3$; it probably therefore contains a hydro-æsculetin. H. W.

ÆSCULIN $C_{15}H_{16}O_9$ [204·5°–205°] (H. Schiff, *B.* 14, 302).—Occurs in the bark of the horsechestnut (*Æsculus Hippocastanum*) especially in March before the buds open (Minor, *B. J.* 12, 274; Jonas, *A.* 15, 266).

Preparation.—1. Horsechestnut bark is exhausted by boiling with water; the extract is precipitated with lead acetate, and the filtrate, freed from lead by hydrogen sulphide, is evaporated to a syrup. The æsculin then crystallises out after a few days, and may be purified by washing with water, and crystallising, first from weak spirit (40 p.c.), then from boiling water (Rochleder a. Schwarz, *A.* 87, 186).—2. The bark is exhausted with weak aqueous ammonia; the solution evaporated to dryness; the residue, mixed with alumina and exhausted with alcohol of 95 p.c.; and the æsculin which crystallises from the alcohol is agitated with water and

ether, and finally washed with benzene (Fairthorne, *C. N.* 26, 4).

Properties.—Small prisms, composed of $C_{15}H_{16}O_9,2H_2O$. Bitter, sparingly soluble in cold, easily in boiling water, the solution coagulating on cooling. 1 pt. dissolves in 24 pts. boiling alcohol. Very slightly soluble in absolute ether, soluble in glacial acetic acid and ethyl acetate (Trommsdorff, *A.* 14, 200). The aqueous solution is slightly acid, and exhibits a blue fluorescence which disappears on addition of acids, but is restored by alkalis. Dissolves in alkalis more readily than in water.

Reactions.—1. Æsculin is resolved at 230° into glucosan and æsculetin: $C_{15}H_{16}O_9 = C_6H_{10}O_5 + C_9H_6O_4$ (Schiff); by digestion with dilute mineral acids or by treatment with emulsin, into glucose and æsculetin (Rochleder a. Schwarz, *A*, 88, 356); by boiling with baryta-water into glucose and æsculetic acid (Rochleder *J. pr.* 69, 211).—2. Converted by sodium-amalgam into hydræsculin (Rochleder).—3. Agitated with a small quantity of nitric acid, it yields a yellow solution which assumes a deep blood-red colour on addition of ammonia, this reaction affords a delicate test for æsculin (Sonnenschein).—3. Conc. H_2SO_4 (4 drops) followed by NaOClAq gives a violet colour (Raby, *J. Ph.* [5] 9, 402).

Æsculin forms with magnesia, the compound $2C_{15}H_{16}O_9Mg(OH)_2$, which is yellow and dissolves readily in water (Schiff, *B.* 13, 1952).

Pentacetylæsculin

$C_{25}H_{26}O_{14}$ *i.e.* $C_{15}H_{11}Ac_5O_9$.

Formed by heating æsculin with acetic oxide crystallises from alcohol in small needles melting at 130° (Schiff, *A.* 161, 73; *B.* 13, 1952).

Di-bromo-æsculin $C_{15}H_{14}Br_2O_9$.

Is obtained by gradually adding bromine in calculated quantity to a solution of æsculin in glacial acetic acid. Crystallises from glacial acetic acid in small needles; melts and decomposes at 193°-105°. Sparingly soluble in alcohol, still less in all other solvents (Liebermann a. Knietsch, *B.* 13, 1594).

Pentacetyl-dibromo-æsculin

$C_{25}H_{24}Br_2O_{14}$ *i.e.* $C_{15}H_9Br_2Ac_5O_9$, prepared in like manner from dibromæsculin, forms slender needles, melting at 203°-206°, converted by strong sulphuric acid into dibromæsculetin.

Pentabenzoylæsculin $C_{50}H_{36}O_{14}$ *i.e.* $C_{15}H_{11}Bz_5O_9$, forms nodular groups of crystals sparingly soluble in ether, freely in hot alcohol (Schiff).

Trianilæsculin

$C_{33}H_{31}N_3O_6$ *i.e.* $C_{15}H_{16}(NC_6H_5)_3O_6$, from æsculin and aniline by prolonged heating at 200°. Amorphous brown powder, soluble with red colour in alcohol (Schiff, *B.* 14, 472). H. W.

ÆTHAL *v.* CETYL ALCOHOL.

ÆTHOKIRRIN. The yellow colouring matter of the flowers of *Antirrhinum Linaria.* H. W.

AFFINITY.—Chemical affinity is that property of bodies in virtue of which, when brought into contact, they react on each other, forming new bodies. It can be called a force, in so far as by its action energy is produced, namely, heat, light, electrical or mechanical energy. And, *vice versâ*, energy must be employed to reverse the action of chemical affinity, and to decompose the combined substances.

Nothing is known as yet about the nature of chemical affinity, nor has a satisfactory hypothesis been suggested concerning it. The oldest conceptions concerning the reasons why substances react on each other reach back to Greek philosophy; nothing has survived of them except the name affinity, which preserves the notion that those substances which are of the same origin or of the same kind, and which therefore are as it were related to each other, possess the power of mutual reaction. It is now known that the contrary of this is more correct. Moreover, the reason of the greater or smaller facility with which substances react chemically was conceived to be somewhat similar to human qualities—sympathy and antipathy. These conceptions held sway as long as the philosophy of Aristotle reigned. The breach with these ideas, which was brought about by Galileo's mechanics, introduced mechanical ideas into chemistry also. The ultimate particles of substances were imagined as furnished with points, edges, and hooks, by the aid of which were brought about their decompositions and combinations. Sir Isaac Newton's discovery of the general mutual action of masses introduced a new phase into the conception of nature. The idea of an attractive action between one small particle and another at a distance was introduced by Newton himself into chemistry, in order to explain the mutual reactions of bodies. He did not, however, consider the cause of chemical actions as identical with that of general gravitation, but as different from it, especially as regards the law concerning action at a distance.

Later investigators, Buffon, Bergmann, Berthollet, assumed, on the contrary, that both forces are of the same nature, and that only the circumstances under which chemical forces act—especially the close proximity of the reacting particles—cause an apparent difference.

An influence similar to that due to Newton's astronomical discovery was exerted at the beginning of this century by a physical discovery, that of the electric current. The great chemical activity of the current was soon noticed. By its help Davy decomposed the alkalis and earths; and Berzelius made use of the phenomena of electrical decomposition for the foundation of a theory concerning chemical compounds, which rested on the supposition that chemical attraction was nothing but the attraction of the opposite electricities concentrated on the smallest parts of substances.

The electro-chemical theory of Berzelius was the first chemical theory which was based on facts. Owing to this it obtained great importance. Taking into account the needs of the time, Berzelius developed his theory only with a view towards classification; but it did not contribute anything towards the investigation of the nature of chemical affinity.

The last great change in the views concerning affinity took place in the middle of this century, and was brought about by Mayer's and Joule's discovery of the equivalence of 'forces,' or more strictly, of 'the actions of forces.' It was recognised that chemical affinity was to be classed with mechanical, electrical, and thermal energy, in so far as it is convertible into any of these, and can be produced from each of them

When this was known, the need to trace back the mode of action of the forces of affinity to other known actions of forces ceased to exist, as a great many inferences could be drawn from this experimental fact, and a special hypothesis did not seem called for.

Two different views have been held concerning the way in which chemical forces act, and each of these has still its followers at the present day. First it was imagined that the force acting between two different kinds of matter is similar to that acting between two masses; it brings the ultimate particles nearer together, and, if under the given circumstances this is possible, it produces combination. It would be difficult to entertain different ideas concerning the simple process of combination. The task becomes far more difficult when it is a question of simultaneous decomposition and combination. Very often a substance acts on another which is a compound without combining with it as a whole, but only combining with one of its constituent parts, and expelling the other from the original compound. The hypothesis indicated above refers these facts to the opposite action of two forces, similar to two mechanical forces opposite in direction and unequal in magnitude, which produce motion in the direction of the greater. It was imagined that the stronger chemical affinity overcame the weaker, and produced chemical action in its own direction.

It was in accordance with this conception that 'tables of affinity' were compiled which were to give an account of the force of chemical affinity according to its order. Such tables were first published in 1718 by H. Geoffroy. They contained, under the head of any one substance, a series of others, all of which could enter into chemical combination with the specified body. They were so arranged that the preceding body would always replace all the following bodies from their combinations with the one at the head of the list. Such tables of affinity, which were very popular during the last century, culminated in the works of Bergmann, who collected the ideas indicated above in a theory of affinity. Bergmann recognised that substances can react differently according to circumstances, and therefore he gave two tables for each substance, one for the action in aqueous solution—'in the wet way'; the other for the action at the temperature of fusion—'in the dry way.' Beyond this he kept to the idea that chemical affinity always acts exclusively in one direction, so that under all circumstances a smaller affinity is overcome by a greater.

To Claude Louis Berthollet is due the great merit of having shown this view to be too narrow. According to him, besides 'the intensity of the forces,' the 'mass' of the reacting substances is of importance, in so far as under the same conditions the action is the greater the more of the reacting substances there is present. '*Toute substance qui tend à entrer en combinaison, agit en raison de son affinité et de sa quantité*' (*Statique chimique*, p. 2). This is the concise expression of the new idea which Berthollet introduced into the theory of affinity. But it was reserved for a much later time to develop this idea scientifically, since one of the chief applications which its author made of it—namely, the inference that compounds according to fixed proportions do not exist, but only such as vary in composition within fixed limits—was proved to be false. The proof of this error which was given by Proust, Berthollet's compatriot, brought also the correct foundation into discredit. To this must be added, that in the discoveries of Richter, Dalton, and Berzelius, the science found such important and productive tasks that there was no inducement to investigate what of truth was left in the partially refuted hypothesis of Berthollet. The idea of 'influence of mass' is the first, but not the only, conception which the science owes to Berthollet. This chemist further recognised the decided influence of the physical states of the reacting bodies on the final results of the actions of affinity. He taught that the simple action, according to the measure of affinity and mass, holds only for homogeneous mixtures, but holds no longer when by the appearance of certain substances in a different state of aggregation the chemical equilibrium is disturbed. The influence of '*cohésion*' and '*élasticité*,' on the results of chemical actions, were explained by him perfectly clearly; how first equilibrium is established in the usual manner, but is afterwards disturbed by one of the substances separating out in a different state of aggregation; in consequence of this, a fresh quantity of this substance is formed, and is again separated, and thus the process repeats itself until the substance in question—gaseous or solid—has been entirely, or almost entirely, removed from the changing system. A chemical reaction carried to completion, which had been taken by Bergmann to be the normal case, appears, according to Berthollet, as the exceptional case, and occurs only because of differences in the states of aggregation of the reacting substances.

The decision between these two fundamentally different views has not yet been completely made. Even now, Bergmann's theory is propounded by some investigators, though in a somewhat modified form. In place of the greater or smaller affinity, the greater or smaller production of heat is considered by these investigators as decisive of the course of a chemical action; the fundamental idea, however, the 'exclusiveness' of the reaction, is presupposed by them also. In order to explain those partial reactions in the opposite direction, which certainly occur, those who maintain the theory of Bergmann are obliged to admit that such partial reactions are possible under certain conditions, notably under the influence of heat. These authorities are therefore under the necessity of proving the presence of such special conditions in all those cases wherein we deal with incomplete reactions. Berthollet's theory, on the other hand, by making use of one and the same principle, embraces both kinds of chemical action, and teaches us to consider the one as the limiting case of the other. Apart from this logical advantage it has another; it allows us to apply definite laws, which can be stated in a mathematical form, to the action of affinity taken in conjunction with the action of mass. But this cannot be done by Bergmann's theory, whether in its old or in its new form.

Berthollet's views met with respect and appreciation from his contemporaries, but not with continuation and development; because chemistry began at this time to follow another path which had been opened up by Dalton and Berzelius. Thus it was possible for the fundamental fact of the influence of mass, the fact, namely, that chemical action decreases and increases with the relative quantities of the acting substances, to be denied; and it became necessary to prove this fact at length by many special cases before it could be regarded as a secure property of science. One of the first investigators to whom the merit of this proof is due was H. Rose (*P.* 82, 545), who showed that in the formation of many carbonates of the heavy metals, by precipitating aqueous solutions of the salts of these metals by sodium carbonate, the precipitates contained less carbonic acid and more metallic hydroxide the more water was present in the original solutions. It followed therefore that the water, according to its quantity, expelled the carbonic acid from its combination with the metal. Rose found further (*P.* 94, 481; 95, 96) that when barium sulphate was fused with an equivalent quantity of potassium carbonate it was only partially converted into carbonate. If the quantity of potassium carbonate was increased, appreciably more barium sulphate was decomposed, but only with a proportion of 6 to 7 equivalents did the decomposition become approximately complete.

Another case of the influence of mass was investigated by Bunsen (*A.* 85, 131). If to a mixture of carbonic oxide and hydrogen a quantity of oxygen is added, less than sufficient for the complete combustion of the two gases, a division of the oxygen between the two combustible gases take place. The proportion in which the oxygen combines with either gas depends on the relative masses of these gases. Bunsen's further result, that these proportions can be expressed by some small multiples of the atomic weights of the gases, has been recognised to be an error. Debus (*A.* 85, 103) proved in Bunsen's laboratory the fact of the influence of mass on the precipitation of mixed solutions of lime and baryta by insufficient quantities of carbonic acid. In 1865 Gladstone (*Tr.* 1855, 179; and *C. J.* 9, 54) proved the general truth of the influence of mass in various ways. His method consisted in using certain definite physical properties, especially colour, and the rotation of the plane of polarisation of a ray of light, from measurements of which to draw conclusions concerning the arrangement of compounds in a homogeneous solution. Thus, by comparing the colour of pure ferric sulphocyanide with the colour produced in mixed solutions of iron salts and potassium sulphocyanide, the same amount of iron being present in both solutions, he established the fact, that by the reaction of three equivalents of potassium sulphocyanide and one equivalent of an iron salt, only 13 per cent. of ferric sulphocyanide was formed, and that even in the presence of 375 equivalents of potassium sulphocyanide the whole of the iron had not been converted into sulphocyanide.

By this and similar methods Gladstone established the following laws:

1. When two or more binary compounds are mixed so that all resulting compounds have the power of reacting on each other, each electropositive element enters into combination with each electronegative element, and it does so according to fixed and constant proportions.

2. These proportions are independent of the manner in which the different elements are initially arranged. They are also not only the resultants of the various forces of attraction between the different substances, but depend also on the mass of each of these substances.

3. An alteration in the mass of one of the binary compounds produces a change in the quantity of each of the other binary compounds, and it does so in a ratio which progresses regularly. Sudden changes occur only when a substance can combine with another in more than one proportion.

4. The equilibrium of affinities is generally established after a very short time, but in some cases the elements attain their final condition only after hours.

5. The resulting effects are completely altered when precipitation, volatilisation, crystallisation, and similar phenomena, occur; in such cases the equilibrium which had been established at first is again disturbed by the removal of some of the chemically active substances.

Harcourt and Esson (*C. J.* [2] 5, 460) examined the reaction between hydrogen peroxide and hydriodic acid, and also that between potassium permanganate and oxalic and sulphuric acids. They concluded that 'when any substance is undergoing a chemical change, of which no condition varies except the diminution of the changing substance, the amount of change occurring at any moment is directly proportional to the quantity of the substance.'

The principle, first established by Steinheil (*A.* 48, 153), of determining the chemical composition of a homogeneous liquid by means of physical measurements, was put to practical use by Gladstone in various ways. His measurements might have served as a direct basis of a theory concerning the influence of mass, had such a theory existed. But even the extensive investigations of Berthollet and St. Giles on the etherification of acids and alcohols (*A. Ch.* 61, 65; 66, 68), by which the chemical influence of mass had been confirmed and the magnitude of this influence had been measured, did not give rise to the formulation of a mathematical theory of affinity.

Meanwhile a number of theoretical conceptions, some of old standing, were pointing in the same direction. As far back as 1851 Williamson (*A.* 77, 37; and *C. J.* 4, 110) in his fundamental researches on etherification, had propounded a theory concerning the course of chemical reactions, which explained, better than had been done before, the nature of the chemical influence of mass. According to him, substances which react on each other, when in contact or mixed together, are by no means in a state of neutral equilibrium, but rather in one involving a continuous exchange of constituents. The final result of the reaction depends on the direction in which this exchange of constituents can take place most easily and most frequently. The state of chemical equilibrium arrived at under any conditions is thus not a statical one, in which the forces balance each other and so no more produce any effect, but is rather a dynamical state, in which two opposite reactions occur continually to the same extent, so that the average state of the system remains the same.

Williamson's theory was accepted for the special case for which it had been propounded. Neither the author nor any of his contemporaries, however, made an application of it to the general explanation of chemical reactions. Meanwhile, hypotheses were developed on an entirely different basis, which agreed with this theory in a most remarkable manner. These are the views concerning the gaseous state, which, first propounded by D. Bernoulli, and afterwards, independently, by Herapath, Joule, Krönig, and Clausius, were developed by Clausius and Maxwell in a mathematically well-founded theory of the states of aggregation. According to this theory, bodies are made up of molecules, which are in a state of continual motion. In the case of gases this motion is rectilinear, until the molecules meet with some resistance, whereby they are caused to rebound according to the laws of collision of elastic bodies. The velocity of motion increases with the temperature, and is inversely proportional to the square root of the molecular weight of the gaseous body. Likewise, there is motion within the molecules, which motion is of the nature of oscillations, the intensity of which bears a constant ratio to the motion of the molecule as a whole. Moreover, at any specified temperature, the molecules of a homogeneous gas have not all the same velocity, but have different velocities varying from the mean value in such a manner that deviations from this value are the fewer the greater they are. In the case of liquids, the molecules have no longer the power of translational motion, but are compelled to fill a definite space owing to the forces which act between them. In other respects the statements made for gases hold good for liquids also, especially those referring to the differences of condition of the various molecules of a homogeneous substance at a constant temperature. The theory has been least developed for the case of solids; here it is to be assumed that the intermolecular forces assign to the various molecules very definite relative positions of equilibrium (*v.* AGGREGATION, STATES OF, p. 87).

The application of these ideas to chemical processes has been made by L. Pfaundler (*P.* 131, 55). It can easily be seen how they directly lead to conceptions which do not appreciably differ from those of Williamson. The molecular conceptions are, however, a decided improvement on those of Williamson, since, in the differences of the conditions of various molecules, they supply a reason for the continuous interchange of atoms which Williamson supposed to occur. When the velocity of motion exceeds a certain amount, there will always be present some molecules in which this velocity is so great that the connection between the atoms is loosened or destroyed. These molecules are then ready to interchange their constituent atoms, while other molecules, which have a smaller velocity, will not do so. This is the explanation for partial reactions. The same conceptions, when slightly modified, lend themselves to the explanation of the influence of mass and to that of reversible reactions.

At the same time as these hypotheses concerning the mechanism of chemical processes were developed, Guldberg and Waage (*Etudes sur les Affinités chimiques*, Christiania, 1867) laid the foundation for the exact development of the theory of affinity by establishing a mathematical law for the influence of mass. Their work marks an epoch in the history of affinity. It was they who first gave a possibility of determining numerically the intensity of chemical affinities, though at first only as relative magnitudes.

The law established by these two investigators states 'that chemical action is proportional to the active masses of each of the substances participating in the reaction.' By 'active mass' is understood that quantity of the substance participating in the reaction, measured in equivalents or in molecular weights, which is contained in unit volume of the system. This is the same idea as underlay the views of Berthollet; it is the same, only freed from the errors which were attached to it in his time and thrown into an exact mathematical form. Guldberg and Waage lay special stress on the fact that, when the action of several substances on each other is proportional to the active mass of each separately, the intensity of the reciprocal actions among the substances is measured by the product of these masses.

In their earlier paper Guldberg and Waage developed the equations for the chemical equilibrium of opposite reactions by putting the chemical *forces* as proportional to the product of the active masses. On the other hand, as proportional to these same forces they put the *velocities* of the reactions, *i.e.* the relation between the quantity of substance changed and the time necessary to effect the change. In their later papers it was found better to refer the considerations, not to the forces, but to the velocities of the reactions, since these are capable of exact definition, and to leave out of account altogether the somewhat vague idea of chemical forces. According to this conception, chemical equilibrium results when the velocities of the opposite reactions have become equal, *i.e.* when the quantity of substance undergoing a certain change is equal to the quantity formed by the reverse process. It is evident that this is the same theory as had been framed by Williamson, and developed by Pfaundler. The empirical law of the influence of mass thus receives a reasonable foundation in the molecular theory of matter. The effect is proportional to the active mass, because the number of molecules which can react is proportional to the mass. On these lines Van't Hoff (*B.* 10, 669) has deduced the law of the influence of mass. He retains exactly the form given to it by Guldberg and Waage; and in a later paper (*J. pr.* [2] 19, 69) these authors accepted this formal improvement.

In the following part I propose to give a short systematic review of chemical kinetics, or the doctrine of the course of chemical actions, and to deduce from it the conditions and equations of chemical equilibrium; further on, the theoretical conceptions thus gained will be used in the practical determination of the magnitudes of affinities. The theoretical part is based mainly on the paper of Guldberg and Waage mentioned above. A book recently published by Van't Hoff (*Etudes de Dynamique chimique*) is also of importance, and has been of great use to the author, though he by no means agrees with the whole of its contents.

Chemical Kinetics.—Let us suppose some substance to be undergoing chemical change. Then in any time, dt, some quantity, dx, will have been changed. We define the velocity of the chemical reaction, c, as the ratio of the quantity changed to the time taken for the change, and we therefore put $c=\frac{dx}{dt}$. The quantities of the reacting substances are in every case measured by formula-weights.

The quantity of substance changed will be dependent on many conditions. Among these we find such as are constant, or can be kept constant, during the whole process. Such are temperature, pressure, volume, &c. One condition, namely, the quantity of substance undergoing change, necessarily varies during the process, and we have to find an expression for the velocity of the change as a function of this quantity. This may be done by putting

$$c=\frac{dx}{dt}=k\,f\;(x_2x_1),$$

where the constant factor k represents the constant conditions, and $f\,(x_1x_2)$ the conditions varying with the quantities $x_1, x_2. \;.\;.\;.$ Concerning the form of the function $f\,(x_1x_2)$ information has been sought and found in various ways. All the results arrived at are concordant, and show the function to be one of direct proportion. This result has been arrived at empirically, and also theoretically as a deduction from various assumptions. Guldberg and Waage did the first; Horstmann, and others after him, showed that for certain cases, especially for gaseous compounds, the law of direct proportionality between chemical action and mass follows as a necessary consequence from the second law of thermodynamics. Gibbs has made this result perfectly general. The kinetical theory of the constitution of matter leads to the same result, by considering the probabilities for the occurrence of those arrangements of particles which make chemical change possible.

Before, however, the proof for the law of direct proportion between chemical action and mass can be attempted we must distinguish between the various types of chemical reactions. As a rule, chemical action does not take place in the presence of one substance only, but more than one is needed to bring about the final result. Since the final result is proportional to the mass of each separately, we have quite generally

$$\frac{dx}{dt}=k,\,x_1,\,x_2,\,x_3,\,x_4,\,.\;.\;.\;x_n$$

where $x_1, x_2; x_3, \ldots x_n$ are the quantities of the various substances, and x the quantity of substance formed by their reaction. All these quantities are measured according to the ratios of the molecular weights of the various substances.

The simplest case is that in which one substance only undergoes change during the reaction, or that in which the change of only one substance has to be taken into account. The first case occurs when, for example, a substance is decomposed, or when it undergoes a molecular transformation; the second occurs when the other substances participating in the reaction are present in such quantities that the diminution of them occasioned by the chemical change is not appreciable. Since, then, the factors $x_2, x_3, \ldots x$ disappear or become constant, we have

$$c=\frac{dx}{dt}=k\,x_1.$$

The velocity of the reaction at any instant is proportional to that quantity of substance undergoing change which is still within the sphere of action.

This equation was first established by Wilhelmi (*P.* 81, 413) in 1850 for the inversion of cane-sugar. Since that time it has been confirmed in many ways. In order to compare it with the empirical results it must be integrated. If we put the quantity of substance present at the beginning of the change $=a$, then, after any time t, a quantity x will be decomposed, and, since we are dealing with molecular units, x will at the same time represent the quantity of the product of decomposition formed. The quantity x_1 of substance present at the time t is $(a-x)$, and we have therefore

$$\frac{dx}{dt}=k\;(a-x) \qquad \textbf{(1)}$$

$$\frac{dx}{a-x}=k.dt$$

$$-\log\,(a-x)=k.t+\text{constant},$$

where *log* represents the natural logarithm. In order to determine the constant of integration, a definite pair of values for x and t must be taken. We put both simultaneously equal to zero, *i.e.* we begin the time from the instant when the decomposition begins, and thence we get

$$-\log a=\text{constant, and}$$

$$\log a-\log\,(a-x)=\log\frac{a}{a-x}=kt.$$

In order to pass from the natural to the common logarithms we have only to multiply the constant k by its modulus.

Some series of experiments illustrative of this equation will now be given. The first of these refers to a simple decomposition, the change of dibromosuccinic acid into dibromomaleic acid and hydrobromic acid,

$$C_2H_2Br_2(COOH)_2=C_2HBr(COOH)_2+HBr,$$

a change which occurs in aqueous solution at 100°. This reaction has been studied by Van't Hoff (*Etudes de Dynamique chimique*, p. 13). The progress of the decomposition can be traced by titrating with standard alkali. The amount of alkali required for neutralisation before the action began was 10·25 (arbitrary units), and when the change was finished the amount of alkali was 15·32. The excess of alkali used, over 10·21, at any stage of the change is put as equal to x. For a we have 5·11, since two equivalents of dibromosuccinic acid give one equivalent of hydrobromic acid. Van't Hoff's results are presented in the table given on next page. The constancy of the value of k, as shown in the last column, furnishes a proof of the truth of the equation used.

A second series of experiments dealing with the inversion of cane-sugar by means of sulphuric acid is taken from the experiments of W. Ostwald (*J. pr.* 29, 394). The action is one of

t (minutes)	units alkali	x	$\log\frac{a}{a-x}$	k
0	10·21	0·00	—	—
2	10·53	0·32	0·0281	0·0141
4	10·79	0·58	0·0524	0·0131
6	11·05	0·84	0·0776	0·0129
8	11·25	1·04	0·0988	0·0124
10	11·55	1·34	0·1320	0·0132
13	11·94	1·73	0·1795	0·0138
16	12·29	2·08	0·2269	0·0142
19	12·53	2·31	0·2612	0·0138
22	12·84	2·63	0·3116	0·0143
26	13·03	2·82	0·3487	0·0134
30	13·30	3·09	0·4027	0·0135
34	13·57	3·36	0·4647	0·0137
39	13·71	3·50	0·5009	0·0129

52	14·32	4·11	0·7077	0·0137
60	14·52	4·31	0·8011	0·0135
71	14·69	4·48	0·9066	0·0128
90	15·03	4·82	1·2141	0·0138

the type called catalytic, *i.e.* the substance which brings about the change (in this case sulphuric acid) does not itself undergo any change. The sugar, by taking up water, is changed into dextrose and lævulose. The rotatory power changes in the same proportion as the decomposition proceeds; the course of the change can therefore be traced by means of the polariscope. The original solution rotated 25°04′; when completely inverted it rotated −8°15′, so that the total angle passed through was 33°19′; this number is at the same time the measure of the total amount of sugar, and must therefore be put $=a$. For x we have the difference $25°01'-w$, where w is the angle of rotation produced by the solution undergoing change at time t.

t (minutes)	w	x	$\log\frac{a}{a-x}$	k
58	20°20	4·84	0·0684	0·0001180
114	16°28	8·76	0·1331	1163
197	11°34	13·70	0·2315	1175
263	8°30	16·74	0·3052	1161
394	3°35	21·69	0·4602	1169
585	−1°39	26·43	0·6909	1182

Similar experiments have been made for many other cases and have given like results. For non-reversible chemical reactions, which depend on the quantity of a single substance only, the above formula holds good quite generally; it can however be proved only in the case of reactions which are sufficiently slow to allow of measurement.

A second main division of chemical processes is formed by those which involve the presence of two different substances. In such cases the general equation (1) takes the form

$$\frac{dx}{dt}=k.x_1.x_2 \qquad (2)$$

Two cases have to be distinguished here; either the quantities of the reacting substances are equivalent with respect to the chemical change considered, or one of them is present in excess. Putting these quantities $=a$ and b, then either $a=b$ or $a>b$. In the first case we have to put $x_1=x_2=a-x$ and we get

$$\frac{dx}{dt}=k(a-x)^2 \qquad (3)$$

and integrating

$$\frac{x}{a-x}=a.k.t \qquad (4)$$

where the constant of integration is determined on the same suppositions as before.

Decompositions of this type have often been investigated experimentally. The example given here is a series of experiments by Ostwald (*J. pr.* 27, 1), on the decomposition of acetamide by acids, especially by trichloracetic acid. This change takes place according to the equation:

$$CH_3.CONH_2 + CCl_3.CO_2H + H_2O = CCl_3.COONH_4 + CH_3.CO_2H.$$

The quantities both of acetamide and trichloracetic acid diminish, with production of inert ammonium trichloracetate, and acetic acid, which acid under the conditions of the experiment exerts little or no influence on the change. In the following table t stands for the time in minutes, x for the quantity of ammonium salt formed (or, what is the same thing, for the quantity of acetamide decomposed) measured in units such that the total quantity $a=26{\cdot}80$.

t	x	$\frac{x}{a-x}$	ak
15	3·13	0·132	0·0088
30	5·52	0·260	0·0087
45	7·61	0·397	0·0086
60	9·23	0·525	0·0088
90	12·01	0·811	0·0090
120	13·82	1·065	0·0089
150	15·51	1·375	0·0092
180	16·59	1·623	0·0090
240	18·33	2·169	0·0090

These results show that the quantity

$$ak=\frac{1}{t}\cdot\frac{x}{a-x}$$

is constant, as is required by theory.

A second series of experiments by R. Warder (*B.* 14, 1361) on the saponification of ethylic acetate gave similar results. Equivalent quantities of ethylic acetate and soda were mixed, and portions taken from time to time were neutralised by dilute acid. The quantities of acid used—these will be called s—give the quantities of the substances not yet decomposed. In each experiment the soda alone would have used 16·00 c.c. of acid; hence we have $a=16{\cdot}00$ and $x=16-s$, therefore also $a-x=s$

t (minutes)	s	x	$\frac{x}{a-x}$	ak
5	10·24	5·76	0·563	0·113
15	6·13	9·87	1·601	0·107
25	4·32	11·68	2·765	0·108
35	3·41	12·59	3·69	0·106
55	2·31	13·69	5·94	0·108
120	1·10	14·9	13·55	0·113

Again ak is sufficiently constant. When a and b are different, x_1 becomes $a-x$, and x_2 becomes $b-x$; then

$$\frac{dx}{dt}=k(a-x)(b-x)=k\{x^2-(a+b)x+ab\} \qquad (5)$$

the integral of this equation is

$$\log\frac{(b-x)a}{(a-x)b}=(a-b)kt. \qquad (6)$$

The validity of this equation has been proved by T. Flood (*P. M.* [5] 6, 371).

These two types of non-reversible chemical actions which have been just considered comprise all non-reversible actions which have been accurately studied. To be consistent, we must assume that in chemical reactions which involve more than two, say three, substances, an equation corresponding with those given ought to hold good. Thus when three substances are present in equivalent quantities, $\frac{dx}{dt}=k(a-x)^3$; and

$$\tfrac{1}{2}.\frac{2ax-x^2}{(a-x)^2}=a^2.kt. \qquad (7)$$

But no reaction has been observed with sufficient certainty the course of which proceeds according to this, or according to a higher, equation.

Moreover, a complication may arise from the simultaneous occurrence of several reactions. For such a case the principle of the 'coexistence of reactions' is important; this principle states that every reaction proceeds as if it alone took place. This principle is of paramount importance; it forms the connecting link between the simple reactions, and those of so-called chemical equilibrium. For the mathematical expression of the coexistence of reactions, when one and the same substance is affected by the various changes, we have the following,

$$\frac{dx}{dt}=k.x_1x_2\ldots + k'x'_1x'_2\ldots + k''x_1''x_2''\ldots$$

If, however, the coexistent reactions take place among different groups, which are themselves without effect on each other, the equation of velocity has to be developed for each separately without regard to the others.

No experimental investigation of the law of coexistence has as yet been published. The application of this law in the theory of affinity leads, however, to results which agree with experience, and the law may therefore be considered to be experimentally proved.

Reversible Reactions.

The processes investigated above frequently represent only one part of the actual reactions. In many cases the substances formed mutually react to reproduce the original substances. In such cases the process does not end with decomposition; but a permanent final state is arrived at in which the original substances, as well as the products of their double decomposition, are coexistent. In such a case the final system is said to be in *chemical equilibrium*. Here we have to consider on the one hand the velocity of the reaction, on the other hand the proportion of the masses for which chemical equilibrium results. As aids in the first part of this inquiry we have the equations given above, together with the principle of coexistence: in investigating the second part of the problem we have the following condition;—*chemical equilibrium results when the velocities of the opposite reactions have become equal.*

The establishment of chemical equilibrium is connected with the second type of chemical reactions [equations (3) (4), and (5) (6)], respectively. For the velocity of each of the reactions we have

$$\frac{dx'}{dt}=k'x_1'x_2',\text{ and }\frac{dx''}{dt}=k''x_1''x_2'';$$

and equilibrium results when

$$\frac{dx'}{dt}=\frac{dx''}{dt}\text{ or }k'x_1'x_2'=k''x_1''x_2''.$$

This is the equation first established by Guldberg and Waage. Putting the initial quantities of the substances as p, q, p', and q', when the substances p' and q' are formed by the reaction of p and q and *vice versâ*, equilibrium will result when a certain quantity ξ of p and q has been decomposed. Then the quantities $p-\xi$, $q-\xi$, $p'+\xi$, $q'+\xi$ are in equilibrium; and ξ has the same value throughout, since the quantities p, q, &c. are measured according to equivalents. The quantity ξ may be positive or negative.

The equation of equilibrium then takes the following form:—

$$k'(p-\xi)(q-\xi)=k''(p'+\xi)(q'+\xi); \qquad (8)$$

from which a value for ξ is found,

$$\xi=\frac{k'(p+q)+k''(p'+q')}{2(k'-k'')}\mp$$
$$\sqrt{\left(\frac{k'(p+q)+k''(p'+q')}{2(k'-k'')}\right)^2+\frac{k'p'q'-k'pq}{k'-k''}} \qquad (9)$$

The minus sign holds when $\frac{k'}{k''}>1$, and *vice versâ*.

By making certain assumptions, this expression may be considerably simplified. If at the beginning of the reaction the substances p and q only are present, in equivalent quantities, $p=q$ and $p'=q'=o$, and it follows that

$$\frac{k'}{k''}=\frac{\xi^2}{(p-\xi)^2}\text{ and}$$

$$\xi=p\frac{\sqrt{\frac{k'}{k''}}}{\sqrt{\frac{k'}{k''}}+1} \qquad (9a)$$

The equation of velocity takes the following form. The resultant velocity $\frac{dx}{dt}$ is the difference of the partial velocities:

$$\frac{dx}{dt}=k'(p-x)(q-x)-k''(p'+x)(q'+x) \qquad (10)$$

Introducing a new constant h we have

$$h=\frac{k'(p+q)+k''(p'+q')}{k'-k''}-\xi;$$

the equation can then be brought to the form

$$\frac{dx}{dt}=(k'-k'')(\xi-x)(h-x);$$

and from this by integration, we obtain

$$\log\frac{h-x}{\xi-x}\cdot\frac{\xi}{p}=t(k'-k'')(h-\xi) \qquad (11)$$

The form of this equation is analogous to that already deduced for simple reactions (equation (6), p. 72). If now it is assumed, as before, that $p=q$, and $p'=q'=o$, ξ assumes the simple form given in (9a)

$$\text{and } h=p\frac{\sqrt{\frac{k'}{k''}}}{\sqrt{\frac{k'}{k''}}-1}$$

The preceding equations are deductions from the laws of the influence of mass, and the coexistence of chemical reactions. Both laws are of about the same importance in the theory of affinity as the laws of gravitation and the coexistence of motions are in astronomy.

Each individual practical case really comprises several different relations; but there are combinations in which so great a part of the result depends on one single cause, only, that the observed phenomena may be represented almost as if this were the only cause. And as little as we doubt the law of gravitation because the motions of the moon cannot yet be expressed completely in equations, so little have we cause to doubt the laws stated above because certain phenomena cannot yet be represented as simple deductions from them.

We have hitherto assumed that the constant of velocity does not alter its value throughout the whole reaction. It is, however, not impossible that reactions exist in which the reason for the change of k is to be found in the chemical process itself; in such cases the problem becomes considerably complicated.

Chemical Dynamics.

In general dynamics the magnitude of any force is defined and measured by the velocity which it imparts to a mass of known magnitude. Another way of measuring forces consists in establishing equilibrium between the given force and a force acting in the opposite direction, which latter is of a magnitude already known or easily determined. This can be considered as a special case of the first method, as a case in which the velocity due to the given force is reduced to nothing, by means of one equal in magnitude but opposite in direction. The second method, though not a direct one, possesses all the important experimental advantages belonging to a zero method and is therefore the more usual. The measurement of the intensity of chemical forces can be accomplished by two methods, analogous to those employed in general dynamics. The more usually employed method (because of experimental advantages) is the statical, or the method of equilibrium, in which a chemical process is reduced in a certain proportion by another action occurring in the opposite direction. This corresponds to the statical method used in measuring mechanical forces. Analogous to the kinetical method, or the method of velocity, is the process of obtaining a measure of the intensity of the acting forces by measuring the velocity of the chemical change. The two chemical methods are connected in a similar manner as the two mechanical methods, since, as has been shown above, the equilibrium of chemical changes can be regarded as the consequence of the mutual counteraction of changes which are equal in magnitude, but opposite in direction.

Statical Methods.

The first attempts to measure affinities were made by Wenzel, in 1777 (*Die Lehre von der Chemischen Verwandtschaft*, p. 28, Dresden, 1777). He used the method of velocities, but his process was very imperfect. His experiments related to the solution of metals by various acids. Later experiments dealt almost exclusively with the affinity between acids and bases, and were mostly carried out by the method of equilibrium.

Solutions of acids and bases were mixed in proportions such that different acids competed for an insufficient amount of a base, or *vice versâ*; and an attempt was then made to determine the distribution of the base between the competing acids (or *vice versâ*). Ordinary analyses could give no information as to this distribution; since such analyses could determine only the absolute quantities of the acids and bases, and not their distribution. Steinheil (*A.* 48, 153) (although with an entirely different aim) was the first to show how we must proceed in order to get a knowledge of the arrangement of the constituents of a solution without interfering with its composition. Since each of the constituents of a solution changes the physical properties—such as density, refractive index, colour, &c.—of the solution, a knowledge of the laws governing these changes indicates how to solve the problem, by measuring a sufficient number of constants and forming the necessary equations.

It has been already explained how Gladstone used these means for establishing a number of facts concerning the chemical statics of solutions of salts. He could not, however, utilise his measurements further, as there did not then exist a general theory of chemical affinity. Such a theory was first given by Guldberg and Waage (*Études sur les Affinités chimiques*, Christiania, 1867) and was also applied by them to a number of measurements. This theory has met with such wide confirmation that we hope to be able some day to reconcile with it those facts which do not appear at present to be in keeping with it.

J. Thomsen (*P.* 138, 65) was the first to apply the theory of Guldberg and Waage to the case of homogeneous solutions. He found that sulphuric acid when acting on soda gives a heat-production of 31,378 gram-units, while nitric acid gives 27,234 units only. Now, when sulphuric acid and nitric acid simultaneously act on soda, all three substances being present in equivalent quantities, three cases may arise. Either the sulphuric acid exclusively combines with the soda, or the nitric acid exclusively does so, or the soda divides itself between the two acids in some fixed proportion. In the first case 31,378 gram-units of heat, and in the second case 27,234 units, would be produced, while in the third case the heat-production would be represented by a number between these two. Therefore the number found by experiment gives a measure of the distribution of the soda between the acids.

Similarly sodium sulphate is allowed to react with nitric acid. If no chemical action results there will be no production of heat. If the nitric acid combines with all the soda, liberating all the sulphuric acid, a disappearance of heat must result, numerically equal to the difference between the two heats of neutralisation; that is to say, $31,378 - 27,234 = 4,144$ units of heat will disappear. If, however, a division of the base between the acids results, a quantity of heat less than 4,144 units will disappear. Experiment shows that 3504 units of heat are used; therefore the soda divides itself between the two acids.

If no secondary thermal action takes place between the substances used in the experiment, we can deduce directly from these numbers that $\frac{3504}{4144} = 0{\cdot}845$ of the total quantity of sodium sulphate is decomposed. Free sulphuric acid does, however, react with sodium sulphate, and the action is accompanied by production of heat. The extent of the reaction depends on the relative quantities of the reacting substances present. Thomsen has measured this effect for a great many proportions, and has expressed his results by the equation:

$$Q = -\frac{n}{n+0{\cdot}8}.3{,}300 \text{ gram-units of heat};$$

where n represents the number of equivalents of sulphuric acid present for each equivalent of sodium sulphate. By the help of this formula Thomsen found empirically that soda divides itself in such a proportion that $\frac{1}{3}$ of it goes to the sulphuric acid, and $\frac{2}{3}$ of it to the nitric acid. Calculating the heat production on this supposition, the result is $-3{,}547$; experiment gives $-3{,}504$; the difference lies within the limit of experimental error.

Guldberg and Waage's theory gives an extremely simple expression for this case. Since sodium sulphate and nitric acid were present in equivalent quantities at the beginning of the reaction, but sodium nitrate and sulphuric acid were absent, we have to put in equation (8)

$$p = q = 1 \text{ and } p' = q' = 0;$$
$$\text{this gives } k(1-\xi)^2 = k'\xi^2,$$
$$\frac{k}{k'} = \frac{\xi^2}{(1-\xi)^2}$$

As ξ is the quantity of soda combined with the nitric acid, and $(1-\xi)$ that combined with the sulphuric acid, it follows that the ratio of the velocities of the reaction is equal to the square of the ratio of distribution. Thomsen calls the endeavour of the acids to combine with bases the *avidity* of the acids, and defines it by the ratio of distribution. According to this, the avidity of sulphuric acid is half as great as that of nitric acid, or putting the latter $=1$, the avidity of sulphuric acid is $=0{\cdot}5$. The *avidities* are in the ratio of the square roots of the velocities of reaction.

Thomsen (*Thermochemische Untersuchungen*, i. 308) has made further experiments concerning the avidity of other acids towards soda, using a method similar to that described above. His numbers are given in the following table, where the avidity of nitric acid has been put $=1{\cdot}00$.

Hydrochloric acid .	=1·00
Hydrobromic „ .	0·89
Hydriodic „ .	0·79
Sulphuric „ .	0·49
Selenic „ .	0·45
Trichloracetic „ .	0·36
Orthophosphoric acid .	0·25
Oxalic „ .	0·24
Monochloracetic „ .	0·09
Hydrofluoric „ .	0·05
Tartaric „ .	0·05
Citric „ .	0·05
Acetic „ .	0·03

Boric, silicic, and hydrocyanic acids do not give any appreciable values.

Taking the squares of these numbers we get the relative velocities of the reactions between the acids and the soda, which values cannot be obtained directly owing to their great magnitude.

The question now presents itself as to whether the *avidities* thus found have constant values, or whether they change when a base other than soda is employed. Thomsen made similar experiments for hydrochloric and sulphuric acids, using different bases (*P.* 138, 497), viz. potash, ammonia, and magnesia, the oxides of manganese, iron, cobalt, nickel, zinc, and copper; for the avidity of sulphuric acid he obtained numbers which increase from 0·5 up to 0·8, and vary, for the alkalis between 0·5 and 0·57, and for the bases of the magnesia series between 0·70 and 0·81. These results induced Thomsen to conclude that the relative avidity of acids depends on the nature of the base.

Berthelot (*A. Ch.* [4] 30, 516), however, raised the just objection that Thomsen's method does not allow of the measurement of the relative avidities without the introduction of errors. The free sulphuric acid reacts on the neutral salt, forming acid sulphate, and thus loses part of its active power, and it does this the more the greater the quantity of acid-sulphate which can be formed.

Thomsen's experiments were repeated by W. Ostwald (*P. Ergzbd.* 8, 167; *J. pr.* [2] 19, 468), who used a different method based on measuring the changes of volume which accompany chemical reactions in aqueous solutions. The volume of the solution of a salt is different from the sum of the volumes of the solutions of the acid and the base, which by their mutual action produce the salt; and further this change of volume is different for different bases and acids. If we use solutions which contain one gram-equivalent of the acid or base per kilogram of solution then the volume of two equivalents of soda is 1913·26 c.c., and that of two equivalents of nitric acid is 1933·25 c.c.; the sum of these two is 3846·51 c.c.; but the volume of the corresponding solution of sodium nitrate is 3886·05 c.c., that is to say, 39·54 c.c. more than the sum of the volumes of acid and base. Repetition of the experiment with sulphuric acid gives an increase of volume of 29·96 c.c. only. Hence the volume-changes can be used for determining the composition of the solution, in the same manner as the heats of neutralisation had been used by Thomsen. Results were obtained by this method exhibiting the behaviour of nitric acid and sulphuric acid towards soda; these results agreed entirely with those of Thomsen. Thomsen's conclusion that nitric and hydrochloric acids are stronger acids than sulphuric acid—a result opposed to the older views—was thus confirmed by Ostwald. The same chemist investigated at length the question as to whether the relative affinity of an acid varied with the nature of the base. By experiments to which Berthelot's objection cannot apply, he arrived at the result that *the relative avidity of an acid is independent of the base.* Thus with hydrochloric and nitric acids he found the following numbers:—

Potash . .	0·97
Soda . . .	0·96
Ammonia . .	0·96
Magnesia . .	0·99
Zinc oxide .	0·95
Copper oxide .	0·97

The differences are not greater than the probable errors of the experiment.

The question concerning the influence of temperature on the relative affinities of acids has also been investigated by Ostwald. He measured the expansion due to heating the same solutions which had served for the volumetric experiments with soda. The ratio of the avidity or affinity of hydrochloric acid to that of nitric acid towards soda proved to be as follows:—

At 0°	.	1·02
20°	.	0·96
40°	.	0·98
60°	.	1·00

In both cases the number for sulphuric acid is not quite constant; but, as already mentioned, this acid seems to be the stronger the less acid sulphate is formed, and *vice versâ*.

At a subsequent time Thomsen (*Thermoch. Unters.* i. 89) also attacked the problem of the influence of temperature on relative avidities, and arrived at the same results as Ostwald.

The refraction of light was used by Ostwald as another method for determining the composition of a homogeneous solution by means of its physical properties. Dale and Gladstone (*T.* 1863, 317), and also Landolt (*P.* 133, 1), showed that the function $v(n-1)$, in which n is the refractive index and v the specific volume of a liquid body, depends only on the elementary composition of the body and not on the temperature, nor (within certain limits) on the chemical arrangement of the constituents of the body. Hence the specific volume is inversely proportional to the refractive index diminished by 1, and the volume-changes attendant on chemical reactions must be accompanied by opposite changes in the refractive indices. Experiment has most fully borne out these conclusions. The optical method is, however, less accurate than the volumetric method, when the ordinary apparatus only is used.

The numerical results of Ostwald's experiments are collected in the following table. The numbers have the same meaning as those of Thomsen given before (p. 75), *i.e.* they give the relative avidities of the various acids, putting that of nitric acid = 1.

Acid		Thomsen
Nitric . . .	1·00	1·00
Hydrochloric . .	0·98	1·00
Trichloracetic . .	0·80	0·36
Dichloracetic . .	0·33	—
Monochloracetic .	0·070	0·09
Glycolic . . .	0·050	—
Formic . . .	0·039	—
Citric . . .	0·033	—
Acetic . . .	0·0123	0·03
Propionic . . .	0·0104	—
Butyric . . .	0·0098	—
Isobutyric . .	0·0092	—
Succinic . . .	0·0145	—
Malic . . .	0·0282	—
Tartaric . . .	0·052	0·05

Thomsen's values have also been given as far as they refer to the acids considered here. They agree as well as can be expected; trichloracetic acid alone shows an appreciable difference. Thomsen's number for this acid is undoubtedly much too small; this has been proved beyond doubt by other measurements.

The ratios of avidities given in the preceding table remain the same whether determined for potash, soda, or ammonia; they are independent of the nature of the base.

Besides these three methods which are of general application to the case of solutions, some investigators have employed others, which can, however, be used only in special cases. Thus G. Wiedemann (*W.* 5, 45) has shown that from the magnetic properties of ferric salts in solution we can argue as to the amounts of these salts decomposed by the water into free acid and colloidal soluble iron oxide. This method is, however, restricted to the case of these special salts. A. Müller (*P. Ergzbd.* 6, 123) has drawn conclusions from the change in colour as to the distribution of iron oxide between hydrochloric acid and sulphuric acid. Jelett (*I.* 25, 371) determined the relative affinities of codeine, quinine, and brucine, by means of the rotation of the plane of polarisation, and found for the influence of mass the same law as had been established by Guldberg and Waage. The experiments of Dibbits (*P. Ergzbd.* 7, 462), Brücke (*Sitz. W.* 77, April 1877), and others, are of a more qualitative nature.

Besides these statical methods, based on the determination of the composition of a homogeneous solution, others are available in which the chemical reactions take place in heterogeneous media, viz. between solids and liquids, or liquids and gases, or lastly between solids and gases. The theory of these methods has been also given by Guldberg and Waage, and Ostwald has developed the methods for the purpose of determining affinities.

According to Guldberg and Waage the chemical action of solids in contact with solutions is independent of their mass; in other words, the *chemical mass* of the solids is constant. Otherwise the laws of the influence of mass hold good. If, for example, an acid acts on the salt of another acid, which latter salt is insoluble in water (or more strictly, scarcely soluble), and with the base of which the first acid forms a soluble salt, then the same equation holds good as applies in the case of substances which are all soluble, with this exception that the term corresponding to the insoluble salt becomes constant or independent of x. Putting in the equation $k.p.q = k'.p'.q'$ p = hydrochloric acid, and q = calcium oxalate, then p' = calcium chloride, and q' = oxalic acid.

If the experiment is arranged so that hydrochloric acid acts on an excess of calcium oxalate and that undissolved calcium oxalate is always present, then at all stages of the change oxalic acid and calcium chloride are present in equivalent quantities. Putting the original quantity of hydrochloric acid = 1, and that of the oxalate dissolved = ξ, the equation becomes

$$k(1-\xi)c = k'.\xi.\xi\text{; hence}$$

$$\frac{k}{k'} = \frac{\xi^2}{c(1-\xi)},\text{ and } \sqrt{\frac{k}{k'}} = \phi = \frac{\xi}{\sqrt{c(1-\xi)}}$$

where c stands for the constant chemical mass of calcium oxalate. In this equation k, k', and c are unknown, while ξ can be measured directly. Repeating the experiment with a different acid, say nitric acid, a new expression of the form

$$\phi_1 = \frac{\xi_1}{\sqrt{c(1-\xi_1)}}$$

is obtained, in which c has the same value as referring to calcium oxalate, which is used in both experiments under the same conditions. Dividing the one equation by the other we get the relative affinities

$$\phi:\phi_1 = \frac{\xi}{\sqrt{1-\xi}} : \frac{\xi_1}{\sqrt{1-\xi_1}}$$

expressed in quantities which can all be directly measured. This method has been used by W. Ostwald and his pupils for determining the relative affinities of various acids, and has given results which agree well with those found for homogeneous solutions. It has great experimental advantages over the physical methods, as the ordinary methods of chemical analysis can be used. The insoluble, or scarcely soluble, salts used were these; *zinc sulphide, calcium oxalate, zinc oxalate, barium chromate, cream of tartar*, and the *sulphates of barium, strontium*, and *calcium*. As a rule the coefficients of affinity thus determined for various salts agree very well amongst themselves, but there are some deviations which are not yet fully explained.

As an example of the method the following numbers are given (*J. pr.* [2] 28, 493); these numbers were obtained by the action of acids on calcium oxalate, a substance lending itself particularly well to these experiments. Experiments were made both with normal and decinormal solutions of acids. Nitric acid is again put = 1.

Acid	Normal	$\frac{1}{10}$ Normal
Hydrochloric . .	1·00	0·98
Hydrobromic . .	0·95	0·99
Nitric . . .	1·00	1·00
Chloric . . .	1·04	1·00
Sulphuric . . .	0·70	0·74
Formic . . .	0·0259	0·129
Acetic . . .	0·0105	0·735
Monochloracetic .	0·051	0·213
Dichloracetic . .	0·183	0·188
Trichloracetic . .	0·612	0·899
Lactic . . .	0·041	0·133
Succinic . . .	0·0205	0·093
Malic . . .	0·0505	0·121
Tartaric . . .	0·0462	0·141
Citric . . .	0·0306	0·144

The numbers in the first column, which refer to normal solutions (one gram-equivalent in a litre), agree well with those before obtained by the volumetric method. Along with them is given a second series referring to solutions ten times as dilute. While the stronger acids exhibit scarcely any change by the dilution, the values for the weaker acids have increased very considerably, and this the more the weaker are the acids. We shall consider this phenomenon at length later on, and find the general law underlying it.

Of further results which have been arrived at by this method one must be noticed as important, viz. that the action of the acids varies as they are present alone or along with their neutral salts (*J. pr.* [2] 28, 209).

Some such result was to be expected in the case of dibasic acids which combine with their neutral salts to form acid salts. The monobasic acids, however, exhibit no tendency to combine with their neutral salts, and yet they too show a change which in the case of the strong acids, such as hydrochloric and nitric, is an increase in the affinity. This increase is proportional to the quantity of the neutral salt present, and decreases rapidly with increasing dilution. This statement does not, however, hold for all monobasic acids, but only for the strong acids. The weak monobasic acids, on the contrary, are considerably more weakened by the presence of their neutral salts, and this the more the weaker are the acids. These facts are of great importance in the interpretation of experiments undertaken for the purpose of determining the relative affinities of acids by the division of a base between two competing acids. Since in this case the acids always act in presence of their own salts, this condition doubtlessly exerts some influence, making the strong acids appear stronger and the weak acids appear weaker. This shows that too much importance must not be attached to the numerical values obtained by the preceding methods; they certainly give the order of the affinities correctly, but the numerical values deviate from the true value in the sense that the large numbers are too large and the small values are too small. We shall see later on that other determinations of the same quantities, which are more likely to give the true values, show deviations in this sense from the above numbers.

Kinetical Methods.

The second way of measuring the intensity of chemical forces is based on determinations of the velocities of the reactions produced by these forces. The theoretical introduction concerning this method has been already considered, and we have seen that many reactions proceed according to a course which agrees well with that calculated from the influence of mass.

This method does not, however, lend itself to direct applications to the majority of the reactions investigated by the statical method. This statement applies particularly to the effects of affinity between acids and bases, because these processes are of too short duration to allow of measurements being accurately made of their velocities. If, however, the magnitudes in question can be measured by kinetical methods, this is because of a general and important principle.

It has been already shown that the nature of the base exerts no influence on the relative avidities or affinities of the acids which react with the base. If the affinity between an acid a and a base b is designated by $f(a, b)$, then the following equations hold good:

$$\frac{f(a, b)}{f(a', b)} = \frac{f(a, b')}{f(a', b')} = \frac{f(a, b'')}{f(a', b'')}.$$

These equations can be true only if each expression $f(a, b)$ is the product of two factors one of which depends on the acid only and the other on the base only; $f(a, b) = \phi(a).\psi(b)$.

The affinity between acids and bases is therefore the product of *specific affinity-coefficients*. All reactions due to acids and bases as such must, on this view, be proportional among themselves. From this it follows that processes which, taken by themselves, have nothing to do with the formation of salts, may be employed for finding numerical values for the affinities which come into play during the formation of salts, provided the reactions in question have been accomplished by the acids and bases only. Determinations of the specific affinity-coefficients of acids and bases are thus of the greatest importance. It will be our task to show first that the above conclusions are verified by experiment, and then to use the numbers thus arrived at for drawing further deductions.

The first reaction which was used to check the values of the coefficients of affinity of acids determined in the statical way, by means of a kinetical method, was the change of acetamide into ammonium acetate (Ostwald, *J. pr.* [2] 27, 1), which takes place according to the equation $CH_3CONH_2 + H_2O = CH_3COONH_4$. When water only is present the reaction does not proceed to a sensible extent, but when an acid is added the latter exerts a *predisposing* influence, and the process takes place to the degree which is possible under the existing conditions of affinities, concentration, and temperature.

By 'predisposing affinity' is usually understood the cause of reactions between certain substances, which reactions could take place, but do not actually occur, without the presence of another substance, which has affinity towards one of the possible products of the reaction. In the case just discussed, water and acetamide do not react unless an acid capable of combining with the ammonia produced (or a base which has affinity for acetic acid) is present. The strange assumption expressed in the name *predisposing affinity*, viz. that the affinity of the predisposing substance towards a body not yet formed induces the other substances to produce this special body, has been given up, since the molecular theory of Williamson and Clausius, as developed by Pfaundler, gives a much more simple view of such reactions. When applied to the case just considered, this theory tells us that the atoms which form the molecules of acetamide and water only very seldom get a chance of forming ammonium acetate during the movements and collisions of the molecules in question, since the forces which tend to retain the original condition of the system are greater than the forces which tend towards decomposition. If, however, a strong acid or base is added, the forces tending towards decomposition are correspondingly increased, and, in many collisions, in which previously no change occurred, decomposition now takes place (*v.* also Mendeléeff, *B.* 19, 456).

The experiments were conducted by keeping equivalent quantities of acetamide and acid for some time at 65° and 100°. The quantity of ammonium salt formed was determined by decomposing it with sodium hypobromite and measuring the volume of nitrogen evolved. The reaction takes place in the presence of acids, such as hydrochloric acid, according to the equation,

$$CH_3CONH_2 + H_2O + HCl = CH_3COOH + NH_4Cl.$$

Three different kinds of molecules are therefore always necessary for the reaction. Moreover, only two substances, acetamide and hydrochloric acid, undergo an appreciable change of mass during the reaction. The water is present in such excess (about 800 H_2O to 1 HCl) that the change in its mass is unappreciable. Hence, if there are no secondary reactions, the change will proceed according to equations (3) and (4). An example in which the actual reaction agrees with theory has already been given.

But the reaction is by no means free from secondary changes. Particularly (as has been already noticed), the presence of the neutral ammonium salt of the acid added has the effect of increasing the strength of strong acids, and decreasing the strength of weak acids. Consequently when strong acids are used the process is accelerated, compared with its normal value, and the acceleration is the greater the further the change has proceeded. With weak acids, on the other hand, the process is retarded. Owing to the formation of acid salts, the polybasic acids are influenced by similar but much more pronounced secondary reactions. All these conditions have to be taken into account in the investigation of the progress of the reaction, as is seen most conspicuously in the graphical representation given in the original paper. These circumstances are disadvantageous if it is desired to make absolute determinations of the velocity of the reaction, but they are of advantage in the comparison of the kinetical and statical methods, since the results obtained by the latter are also influenced in the same way by similar sources of error.

The time taken to convert half the acetamide into the ammonium salt was taken as the reciprocal measure of the velocity of the reaction. The velocity in minutes was found to be as follows:—

Acid	At 65°	At 100°	Ratio
Hydrochloric .	72·1	4·98	14·5
Nitric . . .	75·2	5·35	14·4
Hydrobromic .	74·0	5·14	14·4
Trichloracetic .	112·8	—	—
Dichloracetic .	433·7	—	—
Monochloracetic .	4,570	—	—
Formic . . .	28,950	2,138	13·6
Sulphuric . .	180	14·1	12·8
Oxalic . . .	1,516	118·6	12·8
Tartaric . .	35,310	929	14·7
Malic . . .	—	—	—
Succinic . .	—	7,976	—
Citric . . .	44,810	3,088	14·5
Phosphoric . .	—	3,880	—
Arsenic . .	—	4,005	—

In order to make these numbers comparable with the coefficients of affinity as found by the volumetric method they must be referred to HCl = 1, by dividing the times corresponding to the several acids each into that corresponding to hydrochloric acid. The relative velocities of the reaction are thus obtained for hydrochloric acid = 1. Further it must be borne in mind that by theory the ratio of the affinities is equal to that of the square roots of the velocities of the reaction. In the following table I have collected the acids the relative affinities of which are known. Under I. are given the velocities of the reaction, under II. their square roots, and under III. the relative affinities:—

Acid	I.	II.	III.
Hydrochloric .	1·00	1·00	0·98
Nitric . .	0·96	0·98	1·00
Hydrobromic .	0·97	0·98	0·95
Trichloracetic .	0·639	0·80	0·80
Dichloracetic .	0·166	0·41	0·33
Monochloracetic	0·0169	0·13	0·07
Formic . .	0·00266	0·052	0·039
Acetic . .	0·000547	0·0234	0·0123
Sulphuric . .	0·428	0·65	0·67
Tartaric . .	0·00564	0·075	0·052
Malic . .	0·00218	0·0467	0·0282
Succinic . .	0·00065	0·0255	0·0145

The numbers in the two last columns agree as well as could be expected. The deviations are in the direction of a greater value for II. than for III. in the case of weak acids. The reason for this lies in the fact that in the enunciation of the equation of velocity no attention was paid to the acetic acid formed in the reaction, by the presence of which the change is accelerated. This action of acetic acid scarcely comes into play when strong acids are employed.

The examination of the action of acids on the change of acetamide into acetic acid and ammonium salt has established the connection between equilibrium and velocity which is predicted by theory; but the reaction employed was not of a kind to give completely accurate values for the velocity of the change, since too many secondary reactions exert their influence on the primary process. Another reaction studied by Ostwald (*J. pr.* [2] 28, 449) lends itself better for this purpose. This is the decomposition of ethereal salts by water in the presence of acids. Aqueous solutions of methyl acetate (or of similar compounds) undergo only very slow decomposition at ordinary temperatures; if, however, an acid is present the process is greatly accelerated. The acid does not undergo a permanent change, since at the end of the reaction exactly the same quantity of acid is found as was present at the beginning. It is doubtless by its affinity for the methyl alcohol that the acid influences the rate of the change. It *predisposes* in the sense already explained, only the compound which the acid forms with the methyl alcohol cannot exist in the presence of the great excess of water. The chemical process is represented by the equation $CH_3COOCH_3 + H_2O = CH_3OH + CH_3COOH$. Two substances are required; but the quantity of water is so great that its change need not be taken into account. Equations (1) and (2) must therefore hold good. This conclusion is verified by experiment. Thus for example 10 c.c. of normal hydrochloric acid were mixed with 1 c.c. of methylacetate and diluted with water to 15 c.c. One c.c. of this solution required for neutralisation 13·33 c.c. of baryta. Owing to the decomposition of the methyl acetate the acidity increased; the results are given in the first table of next column. The numbers in the last line represent the results when the decomposition was completed.

In the third column, under x, is given the increase in the number of c.c. of baryta used to neutralise the acid; the values in this column are always proportional to the quantity of methylacetate decomposed. The last value 14·11 gives the quantity a in the equation

$$\log \frac{a}{a-x} = kt.$$

Calculating the expression $\log \frac{a}{a-x}$ (for simplicity's sake in ordinary logarithms), and dividing it by the time t, k (= the coefficient of velocity) is obtained; the value of k is given in the last column; it is nearly a constant.

		x	k

Racemic . . .	0·0[illegible]296	0·1515
Citric . . .	0·01[illegible]	0·1279

In the second column I have given the square roots of the velocities of reaction; these numbers ought to be proportional to the affinities, if the determination of the affinities were free from the influence of all secondary reactions. Comparing these numbers with those already obtained, the same order of affinities appears, but in this case the values are more nearly equal. This agrees entirely with what had been expected; for it has been often emphasised that, owing to the presence of neutral salts, the statical methods make the strong acids appear too strong, and the weak acids appear too weak. The numbers found in the present case can therefore be justly considered as approaching nearer to the true coefficients of affinity than the previous values.

It is of special interest that a reaction such as the catalysis of methylacetate, which is only very remotely connected with the process of the formation of salts, is yet doubtlessly brought about by that very property of acids which produces the latter class of reactions. This leads to the conclusion that the numerical values of all reactions exhibited by acids as such depend on that one property which till now has been somewhat vaguely termed the *strength* of the acids. In order to verify this assumption Ostwald (*J. pr.* [2] 29, 385, [1884]) investigated another process which is not connected with the formation of salts, viz., the inversion of cane sugar. The reaction proceeds, as in the case of methylacetate, by the addition of water—$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6$—without an apparent intervention of an acid. Yet it takes place only in the presence of acids. It is a catalytic reaction in the same sense as that already considered. As again only one substance, the sugar, undergoes change, the same equation holds good. As an example has already been given which shows that the process is represented by equations (1) and (2), the velocities of inversion are now given directly (*v.* table in last column).

Arsenic . . .	0·0481	0·219	—

In the second column are given the square roots of the velocities of inversion, in the third column the corresponding values for the catalytic change of methylacetate. The agreement is evidently sufficiently great to prove the identity of the causes which produce the inversion of cane sugar and the decomposition of methyl acetate. This agreement also forms the complete experimental verification of the assumption that there exist constants of specific activity, which numerically determine all the manifestations of affinity exerted by acids as such. The numbers found for methylacetate and for cane sugar represent these constants with great exactitude. The process of the inversion of cane sugar had been already used by Löwenthal and Lenssen (*J. pr.* 85, 321, 401) for the purpose of measuring constants of affinity. These chemists did not, however, deduce the constants of inversion from their experiments, although the theory of inversion had been established long before by Wilhelmy (*P.* 81, 413), nor did they give a proof of the fact that there are other chemical reactions which proceed according to a course analogous to that observed by them in the inversion of cane sugar.

Besides the chemical methods for the determination of the affinities of acids, there is yet another method which, by means of physical measurements, allows very accurate determination of these values to be made. It has been proved beyond doubt that the electrolytic conductivities of acids are closely connected with their chemical properties; so that this conductivity is proportional to the velocity of the reactions produced by the acids. As the electrolytic conductivity can easily be measured to a high degree of accuracy, we have here a method of much importance for the solution of the problems connected with affinity. The existence of this relation was first recognised and enunciated by W. Hittorf (*W.* 4, 391), who had, however, almost no measurements at his disposal. Arrhenius (*Bijh. K. Svensk. Vet. Ak. Hand.* 8, Nos. 13, 14 (1884)) developed a theory of the chemical changes among electrolytes, starting with the supposition that the power of conducting electrolytically and the power of participating in chemical reactions were identical.

This theory leads to equations which agree with those of Guldberg and Waage. Finally W. Ostwald has considerably increased the somewhat scanty material available for comparisons between the power of inducing chemical reactions and electrolytic conductivity. He fully proved the proportionality between the velocity of the reactions induced by an acid and the electrolytic conductivity of the acid (*J. pr.* [2] 30, 93; *ib.* 30, 225 [1884]; *ib.* 31, 433; *ib.* 32, 300 [1885]). The following table shows this agreement. Under I. are given the electrolytic conductivities for normal solutions; under II. the velocities of inversion of cane sugar for seminormal solutions; under III. the velocities of decomposition of methylacetate for ½ normal solutions; all the numbers are referred to hydrochloric acid = 1.

Acid	I.	II.	III.
Hydrochloric	1·002	1·00	1·00
Hydrobromic	1·01	1·11	0·98

The agreement of the numbers in the three columns is evident, and proves the truth of the assertion made above.

In order to understand the relation between conductivity and the power of taking part in chemical changes, we must go back to the theory of Clausius and Williamson. According to this theory the molecules of the electrolytic substances are continually interchanging their constituent atoms. These atomic exchanges generally take place to an equal amount in all directions; but when an electric current is passing they are so influenced that the electropositive or basic constituents go to the one side, and the electronegative or acid constituents to the other side, each constituent separating from the solution on one of the electrodes. This motion of the constituents occurs to a greater extent the greater the difference of potential between the electrodes, *i.e.* the greater the electromotive force. The change proceeds according to Faraday's law of electrolysis, which states that the quantity of electricity passed is proportional to the equivalents of the parts of the molecules separated out. Put into a slightly different form, this means that each electrified atom, or group of atoms, conveys the same quantity of electricity *quite independently of its nature.*

Since the electric current only exerts a directive influence on the electrolyte, but does not itself induce the action, the conducting power of substances depends entirely on the power of interchanging their ions. But on that same power depends also the velocity of the chemical changes produced by these substances; hence it follows that the velocities of the reactions must be proportional to the conductivities of the reacting substances. The experimental proof of this proportionality is in itself an important point in favour of the theory of Williamson and Clausius. (In Faraday's works we also find views which agree in the chief points with those explained above.) For the experimental details of the method the reader must be referred to the papers of Kohlrausch, Arrhenius, and Bouty. A short account of the conceptions and definitions used will, however, be given here, since the assumptions generally used in physics proper do not lend themselves well for our purpose.

Imagine a vessel having the form of a parallelopiped, the two parallel sides of which form the electrodes, and imagine the distance between the two to be equal to unit length. Into this vessel we imagine a quantity of the electrolyte to be placed, either by itself or in solution, such that its weight in grams is numerically equal to its molecular weight. Let us further suppose that the electromotive force between the two electrodes is unity; then the quantity of electricity passed through in unit time represents the molecular conductivity. Since equal quantities of electricity are conveyed by each electrolytic molecule, the total quantity of electricity passed is proportional to the number of double exchanges which take place in unit of time in one molecular weight of the substance

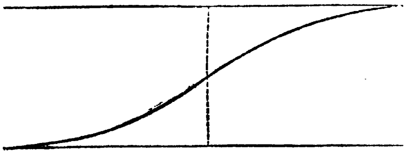
The electrolytic conductivity can be very easily and accurately determined. The possibility of solving a great many problems connected with the values of affinities is thus presented. W. Ostwald has specially investigated the influence of dilution, and has established the laws which hold for it. The simplest relations are found for the strong monobasic acids, hydrochloric, hydrobromic, hydriodic, nitric, chloric, and perchloric. For normal solutions all these acids have nearly the same conductivity, and this increases by about 10 per cent. to 12 per cent. with increasing dilution, gradually approaching a maximum value, which in the units used by Ostwald was equal to 90. Sulphocyanic and bromic acids approximate to the acids named above.

The other monobasic acids, which are weaker, and which therefore have smaller conductivities than those already mentioned, exhibit a greater change in conductivity with increasing dilution, the weaker they are, and they all do this according to the same law. This law states that *the dilutions at which two acids have the same molecular conductivity always bear the same ratio to each other.*

Thus, when measured in the units mentioned above, formic acid of the dilution 2—*i.e.* $H_2CO_2 = 46$ grams, in two litres of the solution—has the molecular conductivity 1·76; butyric acid reaches the value 1·81 only at 32 litres dilution. On further dilution the following relation is manifested:—

Formic Acid		Butyric Acid	
Dilution	Conductivity	Dilution	Conductivity
4	2·47	64	2·56
8	3·43	128	3·50
16	4·80	256	5·04
32	6·63	512	7·02
64	9·18	1024	9·74
128	12·6	2048	13·4
256	17·0	4096	18·0
512	22·4	8192	23·8
1024	29·0	16384	31·5

Butyric acid and formic acid have always nearly the same molecular conductivity when the former is sixteen times as dilute as the latter. The same holds good for dilute solutions of all the monobasic acids. Plotting a curve, with the molecular conductivities as ordinates and the logarithms of the dilutions as abscissæ, we find it to have the shape indicated in the annexed figure. In this, the logarithms are not referred to the base 10, but to the base 2, since in Ostwald's experiments the dilutions increase as the powers of two. They are the exponential powers, p, of the dilution v; $v = 2^p$.



The curve appears to be symmetrical about two lines at right angles to each other, and has a point of contrary flexure when the conductivity reaches the value 45. The equation to the curve can be approximately expressed—using the given units—by the empirical formula

$$\tan. m = \left(\frac{v}{v_0}\right)^{\cdot 4518}$$

where m is the molecular conductivity; v_0 the dilution (in litres per gram-equivalent) for which the conductivity is 45; and v any dilution for which the conductivity is to be calculated. The same curve holds for all acids if the abscissa v_0 is chosen properly. The value v_0 is characteristic for each acid. For the above-mentioned strong acids, it is found in high concentrations:—for iodic acid, at 2·8 litres approximately; for hypophosphorous acid, 8 litres; for dichloracetic acid, at 10 litres; for monochloracetic acid, between 400 and 500 litres; for formic acid, at about 1000; and for butyric acid, at about [illegible]0,000 litres.

The influence of the dilution on the relative affinities varies widely for the different acids, as has already been seen. It seemed therefore very doubtful whether much importance could be attached to these values as natural constants on which the action of the acid as such depends. In the law of dilution, as enunciated above, there has been found the proof that we are dealing with important and characteristic values, with values which do not alter with the nature of the reaction induced by the acid, and which are related to the dilution in a perfectly fixed manner. The general truth of this law for the case of chemical reactions has been separately proved by Ostwald (*J. pr.* [2] 31, 307). The values of affinities sought by men of science in the last century have thus been found by means of a method which had been even then indicated by the famous opposer of the old theory of affinity.

It has already been mentioned that the above law of dilution holds primarily for monobasic acids. Polybasic acids behave differently according to their constitution. Some dibasic acids, such as phosphorous, selenious, &c., in which the second hydrogen atom is of the nature of a weak acid (this is shown by the alkaline reaction of their normal salts), behave on dilution at first exactly like monobasic acids, the conductivity being referred to molecular and not to equivalent weights. Hence electrolysis of these solutions takes place at first according to the type H | HR″. It is only on reaching very great dilutions that the second hydrogen atom begins to participate in the reaction. Dibasic acids whose normal salts are neutral behave differently. It is true that they, too, conduct at first according to the type H | HR″; but the second hydrogen atom exerts its influence even in moderately dilute solutions. The conductivity increases much more rapidly than in the case of monobasic acids, and approaches a maximum which is double that observed for monobasic acids. Oxalic acid may be taken as a typical acid of this class. In the case of very strong dibasic acids, such as sulphuric acid, it is the last part of the phenomenon just described which becomes prominent. Even for a concentrated solution the molecular conductivity exceeds the maximum of monobasic acids, and rapidly approaches a value double that found with these acids. Hence conduction takes place from the beginning, for the most part, according to the type H_2 | R″.

Ostwald has recently (*J. pr.* [2] 32, 300) examined the conductivity of a number of acids, and has shown that the relations already stated hold in all cases. He has also established many relations between the conductivities of acids and their chemical constitution. This investigation opens up the possibility of drawing many inferences concerning the action of chemical forces. The following tables exhibit an abstract of the measurements of the molecular conductivities of various acids for the dilutions of 4, 32, and 256 litres:—

Acid	4 litres	32 litres	256 litres
Hydrochloric HCl .	80·9	87·0	89·2
Hydrobromic HBr .	83·4	87·9	89·6
Hydriodic HI .	83·2	89·6	89·7
Hydrofluoric HF .	6·54	13·14	30·3
Hydrocyanic HCN .	0·077	0·108	—
Sulphocyanic $HSCN$.	79·3	84·2	86·5
Sulphydric H_2S . .	—	0·214	—
Ferrocyanic $H_4Fe(CN)_6$	—	205·9	250·7

The acids which do not contain oxygen show great differences: HCl, HBr, HI, form a group of strong acids, while HF is much weaker; HCN can scarcely be called an acid; H_2S is slightly stronger; but if cyanogen combines with sulphur and hydrogen sulphocyanic acid is formed the strength of which approaches that of hydrochloric acid. Ferrocyanic acid is also a strong acid, though made up of the neutral iron cyanide and the weakly acid hydrogen cyanide.

Acid	4 litres	32 litres	256 litres
Nitric HNO_3 . .	80·4	86·3	88·4
Chloric $HClO_3$ . .	80·2	85·3	88·7
Perchloric $HClO_4$ . .	82·2	88·1	89·9
Bromic $HBrO_3$ . .	—	79·4	86·3
Iodic HIO_3 . . .	50·6	72·3	81·8
Periodic H_5IO_6 . .	23·7	49·2	76·7

HNO_3, $HClO_3$, $HClO_4$ closely follow the halogen hydracids; $HBrO_3$ is weaker; HIO_3 is still weaker; and H_5IO_6 shows this decrease in strength to a marked extent. A similar relation is shown by the acids of phosphorus.

Acid	4 litres	32 litres	256 litres
Hypophosphorous H_3PO_2	37·91	62·1	77·84
Phosphorous H_3PO_3 .	34·29	56·96	74·54
Orthophosphoric H_3PO_4	17·00	34·41	61·8

Here too the acids become weaker as the amount of oxygen increases. The opposite relation is shown by the acids of sulphur and selenion.

Acid	4 litres	32 litres	256 litres
Sulphurous H_2SO_3 .	19·19	41·6	66·5
Sulphuric H_2SO_4 . .	96·4	116·3	150·6
Dithionic $H_2S_2O_6$ . .	—	166·4	178·0
Tetrathionic $H_2S_4O_6$.	—	170·6	181·5
Selenious H_2SeO_3 . .	9·74	21·73	45·11
Selenic H_2SeO_4 . .	103·2	127·0	157·9

The strength increases with increase of oxygen as well as with increase of sulphur.

As regards organic acids, the members of the acetic series are weak acids, and the strength decreases as we ascend in the homologous series.

Acid	4 litres	32 litres	256 litres
Formic HCO_2H .	2·47	6·63	17·0
Acetic CH_3CO_2H . .	0·755	2·12	5·64
Propionic $C_2H_5CO_2H$.	0·601	1·77	4·92
Butyric $C_3H^{\alpha}_7CO_2H$.	0·604	1·81	5·01
Isobutyric $C_3H^{\beta}_7CO_2H$.	0·608	1·81	4·95
Valeric $C_4H_9CO_2H$.	0·615	1·87	5·16
Caproic $C_5H_{11}CO_2H$.	—	1·70	4·78

Appreciable differences are shown in the first three members only.

When chlorine, bromine, iodine, or cyanogen, is substituted for hydrogen, the acid character increases.

Acid	4 litres	32 litres	256 litres
Monochloracetic CH_2ClCO_2H	6·98	17·3	37·8
Dichloracetic $CHCl_2CO_2H$.	34·8	60·3	76·2
Trichloracetic CCl_3CO_2H .	65·9	75·0	79·1
Monobromacetic CH_2BrCO_2H	—	16·1	36·8
Cyanacetic CH_2CNCO_2H .	10·5	25·3	57·8
α-Bromopropionic $CH_3CHBrCO_2H$	7·87	17·6	36·2
β-Iodopropionic $CH_2ICH_2CO_2H$	1·534	4·385	11·6

The chlorinated acids are seen to increase in strength as the amount of chlorine increases but even trichloracetic acid does not reach the value for hydrochloric acid. The substitution of bromine, or cyanogen, for hydrogen acts in the same way as the substitution of chlorine; the action of cyanogen is much more marked than that of bromine. Introduction of the group OH for H in the fatty acids increases the strength of the acids, although not to so great an extent as is noticed in the preceding table.

Acid	4 litres	32 litres	256 litres
Glycolic CH_2OHCO_2H . . .	2·08	5·77	15·09
Glyoxylic $COH.CO_2H$ . . .	3·65	9·83	24·51
Lactic $CH_3CHOHCO_2H$ . .	1·94	5·49	14·42
β-Oxypropionic $CH_2OHCH_2CO_2H$.	0·896	2·63	7·18
Trichlorolactic $CCl_3CHOHCO_2H$.	11·0	27·7	54·8
Pyruvic CH_3COCO_2H . . .	9·05	22·1	43·8
Glyceric $CH_2OHCHOHCO_2H$.	2·46	6·87	17·9
α-Oxybutyric $C_2H_5CHOHCO_2H$.	1·44	3·99	10·08
β-Oxybutyric $CH_3CHOHCH_2CO_2H$	1·31	3·4	7·70
Oxyisobutyric $(CH_3)_2COHCO_2H$.	1·98	5·07	12·81
Methoxyacetic $CH_2OCH_3CO_2H$.	2·99	8·29	20·75
Ethoxyacetic $CH_2OC_2H_5CO_2H$.	2·40	6·94	17·98
Diglycolic $O(CH_2CO_2H)_2$ . .	5·00	13·78	33·58
Thiodiglycolic $S(CH_2CO_2H)_2$.	—	11·73	28·22

The influence of the relative positions of the OH groups appears to be of importance. In the cases of the isomeric lactic acids and the oxybutyric acids, that one is the strongest in which the OH is nearest the COOH group. Pyruvic and glyceric acids seem to obey the same law. The following members of the oxalic acid series have been investigated:

Acid	4 litres	32 litres	256 litres
Oxalic $(CO_2H)_2$	35·82	61·4	79·8
Malonic $CH_2(CO_2H)_2$ . . .	6·34	16·6	37·7
Succinic $C_2H_4(CO_2H)_2$ . . .	1·30	3·72	10·03
Methylmalonic $CHCH_3(CO_2H)_2$.	—	12·91	30·8
Pyrotartaric $C_2H_3CH_3(CO_2H)_2$.	2·29	5·74	13·19
Dimethylmalonic $C(CH_3)_2(CO_2H)_2$	—	12·14	29·59
Ethylmalonic $CH(C_2H_5)(CO_2H)_2$.	—	15·18	35·06
Suberic $C_6H_{12}(CO_2H)_2$ . . .	—	—	6·99
Sebacic $C_8H_{16}(CO_2H)_2$ . . .	—	—	6·6*
Malic $C_2H_3(OH)(CO_2H)_2$ . . .	2·97	8·63	22·28
Tartaric $C_2H_2(OH)_2(CO_2H)_2$ . .	5·05	13·68	33·15
Racemic $C_2H_2(OH)_2(CO_2H)_2$ . .	5·07	13·64	33·19
Saccharic $C_4H_4(OH)_4(CO_2H)_2$.	—	12·14	29·73
Mucic $C_4H_4(OH)_4(CO_2H)_2$ . .	—	—	16·39

* By extrapolation.

As the distance between the two carboxyls increases the dibasic acids become rapidly weaker; sebacic acid is scarcely stronger than the higher acids of the acetic series. Of the two isomerides, succinic acid and isosuccinic or methylmalonic acid, the latter has the carboxyls nearer together, and is therefore the stronger. Tartaric acid and racemic acid show no difference; hence the latter when in solution is not a compound of right-handed and left-handed tartaric acid, as is the case in the crystalline form, but it is rather a mixture of the two.

The derivatives of benzoic acid are of special interest owing to the conditions under which isomerism occurs in this series. The following have been investigated:—

Acid	32 litres	256 litres
Benzoic $C_6H_5CO_2H$	—	9·95
Oxybenzoic [1:2] $C_6H_4OHCO_2H$	—	33·02
" [1:3] "	4·31	11·24
" [1:4] "	2·39	6·65
Nitrobenzoic [1:2] $C_6H_4NO_2CO_2H$	—	54·34
" [1:3] "	—	20·83
" [1:4] "	—	22·0*
Chlorobenzoic [1:2] $C_6H_4ClCO_2H$	—	32·54
" [1:3] "	—	15·13
" [1:4] "	—	12·7*
Bromobenzoic [1:2] $C_6H_4BrCO_2H$	—	38·89
" [1:3] "	—	14·8

* By extrapolation.

The substituting radicle always exerts most influence on the strength of the acids when it is in the ortho position. There is little difference between the meta and para positions. It is strange that para-oxybenzoic acid should be weaker than benzoic acid itself, as in all other cases the introduction of OH increases the strength of the acid. This points to the conclusion that the affinity-forces are of the nature of vector quantities, that is, that they are directed forces the resultants of which cannot be put as simply equal to the sums of the components. The other acids of the aromatic (or benzenoid) group for which measurements have been made are as follows:—

Acid	32 litres	256 litres
Amidobenzene sulphonic [1:3] $C_6H_4NH_2SO_3H$	4·55	16·13
Amidobenzene sulphonic [1:4] $C_6H_4NH_2SO_3H$	10·84	26·36
Mononitrophenol [1:2] $C_6H_4NO_2OH$	--	1·02
" [1:3] "	0·14	0·26
" [1:4] "	0·177	0·41
Dinitrophenol [1:2, 1:4] $C_6H_3(NO_2)_2OH$	—	10·95
Trinitrophenol [1:3:5] $C_6H_2(NO_2)_3OH$	—	79·7
Anisic $C_6H_4OCH_3CO_2H$	—	5·00
Toluic $C_6H_4CH_3CO_2H$	3·51	9·1
Phenylglycolic $C_6H_5CHOHCO_2H$	9·02	22·75
Phenoxyacetic $C_6H_5OCH_2CO_2H$	12·57	29·85
Phthalic [1:2] $C_6H_4(CO_2H)_2$	15·15	35·23
" [1:3] "	—	20·0
Nitrophthalic $C_6H_3(NO_2)(CO_2H)_2$	38·62	66·57
" "	29·22	57·50 25·00

The introduction of NH_2 into benzene sulphonic acid, which is nearly as strong as hydrochloric acid, is accompanied by the production of a much weaker acid. The meta-acid is weaker than the para-acid. The three nitrophenols show the gradation ortho, para, meta, in the same way as the nitrobenzoic acids. The phenols rapidly increase in strength with the number of NO_2 groups they contain. Another point of interest is the difference exhibited by the isomerides anisic acid, phenylglycolic acid, and phenoxyacetic acid. Orthophthalic acid greatly exceeds metaphthalic acid in strength; while of its two nitro derivatives, the α compound, in which the NO_2 group is adjacent to the carboxyl, proves itself superior to the β derivative, in which there is a greater distance between the NO_2 and the COOH groups. As regards the unsaturated acids, the following numbers show that they are the stronger the less hydrogen they contain.

Acid	4 litres	32 litres	256 litres
Acrylic $C_2H_3CO_2H$	1·25	3·46	9·20
Crotonic $C_3H_5CO_2H$	0·728	2·15	5·88
Fumaric } $C_2H_2CO_2H$	—	13·52	32·5
Maleic } $C_2H_2CO_2H$	17·46	39·15	65·49
Citraconic } $C_3H_4CO_2H$	9·56	24·05	49·67
Itaconic } $C_3H_4CO_2H$	1·92	5·33	14·66
Mesaconic } $C_3H_4CO_2H$	—	11·93	29·45
Hydrocinnammic $C_6H_5C_2H_4CO_2H$	—	2·26	6·08
Cinnammic $C_6H_5C_2H_2CO_2H$	—	—	7·56
Phenylpropiolic $C_6H_5C_2CO_2H$	—	27·66	52·0
Hydrosorbic $C_5H_9CO_2H$	—	2·29	6·29
Sorbic $C_5H_7CO_2H$	—	—	6·70
αBromocinnammic $C_6H_5C_2HBrCO_2H$	—	—	62·70
βBromocinnammic $C_6H_5C_2HBrCO_2H$	—	—	33·1
Meconic $C_5HO_2OH(CO_2H)_3$	—	102·1	141·5
Quinic $C_6H_7(OH)_4CO_2H$	—	7·81	19·92
Camphoric $C_6H_9C_2H_5CO_2H$	—	—	6·07

On comparing acrylic with propionic acid, crotonic with butyric acid, fumaric and maleic with succinic acid, and citraconic, itaconic, and mesaconic with pyrotartaric acid, it is evident that for each withdrawal of H_2 the acid becomes stronger. These relations become very conspicuous when we compare hydrocinnammic with cinnammic and phenylpropiolic acid, and hydrosorbic with sorbic acid. As regards the peculiarities of the dibasic unsaturated acids, they can only be just mentioned. Meconic acid, which stands by itself, is conspicuous by its great strength. It is the strongest of all acids which consist of carbon, oxygen, and hydrogen only, and it approaches very near to sulphuric acid. There is evidently some connexion between this property and the small amount of hydrogen this acid contains.

The introduction of amidogen and similar radicles makes the acids weaker.

Acid	8 litres	32 litres	256 litres
Amidoacetic $CH_2NH_2CO_2H$	0·236	0·257	0·32
Hippuric, $CH_2NH(C_6H_5CO)CO_2H$	—	6·68	17·88
Acetylamidoacetic $CH_2NH(CH_3CO)CO_2H$	—	6·88	17·76
Oxamic $CONH_2CO_2H$	21·07	35·88	62·26
Oxaluric $CO(NHCONH_2)CO_2H$	—	57·03	74·28
Parabanic $(CONH)_2CO$	43·35	48·23	53·96

The introduction of the NH_2 group into acetic acid is attended with a great reduction of the strength of the acid. This acid is considerably less weakened when one of the hydrogens in the NH_2 group is replaced by the negative radicle benzoyl or acetyl. Oxalic acid is also weakened by introducing the NH_2 group. On the other hand the introduction of the urea residue ($NHCONH_2$) into oxalic acid only slightly decreases the conductivity of the oxalic acid. Parabanic acid does not contain the carboxyl group, nor does it behave at all like an acid, since its conductivity increases but slightly with dilution.

The conditions of affinity among acids form the best-known part of the theory of affinity.

Our knowledge concerning the bases is much more scanty. From the fact that the relative affinities of acids are independent of the nature of the bases, we can infer that the relative affinities of the bases must also be independent of the nature of the acids (*J. pr.* [2] 16, 422). It is highly probable that the same laws hold for bases as for acids.

It must, however, be admitted that there is great lack of experimental data in this department. Some experiments of Menschutkin (*C. R.* 96, 256), who drew from them the conclusion that Berthollet's law of the influence of mass does not hold, prove only that under the conditions of the experiment the relative affinities of the bases compared—potash to aniline, to trimethylamine, and to ammonia, in alcoholic solutions—are very different. The same fact was proved by some thermo-chemical experiments of Berthelot.

Nor have many experiments been made by the kinetical method. Warder (*B.* 14, 1361) who first applied this method to bases, measured the velocity of decomposition of ethylic acetate. An investigation made by Reicher (Van't Hoff, *Dyn. chim.* 107) in connexion with Warder's work, showed that the velocity of the reaction is nearly the same for potash, soda, and baryta, the electrical conductivities being also nearly the same.

Ostwald (*J. pr.* [2] 33, 352) has recently investigated the electrical conductivities of some bases. The alkalis KOH, NaOH, LiOH, are strong bases; they have nearly the same conductivities. TlOH acts as an alkali. The conductivities of CaO_2H_2, SrO_2H_2, and BaO_2H_2, referred to masses *equivalent* to NaOH, &c., are the same as those of NaOH, &c.; the *molecular* conductivities of CaO_2H_2, &c., are, however, double those of NaOH, &c. Ammonia is a weak base; its conductivity is much influenced by dilution; the variations in the molecular conductivity follow the same law as was observed for acids. Substitution of H or H_2 in NH_3 by CH_3, C_2H_5, and other alkyl groups, increases the strength of the base; but $N(CH_3)_3$ and $N(C_2H_5)_3$ are weaker bases than $NH(CH_3)_2$ and $NH(C_2H_5)_2$. These bases all follow the same law of dilution. The non-volatile ammonium bases, *e.g.* NMe_4OH—and also the base $(C_2H_5)_3S(OH)_2$—exhibit conductivities nearly the same as those of the alkalis; guanidine is a little weaker, but belongs more to the ammonium bases than to the derivatives of ammonia.

In a memoir not yet published, Ostwald shows that these conclusions are confirmed by kinetical experiments on the saponification of ethylic acetate.

Besides the investigations which have led to numerical values for certain constants of affinity, there are numerous others from which such quantities cannot be deduced, because the reactions investigated were too complex. To this class belong principally the works of Berthelot and P. de St. Gilles on etherification, and the investigations of Menschutkin (collected in *A. Ch.* [5] 30, 31) on the same subject.

The importance of the first of these in chemical dynamics has already been emphasised. The latter have brought out interesting connections between the reactions observed and the chemical constitution of the acids used. The values obtained do not, however, lend themselves to the determination of coefficients of affinity; and the investigations themselves cannot therefore be considered here at greater length. The work of Horstmann (*B.* 12, 64), and of Dixon (*T.* 1884. 617), on incomplete combustion can likewise only be mentioned.

Little attention has as yet been directed to the investigation of the influence of temperature on the velocities of reactions, and on the constants of affinity. For the case of the inversion of cane sugar there are the investigations of Wilhelmy, Urech, and Spohr; for the velocity of etherification there are those of Berthelot and P. de St. Gilles, as well as those of Menschutkin. The whole question has been thoroughly investigated by Van't Hoff. By applying the dynamical theory of heat he finds that the equation for the relation between the temperature and the velocity of the reaction, k, must be of the form

$$\frac{d \log k}{d\tau} = \frac{A}{\tau^2} + B$$

where τ is the absolute temperature, and A and B are constants.

Van't Hoff has also shown that for several reactions the observed facts can be very well represented by such a formula. For details the book of Van't Hoff which has been mentioned must be consulted.

Berthelot and P. de St. Gilles have found that the chemical equilibrium of etherification is independent of the temperature within a wide range. Ostwald established the same generalisation for the relative affinities of various acids. Van't Hoff shows by the help of the dynamical theory of heat that this will occur when the reactions producing equilibrium do not give an appreciable thermal effect as their resultant. Moreover, when this is not the case, with a fall of temperature the equilibrium shifts in favour of that reaction which produces more heat than the reverse one (*l. c.* 167).

We have now arrived at the point where we must take up the problem concerning the relation between affinity and production of heat. As soon as it had been recognised that the thermal action accompanying a chemical reaction was the measure of the chemical *energy* used up therein, an attempt was made to apply this to the question of affinity.

In 1854, J. Thomsen enunciated the following laws (*P.* 92, 34). The magnitude of the force evolved in the formation of a compound is equal to the quantity of heat produced. When a compound is decomposed by another body the reason for this is that the stronger affinities satisfy themselves; hence decomposition must be accompanied by an evolution of force. Since chemical force when liberated under ordinary conditions generally manifests itself as an evolution of heat, it follows that '*every simple or complex effect of a purely chemical nature is accompanied by production of heat.*'

This deduction, plausible though it seems at first sight, is not correct. Heat does not measure forces but quantities of energy; hence the chemical production of heat does not tell us anything concerning the intensity of chemical forces: it is only the product of their (mean) value (if we imagine them to be forces of attraction) into the space passed over by the atoms that is a quantity of energy, and as such is measurable by thermal methods. Since we know nothing about the spaces passed over by the atoms, and, moreover, cannot assume that the spaces are the same for all compounds, no conclusion regarding the chemical forces can be accurately drawn from measurements of the quantities of heat produced in chemical reactions.

To point out the old mistake would have been uncalled for, were it not that Berthelot has of late years enunciated an analogous erroneous 'law,' which he has defended with great warmth. It is the more necessary to submit this theory to criticism, as, owing to the great prestige which the renovator of this old mistake enjoys—a prestige he owes to his excellent experimental researches—the theory is surrounded as it were by a halo which has deterred many from closely examining it. Berthelot formulates his law as follows: '*Tout changement chimique accompli sans l'intervention d'une énergie étrangère tend vers la production du corps, ou du système de corps, qui dégage le plus de chaleur.*' And further: '*Toute réaction chimique susceptible d'être accomplie sans le concours d'un travail préliminaire et en dehors de l'intervention d'une énergie étrangère à celle des corps présents dans le système, se produit nécessairement, si elle dégage de la chaleur.*'

By a vague connexion with general dynamics, Berthelot calls this *the principle of maximum work.* He assumes it to follow as a natural consequence from the dynamical theory of heat. This view is erroneous. There is no such thing as a law according to which a dynamical system is in equilibrium when the greatest possible quantity of its potential energy has been changed into actual energy; but this would be the dynamical analogue of the so-called chemical law.

There does, however, exist a law in the dynamical theory of heat according to which a system is in equilibrium when it has attained to the maximum *entropy*. This function, which was first introduced by Clausius, is, like the energy of a system, entirely dependent on the condition of the system; it is defined by the equation, $dS = \frac{dQ}{T}$, where S stands for entropy, Q for a quantity of heat given to the body, and T for the absolute temperature. Horstmann (*A.* 170, 192), was the first to apply this law to chemical phenomena. The investigation has also been carried out very fully by Willard Gibbs. Unfortunately, the law is of very limited application. The integration can only be accomplished if the substances experimented with are perfect gases: Horstmann has shown that the law of entropy then leads to the same result as is attained by applying Guldberg and Waage's law of the influence of mass. This law has thus been supplied from the theoretical side with a valuable confirmation.

As far as we can tell, the law of entropy does not generally lead to reactions which are quite completed on one side, but rather to conditions of chemical equilibrium between opposite processes. According to Van't Hoff (*l.c.* p. 153), these processes vary with the temperature, if they are accompanied by a positive or negative production of heat, and the law is that the equilibrium shifts the more in favour of the positive thermal production the lower is the temperature. It is, however, only at absolute zero that the reaction would take place in one direction only (if at this temperature chemical reactions are at all possible); and it is only for this limiting case that a law of maximum thermal effect would hold good.

This is all that the law of the maximum thermal effect really contains; it is a limiting case from which the actual conditions differ the more the higher is the temperature. Since the temperature at which ordinary chemical reactions occur is not very high, the reactions accompanied by production of heat preponderate. This had been already noticed by Thomsen, and the approximation to truth contained in the law we certainly owe to him.

What Berthelot has added refers to the cases of chemical equilibrium which have been established beyond doubt, and which, according to the principle of maximum work, ought not to occur; this law asserts that because one of two reciprocal reactions is attended with production of heat that one ought to take place exclusively. It is Berthelot's endeavour to reduce all reactions in which chemical equilibrium has been observed to cases of partial *dissociation*, wherein the masses of the reacting bodies do not act as wholes. To accomplish this, he is obliged to call reactions of a purely chemical nature, dissociations; for example, the decomposition of acid sodium sulphate in aqueous solution, a reaction brought about by the affinity between sulphuric acid and water. The whole explanation resolves itself into reasoning in a circle. It need scarcely be said that an explanation of this kind cannot account for the laws by which the chemical equilibrium, the velocity of chemical reactions, and the electrical conductivities of the reacting bodies, are connected.

There is no doubt that, with the possibility of a more general application of the laws of entropy to chemical reactions, thermochemical data will become important and fundamental means for the investigation of the relations of affinity. Moreover, there is little doubt that Bergmann's theory of affinity, revived in a thermochemical form, is not the solution of the problem, and that, in spite of its modern appearance, it can as little keep its ground against Berthollet's far-reaching views as it could in its older form.

Of all the great old-standing problems of chemistry, that of chemical affinity has been least developed. The general relations and laws given in this article refer only to a limited number of substances, and to a limited number of reactions; many parts of the question have not yet been investigated at all. Great and important progress has, however, been achieved by Berthollet's enunciation, and Guldberg and Waage's rational formulation of the law of active masses. It must, however, be admitted that there are some reactions which seem to contradict this law, and which cannot be explained by it when taken in its simple form. It is not necessary to reject the law on this account, as has been done by some. The actual conditions of each experiment we make are so complex that we are not able to completely apply the law of the influence of mass. We must content ourselves with an approximation which does not always lie within the limits of experimental errors. The motions of the stars cannot yet be represented in strict accordance with the law of gravitation; yet the first approximation is sufficient to remove any doubts as to the validity of the law. The law of the influence of mass in its simple application is also only true to a sufficient approximation in those cases in which the effects considered are of great magnitude as compared with those neglected. (In connexion with *affinity* v. Physical methods; section *Optical.*) W. O.

AGAR-AGAR or *Bengal Isinglass.*

A vegetable gum obtained in China from seaweeds: *Eucheuma spinosum*, *sphærococcus lichenoides*, *spinosus*, and *tenax*. Transparent colourless strips, almost completely soluble in water: forms a large quantity of thick, tasteless, and odourless jelly. Dilute H_2SO_4 forms galactose, characterised by its conversion into galactonic acid by Br_2 and Ag_2O. This galactose is formed from a carbohydrate, $C_6H_{10}O_5$, present in the agar-agar (Bauer, *J. pr.* [2] 30, 367).

AGARICIC ACID

$C_{16}H_{30}O_5$aq. [139°] (J.); [145·7°] (F.). S. ·8 at 15°. Obtained, together with agaric resin, from the larch-fungus (*Boletus Laricis*) by extraction with dry ether (Fleury, *C. R.* 70, 53) or with 90 p.c. alcohol (Jahns, *Ar. Ph.* [3] 21, 221, 260).

Four-sided, silvery plates (from 90 p.c. alcohol at 50°) or prisms (from dry alcohol). V. sol. hot glacial HOAc or oil of turpentine, m. sol. chloroform or ether, v. sl. sol. benzene or cold water. Swells up and dissolves in boiling water but crystallises out again on cooling. Oxidised by HNO_3 to butyric and succinic acids.

Salts.—Amorphous, insoluble pps. The neutral salts, $M_2C_{16}H_{28}O_5$ lose H_2O at 120° becoming $M_2C_{16}H_{26}O_4$.—NH_4HA''.—Na_2A'' (at 120°).—K_2A''.—BaA''.—Ag_2A'': gelatinous pp. Hot alcoholic solutions give, with $AgNO_3$, a pp. of $Ag_2C_{16}H_{26}O_4$ (Jahns).

AGARICIN. The fly-agaric (*Agaricus albus*) yields to alcohol a non-nitrogenous crystalline powder having a sweet taste with bitter pungent after taste; slightly soluble in water, insoluble in ether; decomposed by boiling with dilute acids, or by contact with saliva, yielding a substance which exerts a slight reducing power on alkaline copper-solution (Schoonbroodt, *J.* 1864, 613). According to Jahns (*J.* 1883, 1400) it is identical with agaricic acid. H. W.

AGARIC RESIN v. Agaricic Acid.

Red, amorphous, solid; melts at 89·7°; dissolves in absolute alcohol, ether, wood-spirit, and chloroform, but is insoluble in water, benzene, and CS_2; slightly bitter; dissolves in alkalis. Na salt precipitated by alcohol in flocks changing in 24 hours into long needles. Forms precipitates, mostly crystalline with metallic salts (Fleury, *C. R.* 70, 53). H. W.

AGARICUS. A genus of *Fungi.* Many fungi, especially the agarics, contain an amount of nitrogen exceeding that in peas and beans, varying from 3·19 p.c. to 7·26 p.c. (Schlossberger a. Döpping, *A.* 52, 106).

The solid tissue consists of cellulose. Agarics contain mannite and fermentable sugar, but no starch. Many agarics contain fumaric acid, sometimes associated with malic or citric acid.

Agaricus bulbosus and *A. integer* yield crystallisable hydrochlorides and platinochlorides of basic bodies (Thörner).

Agaricus ruber or *sanguineus* contains a colouring-matter, ruberine, soluble in water and in alcohol. It is rose-red by transmitted light, having two absorption bands in the green, but it exhibits strong blue fluorescence. Dilute HCl extracts an alkaloid, agarythrine, from the fungus; this alkaloid is converted by oxidising agents into a red substance, possibly ruberine (T. L. Phipson, *C. N.* 46, 199).

Agaricus integer, contains an acid, with following properties: white needles [70°], very soluble in ether, benzene, CS_2, $CHCl_3$, hot alcohol and acetic acid, insoluble in water, and cold alcohol and acetic acid.—A'_2Pb: insoluble white pp. [114°]. The alkaline salts are sparingly soluble in cold water, and the salts of the heavy metals, insoluble (Thörner, *B.* 12, 1635).

Agaricus atramentosus yields to boiling ether a dioxyquinone $C_{11}H_6O_2(OH)_2$. Dark brown metallic-shining laminæ, dissolving with yellow colour in alkalis, insoluble in water, ether, light petroleum, benzene, chloroform and CS_2. Sublimes with great difficulty in yellow microscopic tablets. It is reduced by boiling its alcoholic solution with zinc-dust, the resulting colourless liquid becoming yellow-green again on exposure to the air. The *ammonium salt* is a green crystalline powder, dissolving readily in water with violet colour, nearly insoluble in boiling absolute alcohol.—Ba *salt*: dingy flesh-coloured crystalline precipitate (Thörner, *B.* 11, 533). The *diacetyl derivative* $C_{15}H_{12}O_4 = C_{11}H_6O_2(OAc)_2$ forms small reddish yellow tablets.

Boletus Laricis contains besides agaricic acid and (25 p.c. of) agaric resin also 3 to 5 p.c. of a neutral body, which crystallises in needles, [272°], and may be sublimed (E. Jahns, *J.* 1883, 1400). H. W.

AGAVE. Well preserved juice of *Agave americana*, sp. gr. 1·046 at 15° was found by J. Boussingault (*A. Ch.* [4] 11, 447) to contain in 1000 parts: 26·45 levulose, 61·71 saccharose, 3·53 malic acid, 5·45 gum, 10·13 albumin, 0·06 ammonia, 6·21, inorganic salts, and 886·46 water. H. W.

AGE or **AXIN.** The fat of *Coccus Axin* growing in Mexico, consists of the glycerides of lauric and axinic acids (Hoppe, *J.* 1860, 324). H. W.

AGGREGATION, STATES OF.—In this article the differences between the properties of bodies in the solid, the liquid, and the gaseous, condition, are looked upon as due to differences in the state of aggregation of those small particles, of which, according to the molecular theory of the constitution of matter, all bodies are composed. According to this theory, our power of subdividing matter cannot be carried beyond a certain limit, whatever means—chemical, physical, or mechanical—we employ. In other words, the theory asserts that the largest quantity of a body which we cannot subdivide by any means in our power is of finite size; it is called the atom of the substance of which the body is composed. Each elementary body has its peculiar atom, and the union of atoms of different kinds forms the smallest quantity which can exist of a compound substance; this, however, cannot, in accordance with the definition, be called an atom, since, by the nature of the case, it can be divided by chemical, and often even by physical, means. Though matter can be divided down into atoms by chemical means, yet we have reason to believe that when only physical processes are going on the sub-division of matter is not in general carried so far; and that just as in an army, though the unit is the individual soldier, yet for military purposes the soldiers forming a regiment always act together, so in matter, groups of atoms, called molecules, remain together for a considerable time. The molecule, however, is a very much less definite thing than the atom, and it must not be assumed without proof in each case that the term has always a definite meaning, or that there may not in the same body be molecules consisting of very different numbers of atoms. There is strong evidence, too, that, in some cases at any rate, the molecule does not always consist of the same atoms; the molecule after a time seems to break up and the constituent atoms find fresh partners. In some cases, however, such as those of the permanent gases, we have reason to believe that the number of molecules which consist of the same number—say N—of atoms, is enormously greater than the number of those consisting of any other number of atoms. If, however, we raise the temperature, then, in the case of some gases at any rate, dissociation sets in; that is, there are now a considerable number of molecules in which the number of atoms is less than N; this is shown by the abnormally small densities of such gases at high temperatures. On the other hand, the density of a vapour near its point of condensation is often abnormally great, as in the case of acetic, formic, and monochloracetic, acid; a part at any rate of this increase in density would seem to be due to the formation of molecules consisting of a greater number of atoms than those formed when the temperature was raised far above that of the point of condensation.

According to the molecular theory of matter, the difference between the molecular constitution of bodies in the solid, liquid, and gaseous, state is that in the solid state the molecules oscillate about a position of equilibrium and never get far from their original position in the body; in the liquid state the molecules are supposed not to oscillate about positions of equilibrium, but to be comparatively free to move in any direction; they cannot, however, move far without coming under the influence of other molecules, so that their courses are constantly being changed and do not bear any approximation to straight lines; in the gaseous state the molecules are so far apart that for the greater part of the time they are describing straight lines, the time during which they are under the influence of other molecules being an exceedingly small fraction of the whole time.

We must be careful to remember that there is no evidence that the molecules in the liquid or solid state consist of the same number of atoms as those of the same substance in the gaseous state; but that on the contrary it seems most probable that in the solid and liquid states the molecules are systems whose complexity is not only very different from the molecules in the gaseous state but that these molecular aggregations vary very much in complexity among themselves. These molecular aggregations are probably not permanent but are continually breaking up and their constituents changing partners; this breaking up and re-formation of the molecular aggregations would produce the same effect as the collisions between the molecules of a gas, that is, it would tend to equalise the distribution of momentum and energy, so that it would make the substance possess viscosity, and be able to conduct heat. In fact, the collision between two molecules of a gas is the formation and breaking up of a molecular aggregation, and the difference between this case and that of a solid or a liquid is that the ratio of the time the molecular aggregation lasts to the time which elapses between the formation of successive aggregations is much smaller in the case of the gas than in that of the liquid or solid. The simplest state of aggregation we can imagine is one where the molecule and the atom are identical, that is, where the molecule consists of only one atom; this case is realised by a monatomic gas such as mercury, and possibly by all gases when the temperature is sufficiently high. The properties of matter in this state have not been investigated with special regard to the differences between this and more complex states of aggregation; Schuster (*Pr.* 1885), however, has shown that the phenomena of the electric discharge through mercury vapour are quite different from those occurring in a gas whose molecules are polyatomic.

In the case of most elementary gases the molecules consist generally of two atoms, and this case has received by far the largest amount of attention both from the experimental and the theoretical point of view. The most important results of the kinetic theory of gases from the chemical point of view are:—first, Avogadro's law, which states that in equal volumes of all gases at the same temperature and pressure there are the same numbers of molecules. From this it follows at once that, as long as all the molecules consist of the same number of atoms, the ratio of the molecular weights of two gases is the same as the ratio of their densities. It must, however, be clearly understood that this result is only true for perfect gases, that is, for gases in which the pressure is produced entirely by the striking of the molecules against the sides of the vessel containing the gas, and not at all by the force between the molecules. If a gas obeys Boyle's law it is a perfect gas for this purpose, and we may apply Avogadro's law to it; this law is not, however, applicable when Boyle's law does not hold. If the departure from the law be slight, and if δp be the deviation of pressure from that given by Boyle's law, then the number of molecules in unit volume will equal the number in the same volume of a perfect gas at the same temperature and pressure multiplied by $\left\{1-\frac{\delta p}{p}\right\}$, where p is the pressure. This correction is quite appreciable in the case of all but the most permanent gases. Maxwell investigated the distribution of velocity among the molecules of a gas, and showed that when the gas was in a steady state the molecules could not all be moving with the same velocity; he gave (*P.M.* [4] 19, 22) a formula which tells how many molecules there are whose velocities are between any assigned limits. We shall here, however, only give a few numbers calculated from that formula. To take the case of oxygen at 0°C., about ½ the molecules are moving with velocities of between 300 and 600 metres per second, about ¼ between 300 and 100, only about $\frac{1}{100}$ with velocities less than 100 metres per second, and not $\frac{1}{1000}$ part with velocities greater than 1,200 metres per second. The velocities with which the molecules of the same gas are moving at different temperatures are proportional to the square roots of the absolute temperatures; thus the distribution of velocity among the molecules of oxygen at 273°C. would be got by multiplying by $\sqrt{2}$ all the velocities at 0°C. The velocities with which the molecules of different gases are moving at the same temperature are inversely proportional to the square roots of their molecular weights; thus, for example, the velocities of the hydrogen molecules are on a scale four times as great as that of the oxygen molecules.

We can estimate by the methods of the kinetic theory of gases (see Meyer, *Die Kinetische Theorie der Gase*) the number of molecules in a cubic centimetre of the gas, and the diameter of the molecule, if the molecule is looked on as a hard elastic sphere; or if the molecule be considered as a system, we can estimate the distance between two molecules when their paths become appreciably curved. We find as the result of such calculations that there are about 21 trillion molecules in a cubic centimetre of gas under the pressure of 760 mm. of mercury at 0°C; so that the mean distance between the molecules is between 3 and 4 millionths of a millimetre, or about $3{\cdot}5 \times 10^{-7}$ centimetres; the diameter of the molecule is probably between 1×10^{-7} centimetres and 3×10^{-9} centimetres, or between ¼ and $\frac{1}{100}$ of the mean distance between the molecules. Another quantity which it is important to know is the mean distance through which the molecule passes between two collisions; this is called the mean free path of the molecule, and it is inversely proportional to the density. For hydrogen at the pressure of 760 mm. of mercury the mean free path is about $1{\cdot}8 \times 10^{-5}$ centimetres; at the pressure of 1 mm. the free path is about $\frac{1}{11}$ of a millimetre; and at a pressure of a millionth of an atmosphere about 18 centimetres. When the free path is comparable with the dimensions of the vessel in which the gas is inclosed, the gas can exhibit phenomena of a different character from those shown when the free path is indefinitely small compared with the dimensions of the vessel. The radiometer exhibits effects of this kind, and Crookes has called a gas rarefied so much as to show rotation in a radiometer, matter in the fourth or ultra gaseous state. But this is using the word *state* in a different sense from that in which it is used in the phrases solid, liquid, and gaseous, states; for these states do not depend upon anything but the matter itself, while the ultra-gaseous state depends upon the ratio of the free path to the other lengths involved; if we increased all the lengths proportionately to the rarefaction, the gas would not show any of those properties which characterise the so-called ultra-gaseous state, while, on the other hand, if we experimented with small enough instruments we could get all the ultra-gaseous effects manifested by a gas at the atmospheric pressure.

The distribution of energy among the molecules is of much chemical interest. It seems, however, that in one respect the results of theory have been misinterpreted; it has been said that because iodine, for example, is dissociated at a temperature a little over 600°, and since in iodine at any temperature there are some molecules possessing the same amount of energy as those which are split up at 600°, that therefore these molecules ought to be split up, and if any substance were present capable of combining with free iodine the whole of the iodine would ultimately combine with this substance. Now although there are apparently no experiments which may be called secular to say whether or not this would ultimately happen, yet it is certain that it does not happen so quickly as theory would indicate, if every molecule which possessed the same kinetic energy as that possessed by the average molecule at 600° were straightway dissociated and entered into combination with the other substances present; there seems, however, to be no reason why this should be the case, for though one molecule at 0° may have the same energy as one at 600°, yet dissociation must depend upon the surrounding molecules as well as upon the molecule itself. Now the molecule at 600°, though it possesses at any instant the same energy as one at 0°, is yet surrounded by molecules which are moving very much faster than itself, and whose energy is much more nearly equal to its own, so that it is not so likely to lose its energy by collision with other molecules as the molecule at 0° which is surrounded by molecules with much less energy than itself. For this reason the tendency to dissociate will be very much greater at 600° than at 0°, and a molecule at the former temperature may dissociate while the latter may lose its energy before this can happen.

The distribution of energy affects the specific heat very much; so that if we know the value of the specific heat we can tell a good deal about the energy of the molecule, as the following theoretical investigation will show. Let us begin with the case of a gas the molecule of which is of any degree of complexity, measured by the number of degrees of freedom, p. There is a theorem due to Boltzmann which states that the mean energy corresponding to each degree of freedom is the same, so that the mean total energy of the molecule is $\frac{p}{3}$ times the mean energy due to the translatory motion of the centre of gravity. Though there is very strong evidence against the truth of the theorem in this form, and the mathematical proof of it is unsatisfactory, yet a very special case of it is probably true, viz. that if we have a molecule consisting of n atoms approximately symmetrically arranged (that is, if the distance between a particular pair of atoms is not always very much less than the distances between the other pairs), then the ratio of the mean total kinetic energy of the molecule to the energy due to the translatory motion of its centre of gravity is proportional to n, the number of atoms in the molecule.

Let the ratio of the total kinetic energy to the translatory energy of the centre of gravity, which by the kinetic theory of gases is measured by θ the absolute temperature, be βn. Then the total kinetic energy in the gas $= \Sigma\beta n\theta = \beta N'\theta$, when N' is the number of atoms in the gas. If all the atoms be of the same mass, m, and the quantity of gas be the unit of mass, then $N'm = 1$, so that the total kinetic energy in the gas $= \frac{\beta\theta}{m}$, which, if β be the same for all elementary gases, is inversely proportional to the atomic weight of the gas. If the gas had been a compound such that each molecule consisted of a atoms of mass m, b of mass m', c of mass m'', and so on, then for unit mass of the gas,

$$\frac{N'(ma + m'b + m''c)}{(a + b + c)} = 1,$$

so that the energy in unit mass

$$= N'\beta\theta$$

$$= \frac{\beta\theta(a + b + c)}{ma + m'b + m''c}.$$

Now $a + b + c$ is the number of atoms in the molecule, and $ma + m'b + m''c$ is the mass of a molecule, so that the energy of unit mass

$$= \frac{\beta\theta(\text{number of atoms in the molecule})}{\text{mass of the molecule.}}$$

Let us first suppose that all the energy in the gas is kinetic, then the energy in unit mass of the gas at temperature θ is $\frac{\beta\theta}{m,}$ so that the specific heat is $\frac{\beta\theta}{m,}$ or the product of specific heat into the mass of an atom, which is called the atomic heat, is equal to β, and, as experiment shows, does not vary much from gas to gas. For a compound, we see from the expression given above for the energy, that the product of the specific heat into the mass of a molecule equals β(number of atoms in the molecule), so that for all perfect gases, simple or compound, the product of the specific heat into the mass of the molecule $= \beta$(number of atoms in the molecule). We may remark that with our assumptions the ratio of the specific heat at constant pressure to that at constant volume

$$= 1 + \frac{2}{3\beta}\left(1 + \frac{\delta p}{p}\right)\frac{1}{\text{number of atoms in the molecule}},$$

when δp is the deviation of the pressure from that given by Boyle's law. The experimental results show that for most perfect gases, simple or compound, the molecular heats are constant, showing that β is constant for such gases, or that the whole kinetic energy is proportional to the product of the number of atoms in the molecule and the energy due to the translatory motion of the centre of gravity. There are, however, some simple gases, such as chlorine and bromine vapour, whose atomic heats are much higher than the value given by the above rule. These gases are, however, easily liquefied, and so when heat is applied, work is done in altering the molecular state as well as in raising the temperature; this will produce an effect equivalent to increasing β, and will therefore explain the large value of the atomic heat. We should expect a large value for this quantity too if the gas were dissociating. There are some compound gases, on the other hand, such as ammonia, ethylene, and marsh gas, whose molecular heats are too small to agree with the above rule, if we suppose that the number of different systems in the molecule is the same as the number of atoms indicated by the chemical formula of the gas. If, however, two or more atoms always remain close together, they will for our purpose count as one atom, as it is only when the molecules are approximately symmetrically arranged that we can assume that the total energy is proportional to the number of atoms. The total energy is proportional to the number of distinct systems; and if a group of atoms always remain close together they only count as one system, however many atoms there may be. If, for example, the atoms in a radicle always remain together, the radicle, for this purpose and in the formula for the ratio of the specific heats, will only count as one atom. We may therefore regard those compounds which have too small atomic heats, as consisting of but few separate systems, though there may be a great number of atoms in the molecule.

The determinations by Dulong and Petit and others of the specific heats of elementary bodies in the solid state show that for these bodies the atomic heat is approximately constant, while Kopp's experiments on the specific heats of compound solid bodies show that for many such solids the product of the mol. w. and the specific heat is proportional to the number of atoms in the molecule, just as for gases. The expression for the kinetic energy of unit mass of a solid will probably be of the same form as that which we found for a gas; for this only depends upon the assumptions that the absolute temperature is proportional to the mean energy due to the translatory motion of the centre of gravity of the molecules, and that the ratio of the mean total kinetic energy of the molecule to the mean energy due to the translatory motion of the centre of gravity is proportional to the number of atoms in the molecule. These assumptions will probably hold for the solid and liquid as well as for the gaseous state. We must remember that when heat is applied to a solid or liquid, work is done in altering the molecular configuration as well as in increasing the kinetic energy of the molecules. All solids and liquids appear to be able to get into a condition in which the specific heat does not alter with the temperature, and it is in this condition that the atomic heat is constant. Now if the specific heat is independent of the temperature, the work spent in altering the molecular configuration must bear a constant ratio to the work spent in increasing the kinetic energy; and if the atomic heat is constant this ratio must be the same for all substances; so that Dulong and Petit's experiments show that when heat is applied to a solid or liquid it is divided between the energy of molecular configuration and the mean kinetic energy, in the same proportion for all substances; and since for many substances, such as iodine, bromine, mercury, &c., the specific heat in the solid state is twice that in the gaseous, it is equally divided between these two forms of energy, a result which purely dynamical considerations would also lead us to regard as the most probable one. The specific heats of liquids seem to be more irregular than those of either solids or gases, but the bodies for which this is the case are those whose melting and boiling points are comparatively close together, and we may suppose that the nature of the molecular configuration alters with each change in temperature, and this makes the specific heat abnormally large. The specific heats of those substances which exist in the fluid state through wide ranges of temperature seem to be the same in the solid and fluid states.

When the specific heat of a solid compound is much smaller than the number of atoms in it would lead us to expect, we may, just as in the case of a gas, conclude that two or more atoms always remain close together in the molecule. It is important to notice, however, that the specific heat cannot give us any information about what we may call the molecular aggregation of the solid or liquid, that is it affords no information as to whether the molecules are isolated or form groups, for if we suppose the molecules to unite and form more complex ones the atomic heat would remain the same as long as the energy was equally divided among the atoms or radicles forming the molecules.

Change of State.—Gaseous to Liquid.

By the application of great pressure accompanied when necessary by intense cold, all gases have been liquefied, and during this process they pass through all intermediate states, so that at some stage of the process it is impossible to tell whether the substance is a gas or a liquid. It is found that there is for each gas a temperature above which it cannot be liquefied by the application of the most intense pressure, so that at a temperature higher than this the substance can only exist as a gas. This temperature is called the critical temperature, and Andrews has proposed to call a substance at a temperature higher than its critical temperature a gas, and one which though in a gaseous condition is yet at a temperature lower than the critical temperature, a vapour. Van der Waals (*Continuität des Gasformigen und flüssigen Zustandes*, 87), and Clausius (*W.* 9, 1880), have shown how to calculate the critical temperature from the difference between the pressure of the gas in any state and that given by Boyle's law.

We shall here confine ourselves to showing, by general reasoning, that a critical temperature must exist. When a body is in the liquid state the ratio of the work required to separate the particles to an infinite distance to the kinetic energy of the molecules must exceed a certain limit, for the substance will behave as a liquid or a gas according as the forces between the molecules are or are not able to change their kinetic energy appreciably in the interval from one collision to another. The molecules will change their kinetic energy appreciably if the ratio of the alteration in the mutual potential energy of the molecules to their initial kinetic energy is finite, but for this to be the case the ratio of the work required to separate the molecules to an infinite distance must be finite, so for a body to be in the liquid condition this ratio must exceed a certain quantity, say, R. Let V be the work required to separate one of the molecules from the remainder, and T the kinetic energy of the translatory motion which is proportional to the absolute temperature; then the substance will behave like a liquid if $\frac{V}{T}$ be greater than R, but like a gas if $\frac{V}{T}$ be less than this quantity. Now V cannot be greater than the work, V', required to separate the molecules when they are quite close together, so that when $T > \frac{V'}{R}$ the substance will always behave like a gas. Now T is proportional to the absolute temperature, so that when the absolute temperature exceeds a certain value the substance will always behave like a gas, that is, it cannot be liquefied. This shows that there must be a 'critical temperature,' and it also shows that the critical temperature is proportional to the work required to separate the molecules; a measure of this will be the amount of heat required to convert the substance from a liquid into a gaseous state under infinite pressure. We can take as a practical measure the latent heat of the substance. The mean kinetic energy of the translatory motion equals the absolute temperature, so that if h be the latent heat, θ the critical temperature, NV' will be proportional to h, where N is the number of molecules in unit mass, and T is proportional to θ, so that since $\frac{V'}{T}$ is constant, we should expect to find that the critical temperature multiplied by the number of molecules in unit mass—or, what is proportional to it, the reciprocal of the molecular weight—ought to be related to the latent heat so that when one is great the other is great also. The following table will show that this condition is approximately fulfilled:—

Substance	Absolute critical temperature	Critical temperature divided by mol. w.	Latent heat
Alcohol C_2H_6O . .	510	11·1	209
Acetone C_3H_6O . .	505	8·7	140
Carbon disulphide CS_2 .	546	7·3	105
Benzene C_6H_6 . .	558	7·17	109
Methyl acetate $C_3H_6O_2$.	503	6·8	110
Ethyl formate $C_3H_6O_2$.	503	6·8	105
Sulphurous oxide SO_2 .	429	6·7	94
Ether $C_4H_{10}O$ . .	468	6·3	94
Ethyl acetate $C_4H\,O_2$.	513	5·83	105
Chloroform $CHCl_3$.	533	4·51	67
Carbon tetrachloride CCl_4	557	3·6	52

Passage from the Liquid to the Gaseous State.

Though it requires the application of pressure and cold to make a substance pass from the gaseous to the liquid state, yet the substance will always to a limited extent pass of itself from the liquid into the gaseous state. In the space over a liquid in the equilibrium condition there is always a quantity of the vapour of the liquid, the quantity of vapour in unit volume depending only on the nature of the liquid and the temperature; in other words, the vapour exerts a definite pressure called the vapour pressure (often erroneously the vapour tension). If we have a quantity of liquid in a vessel furnished with a piston the liquid will evaporate until there is a certain quantity of vapour in each unit of volume above the liquid; if we depress the piston so that this volume diminishes by v then a quantity of vapour equal to that in volume v will condense; if the piston be raised again the vapour will be re-formed. In this way we can have a continual transference from the gaseous into the liquid state and back again. In this process, however, we have only matter in these two states and have no continuity of state from the gaseous to the liquid as we had in the process by which the permanent gases are liquefied. The vapour pressures of different liquids vary enormously; thus for sulphuric acid the vapour pressure is so small as to be almost inappreciable; for sulphuric acid, mixed with its own volume of water, it is about one-eighth of a mm. at 15°C.; for water at the same temperature it is about 12·6 mm.; for alcohol, 32 mm. The vapour pressure always increases as the temperature rises, but until the temperature reaches a certain value depending on the pressure, the liquid which evaporates is always that on the surface, and none of the liquid in the interior passes into the gaseous condition. When, however, the vapour pressure becomes greater than the pressure on the surface of the liquid, the bubbles of vapour which form on the sides will be at a pressure equal to or greater than the pressure in the surrounding fluid, and so will expand and be able to reach the top without condensing. When this takes place, *i.e.* when portions of the liquid not on the surface are converted into gas, the liquid is said to boil. The temperature of the boiling-point will increase with the pressure; it cannot, however, even by the application of an infinite pressure, be raised above the critical temperature of the substance. Bodies which have small vapour pressures at ordinary temperatures have high boiling-points; but it does not follow that because the vapour pressure of one substance is at some temperature greater than that of another its boiling-point will be lower; for example, at 15°C. the vapour pressure of carbon tetrachloride is greater than that of methyl alcohol, though its boiling point is higher. According to the molecular theory, some of the molecules manage to escape from the liquid, we may suppose because they are moving so fast as to be able to escape from the attraction of the other molecules; on the other hand, some of the molecules of the vapour strike the surface and get caught by the molecules of liquid. When things are in a state of equilibrium as many molecules escape from the liquid as are caught by it.

Although the vapour densities of many substances have been determined, few experiments seem to have been made on the rate of evaporation and condensation. The knowledge of these rates would very much increase our knowledge of the constitution of fluids.

The forces between the molecules in the liquid state must be sensible, otherwise we should not be able to spend work upon a liquid without increasing the kinetic energy, as we do when we convert water into steam at the same temperature. The latent heat may be taken as a measure of the potential energy lost by the transition from the gaseous to the liquid state. In a fluid the potential energy of the molecular configuration seems to depend only on the mean distance between the molecules; for the fluid resists anything tending to diminish its volume, but does not resist anything tending to change its shape. When the fluid is in such a condition that its specific heat is independent of the temperature then any increase in the kinetic energy must be accompanied by a proportionate increase in the potential energy of the molecular configuration. Now, if the forces between the molecules are large it will require a smaller increase in the distance between them to increase the potential energy by a given amount than if they were smaller; so that for a given increase in the kinetic energy, that is, a given rise in temperature, the increase in volume will be less when the forces between the molecules are great than when they are small, so that the coefficient of expansion will be small when the forces between the molecules are great, but when the forces between the molecules are great the fluid is incompressible and the product of the mol. w. and latent heat is large; so that we should expect a small coefficient of expansion, incompressibility, and large latent heat for equal volumes to go together, and we find by the following tables of these quantities that this seems to be the case.

Substance	Product of latent heat and mol. w.	Coefficient of expansion	Compressibility
Water, H_2O	11,088	·000065	4·51
Benzene, C_6H_6 . . .	8,502	·00138	
Acetone, C_3H_6O . . .	8,120	·00172	
Chloroform, $CHCl_3$ . .	7,906	·00140	
Carbon tetrachloride, CCl_4	7,904	·00140	
Ether $(C_2H_5)_2O$ . . .	6,956	·0021	10·8
Carbon bisulphide, CS_2 .	6,840	·00146	6·26

A peculiarity of water is that it is denser at 4°C. under atmospheric pressure than at any other temperature under the same pressure; we may perhaps suppose that this is due to something of the following kind. We know that when water freezes it expands and crystallises in the hexagonal system; now we may suppose that, before the water solidifies, molecular aggregations are formed which possess the same property as is possessed by the ice crystals, viz. that when the molecules are arranged in this way they occupy a greater volume than when arranged uniformly—the formation of these aggregations would tend to increase the volume and might be sufficient to more than counterbalance the diminution due to the nearer approach of those particles which do not form these aggregations.

CHANGE OF STATE FROM SOLID TO LIQUID.

When the temperature of a solid is raised sufficiently high it begins to melt. There are two kinds of melting; in the one, as in the case of ice, if the heat is applied slowly the temperature remains constant until all the substance has passed from the solid into the liquid state In this case there is a definite melting-point. In the other case, of which an example is the melting of sealing-wax, the substance first begins to soften, then as more heat is applied it gets softer and softer, its temperature, however, increasing until when a certain temperature is reached the substance is liquid; in this case there is no definite melting-point, as the process is spread over a considerable range of temperature. This would seem to imply that the substances which melt in the second way are not perfectly homogeneous in structure, but contain molecular aggregations of various degrees of complexity, which get gradually split up as the temperature rises; while those substances which melt like ice have a more uniform constitution, so that any change of state takes place simultaneously through the molecules. This would obviously tend to make the transition more definite. This view is in accordance with the fact that crystalline bodies, which are generally regarded as being more uniform in structure than non-crystalline, all melt in the same way as ice. Sealing-wax in the state of transition is what is called a viscous body; so that on this view a viscous substance is regarded as a mixture of molecules some of which are in the same state as they are when the substance is liquid, and some are in the same state as they are when the substance is solid. A dynamical illustration will enable us to see how such a body might behave like a rigid body under the action of rapidly changing forces, and like a fluid under constant or slowly varying forces. Suppose we have a series of heavy spheres connected by strong springs placed upon a horizontal table, and that one end of this row of spheres is fastened to a peg which cannot sustain a tension greater than T without breaking; then if a steady pull, T, be exerted at the other end of the row of spheres the string will break, but if the tension at the end, instead of being steady, be periodic, and if the period of vibration be greater than the natural period of vibration of the spheres and springs, then if the number of spheres be great enough the string will not break, though a tension enormously greater than T is acting at the other end. This is quite a parallel case to that of the viscous fluid; the springs and spheres correspond to those molecules which are in the same condition as when the substance is solid, the string to those in the fluid condition.

The change of state from solid to liquid seems to be always accompanied by a change in volume, and when this is so the melting-point —as J. Thomson proved—must be altered by the application of pressure. Thomson showed that this followed from thermodynamical considerations; and that when the substance expanded on solidification, like ice, the melting-point was lowered by pressure, but when the substance contracted on solidification the melting-point was raised by pressure. The most important substances which expand on solidification are water, bismuth, antimony, and cast-iron; none of these crystallises in the regular system, so that we may suppose that the molecules are arranged unsymmetrically, that while some are nearer together than when in the liquid state, others are further apart, producing on the whole an increase of volume.

The specific heat of a body in the solid condition is in general less than when it is in the liquid, except for those substances whose melting and boiling-points are very far apart, when it seems to be about the same in the two states; if we know the specific heat of a substance in both the fluid and the solid state at all temperatures, we can find the amount of heat necessary to convert unit mass of the substance from the solid to the liquid state. For Clausius has proved that if λ be the latent heat at the temperature t, s_1 and s_2 the specific heats in the solid and liquid states respectively at the same temperature, then

$$\frac{d\lambda}{dt}+s_2-s_1=\frac{\lambda}{t}.$$

A similar equation will apply to the change from the liquid to the gaseous state. Some bodies, such as camphor and iodine, sublime, that is pass directly from the solid to the gaseous state, and as these bodies exhibit a definite vapour-pressure—they must also pass directly from the gaseous into the solid states.

In the solid and liquid states the molecule is probably a very much more complex thing than the gaseous molecule, it is probably also not nearly so definite. Maxwell, in the article 'Atom' in the *Encyclopædia Britannica*, shows how the hypothesis of groups of molecules of different degrees of stability would explain the residual effects of elasticity, and states that in his view a solid consists of groups of molecules, some of which are in different circumstances from others. J. J. T.

AGONIADIN $C_{10}H_{14}O_6$. A crystalline bitter substance occurring in Agoniada bark (from *Plumeria longifolia*), which is used in Brazil as a remedy for intermittent fever. Needles, very bitter, v. sl. sol. ether, v. sol. hot alcohol, and CS_2. Nearly insoluble in cold, easily soluble in boiling water. When boiled with sulphuric acid it yields a sugar (Peckolt, *Ar. Ph.* [2] 144, 34).
H. W.

ALACREATINE $C_4H_9N_3O_2$ *i. e.* $NH_2.C(NH).NH.CHMe.CO_2H$ *α-guanido-propionic acid.* S. 8·3 at 15°. Formed by mixing conc. solutions of alanine and cyanamide, adding a little NH_3, and allowing the mixture to stand (Baumann, *A.* 167, 83). Small prisms, v. sl. sol. cold alcohol. At 180° it changes into its anhydride, alacreatinine. Boiling baryta-water forms alanine and urea, or its decomposition-products, CO_2 and NH_3. HgO oxidises it, forming guanidine.

Methyl-alacreatine $NH_2.C(NH).NMe.CHMe.CO_2H$. From α-methyl-amido-propionic acid, cyanamide, and a little NH_3 (Lindenberg, *J. Pr.* [2] 12, 253). Monoclinic prisms, sl. sol. cold water or alcohol.

ALACREATININE $C_4H_7N_3O$ aq. Formed by dehydration of alacreatine by the action of heat or dilute acids, crystallises from water in long prisms, which give off aq in dry air or at 100°. M. sol. alcohol, more soluble in water than alacreatine. With zinc chloride it forms crystalline scales $(C_4H_7N_3O)_2ZnCl_2$, S. 4·35 at 20°, v. sl. sol. alcohol (Baumann, *B.* 6, 1371).

ALANINE $C_3H_7NO_2$, *i.e.* $CH_3.CH(NH_2)CO_2H$ *a-amido-propionic acid.* Mol. w. 89. S. 2·2 at 17°; S. (cold alcohol of 80 p.c.) ·2.

Formation.—1. From ethylic *a*-chloropropionate and ammonia (Kolbe, *A.* 113, 220; Strecker, *A.* 75, 29).—2. From *a*-bromopropionic acid and alcoholic ammonia (Kekulé, *A.* 130, 18).

Preparation.—An aqueous solution of 2 pts. aldehyde-ammonia is mixed with aqueous hydrocyanic acid containing 2 pts. HCy; hydrochloric acid is added in excess; the mixture is evaporated to dryness over a water-bath; the residue is digested with a mixture of alcohol and ether, which leaves NH_4Cl undissolved (Strecker).

Properties.—Tufts of colourless needles or oblique rhombic prisms, having a nacreous lustre. Sublimes at 200°. V. sl. sol. cold alcohol, insol. ether. The aqueous solution has a sweet taste, does not affect vegetable colours and gives no precipitates with any of the ordinary reagents. Alanine is isomeric with urethane, lactamide, and sarcosine; distinguished from the two former by not melting below 100°, and from the last by its solubility in water and its behaviour to metallic oxides.

Reactions.—1. Not altered by boiling with dilute *acids* or with *alkalis*.—2. Fused with KOH, it gives off hydrogen and ammonia and forms cyanide and acetate of potassium.—3. Resolved by boiling its aqueous solution with PbO_2, into aldehyde, carbon dioxide, and ammonia; $C_3H_7NO_2 + O = C_2H_4O + CO_2 + NH_3$.—4. Decomposed in aqueous solution by *nitrous acid*, with evolution of nitrogen and formation of lactic acid. H. W.

ALANT CAMPHOR $C_{10}H_{16}O$. Occurs in elecampane root, and is obtained together with solid alantic anhydride by distilling with water. Liquid smelling like peppermint, boiling at 200°. Heated with P_2O_5, it yields a hydrocarbon $C_{10}H_{14}$ which boils at 175°, and is converted by oxidisation with chromic acid into terephthalic acid (Kallen). H. W.

ALANTIC ACID $C_{15}H_{22}O_3$ [91°].—Obtained from its anhydride (*v. sup.*). Slender needles (from alcohol). Dissolves sparingly in cold, more readily in boiling water, very easily in alcohol. The *barium salt* forms warty masses moderately soluble in water. The *silver salt* $AgC_{15}H_{21}O_3$ forms small scales having a silvery lustre (Kallen, *B.* 9, 155).

Alantic Anhydride $C_{15}H_{20}O_2$ [66°], (275°), crystallises from dilute alcohol in prismatic needles. Easily sublimable. Dissolves very sparingly in water, very easily in alcohol, ether, &c.—The *chloride* $C_{15}H_{21}O_2Cl$ [140°] formed by passing HCl-gas into a solution of alantic acid in absolute alcohol, crystallises in large rhombic tablets, melting, with evolution of HCl, at 140°. It unites with bases, forming salts which readily decompose, with separation of metallic chlorides. By excess of caustic alkali it is converted into dialantic acid, $C_{30}H_{42}O_5$ (?) —The *amide* $C_{15}H_{21}O_2.NH_2$ [210°], obtained by passing ammonia-gas into an alcoholic solution of the anhydride, forms small crystals, melting, with decomposition at 210°, slightly soluble in alcohol, resolved by potash into ammonia and alantic acid. H. W.

ALBUMEN *v.* Proteïds.

ALCAMINES *v.* Alkamines.

ALCOGEL. A gelatinous compound of silicic acid with alcohol (*q. v.*).

ALCOHOL C_2H_6O or EtOH (*ethyl alcohol, aqua vitæ*). Mol. w. 46. (78·2°) at 762·7 mm. (R. Schiff); (78·3°) (Regnault); (78·4°) at 760 mm. (Kopp, *A.* 92, 9); (78·5°) (Perkin); (12·8°) at 20·9 mm.; (21°) at 41·3 mm. (Kahlbaum, *B.* 16, 2480). S.G. $\frac{15}{4}$ ·79367 (S.); $\frac{15}{15}$ ·79503 (P.); $\frac{25}{25}$ ·78820 (P.); $\frac{20}{4}$ ·8000 (Brühl). S.V. 62·18 (S.); 62·7 (Ramsay). V.D. 1·613 (for 1·591, Gay-Lussac). S.H. ·615 (Kopp); ·659 (20° to 78°) (Reis); ·6019 (16°–20°); ·6067 (16°–35°); ·6120 (16°–40·5°) (J. H. Schüller, *P. Ergbd.* 5, 116, 192). H. F. p. 58,470. H. F. v. 57,020 (*Th.* iv. 229). μ_{β} 1·3667 R_{∞} 20·31 (B.). M.M. 2·78 (P.).

Name.—The term *alcohol* was used in the time of Libavius (1595) to denote a powder. Spirit dried over powdered potassic carbonate was called *spiritus alcolisatus.* Kopp (*Geschichte*, iv. 281) suggests that this term does not mean spirit that has been treated with the powder, but that it is a corruption of *spiritus alcalisatus*, or spirit that has been treated with alkali. Alcolised or alcoholised spirit was then shortened to alcohol.

Occurrence.—1. In fermented saccharine juices.—2. In putrid, and even in healthy, tissues, such as ox-brain (Béchamp, *C. R.* 89, 573).—3. In crude coal-tar benzene (about 2 parts per million) (O. N. Witt, *C. C.* 1878, 416).—4. In the fruits and juices of some living plants (Gutzeit, *A.* 177, 344).—5. In bread (Bolas, *C. N.* 27, 271).—6. In crude wood-spirit (V. Hemilian, *B.* 8, 661).—7. Together with acetone, in the urine of diabetic patients (Markownikoff, *B.* 9, 1441, 1603).

Formation.—1. By the decomposition of glucose under the influence of ferments (*v.* Fermentation): $C_6H_{12}O_6 = 2C_2H_6O + 2CO_2$. Levulose, maltose, and melitose also give alcohol on fermentation.—2. From olefiant gas by dissolving it in conc. H_2SO_4, diluting and distilling (Hennel, *P. M.* 1826, 240; Berthelot, *A. Ch.* [3] 43, 385): $C_2H_4 + H_2SO_4 = C_2H_5SO_4H$

$$C_2H_5SO_4H + H_2O = C_2H_5OH + HSO_4H.$$

The absorption of ethylene is greatly facilitated by heating the H_2SO_4 to 100° or, better still, 170° (Goriainow a. Butlerow, A. 169, 147).—3. By reduction of acetic anhydride (Linnemann, *A.* 148, 249), acetyl chloride (Saytzeff, *J. pr.* [2] 3, 76), or aldehyde, by means of sodium-amalgam.—4. By heating ether at 170° with water slightly acidulated with H_2SO_4 (Erlenmeyer a. Tscheppe, *Z.* [2] 4, 343).

Preparation.—When aqueous solutions of grape-sugar are fermented by yeast, 95 p.c. of the sugar splits up into alcohol and carbonic acid, but 4 p.c. goes to form succinic acid and glycerin, while 1 p.c. is used by the yeast as food. Small quantities of *n*-propyl, iso-butyl, and the two iso-amyl alcohols, $Me_2CH.CH_2.CH_2OH$ and $MeEtCH.CH_2OH$, are also formed. The mixture of these four alcohols is known as fusel oil. According to Rabuteau (*C. R.* 87, 500), potato spirit contains also iso-propyl, *n*-butyl, and secondary amyl alcohols.

The liquid to be fermented must contain nitrogenous matter and some inorganic salts to serve as food for the yeast; grape-juice, or a mixture of water with germinating barley (malt), to which a mash of potatoes may be added, are the liquids usually employed. Diastase, an unorganised ferment in malt, converts the starch of the potatoes into a sugar, maltose, which then undergoes alcoholic fermentation.

When any of these alcoholic liquids are distilled the first portions of the distillate are rich in alcohol. By repeated rectification 'rectified spirit' containing 91 p.c. of alcohol may be got. Fusel oil may be removed by adding to the spirit about ·7 of its weight of coarsely powdered charcoal, leaving the mixture to stand for several days, and stirring repeatedly, then decanting and distilling. Animal or blood charcoal may also be used.

Absolute Alcohol.—The last traces of water may be removed by repeated rectification over freshly heated K_2CO_3, CaO, BaO, $CuSO_4$, or $CaCl_2$. The best way is to digest strong spirit with quick lime at 40° for two hours, and then, on distilling, to reject the first and last portions (Mendeléeff, *Z.* 1865, 260). If the spirit contain more than 5 p.c. of water a second treatment with lime will be necessary (Erlenmeyer, *A.* 160, 249). If dry baryta be used to complete the drying, as soon as the alcohol is absolute it will become yellow, dissolving a little BaO (Berthelot, *J.* 1862, 392).

References.—C. Bullock, *Ph.* [3] 4, 891; J. L. Smith, *Am. Ch.*, 5 120; Dittmar a. Stewart, *C. N.* 33, 53; Friedel a. Crafts, *A. Ch.* [4] 9, 5.

Properties.—A transparent, colourless, mobile, liquid. It has a characteristic odour and burning taste. When undiluted it acts as an inflammatory poison. It solidifies at −130·5° (Wroblewsky a. Olszewsky, *M.* 4, 338). Very hygroscopic. Miscible with water. Burns with a pale flame. Snow (1 pt.) mixed with alcohol (2 pts.) produces a freezing mixture (−20°, *Bn.* 1, 237).

Alcohol dissolves fats, oils, resins, alkaloids and most organic substances. It dissolves $CaCl_2$ and $SrCl_2$ but not $BaCl_2$; $Ca(NO_3)_2$ but not $Sr(NO_3)_2$ and $Ba(NO_3)_2$; LiCl but not KCl and NaCl. It does not dissolve carbonates or sulphates. It dissolves I, Br, P, and S.

The critical point of alcohol is 234·6° at 48,900 mm. At this point 1 g. occupies 3·5 c.c. (Ramsay a. Young, *Pr.* 38, 329). Alcohol vapour in contact with liquid acquires its normal density, 23, at 50° (R. a. Y.).

When alcohol is mixed with water contraction takes place and heat is evolved. The maximum contraction occurs when 49·8 vols. water and 53·9 vols. alcohol at 0° produce 100 vols. of mixture instead of 103·7 vols. This corresponds to a possible compound, EtOH 3aq (Mendeléeff, *Z.* 1865, 262).

The greatest difference between the observed specific heats of solutions of alcohol and the values calculated on the assumption of mere mixture occurs in a solution containing about 80 p.c. of alcohol by weight, corresponding to the formula EtOH 6aq. The greatest difference between the observed and calculated boiling-points and between observed and calculated capillarity also occurs in the same mixture, but the maximum deviation from calculated (or mean) compressibility is exhibited by a solution containing 40 p.c. of alcohol by weight (Dupré a. Page, *Pr.* 17, 333; *P. M.* [4] 38, 158). The maximum rate of transpiration through capillary tubes is exhibited by the solution EtOH 3aq (Graham, *A.* 123, 102).

Detection of Water in Alcohol.—1. $CuSO_4$ ought not to turn blue (Cassoria).—2. Benzene ought not to form a cloudiness, due to water-drops (Gorgeu, *C. R.* 30, 691).—3. Wet alcohol produces a pp. of BaO when added to a solution of BaO in absolute alcohol (Berthelot, *A. Ch.* [3] 46, 180).—4. If alcohol be added to a mixture of anthraquinone (·001 g.) with a little sodium amalgam, a green coloration indicates absence of water, otherwise a red colour is produced (Claus, *B.* 10, 927).

The following table gives the percentages of absolute alcohol, determined by Tralles:

Volumes per cent.	Weights per cent.	Specific gravity at 15·56°	Volumes per cent.	Weights per cent.	Specific gravity at 15·56°
0	0	1·0000	51	43·47	·9315
1	0·80	·9976	52	44·42	·9295

33	0·9528	67	0·8793		

Proof spirit was a term originally intended to denote spirit that was just strong enough to ignite gunpowder when burnt upon it, but it was defined by law in the reign of George III. to be spirit 'such as shall at the temperature of 51° F. weigh exactly twelve-thirteenth parts of an equal amount of distilled water.' It has, therefore, S.G. ·920 at 15·6° C., and contains 49·24 pts. alcohol to 50·76 pts. water by weight, or 100 vols. alcohol to 81·82 vols. water.

Alcoholic Drinks.—*Beer* contains from 2 to 6 p.c. of alcohol; *hock* and *claret* from 8 to 10 p.c.; *port* and *sherry* from 15 to 20 p.c.; *gin*, *rum*, and *whisky* from 51 to 54 p.c.

Detection.—1. The liquid supposed to contain alcohol is repeatedly rectified, after drying with K_2CO_3. The alcohol is recognised by its boiling-point, and by converting it into ethyl iodide, and noting the boiling-point of the iodide (72°).—2. The suspected liquid is distilled and some of the distillate (8 c.c.) mixed with water (10 c.c.) and H_2SO_4 (5 c.c.); some $KMnO_4Aq$, and after five minutes a solution of magenta, bleached by SO_2, are added. A red colour indicates that aldehyde had been formed by the oxidation of the alcohol. Acetone, formic acid and methyl alcohol do not show this reaction, so that it may be used to detect ethyl alcohol in wood spirit. Other primary alcohols behave more or less like ethyl alcohol (Riche a. Bardy, *C. R.* 82, 768).—3. An aqueous solution of alcohol warmed with KOH and iodine deposits iodoform. This 'iodoform reaction' is given also by aldehyde, acetone, *n*-propyl, *n*-butyl, sec. butyl, and octyl alcohols, by propionic and butyric aldehydes, by lactic, quinic, and meconic acids, by acetophenone, methylic butyrate, acetic ether, and oil of turpentine.

The 'iodoform reaction' is not given by methyl and amyl alcohols, by formic, acetic, butyric, valeric, oxalic, succinic, malic, tartaric, racemic, citric, pyrotartaric, suberic, sebacic, uric, mucic, isethionic, benzoic, salicylic, anisic, cinnamic, and picric acids, phenol, valeric aldehyde, benzoic aldehyde, glycol, glycerin, mannite, glycocoll, leucine, chloral, ethyl chloride, ethylene chloride and bromide, chloroform, tetrachloride of carbon, sulphide of carbon, toluene, and ether (Lieben, *A. Suppl.* 7, 226). Sugar and dextrin give a small amount of iodoform.

The formation of ethyl acetate and benzoate is also recommended as a test for alcohol.

Estimation.—The liquid is distilled and the S.G. of the distillate taken.

Detection of Fusel Oil.—1. The liquid is diluted with water until it contains about 12 p.c. alcohol; it is then shaken with chloroform. This extracts the amyl alcohol, which it leaves behind on evaporation; by warming with KOAc and H_2SO_4 this is converted into amyl acetate, smelling like pear-drops.—2. The alcohol is diluted until it forms a 50 p.c. solution. 100 c.c. are then shaken with 20 c.c. chloroform at 15° in a graduated cylinder. If the chloroform layer is 37·1 c.c. the alcohol is free from higher homologues, but if it occupy a larger volume, fusel oil is present. Thus 39·1 c.c. indicates 1 p.c. amyl alcohol (Röse, *B.* 19, R. 184).—3. The height to which the alcohol will rise in capillary tubes of known diameter is observed.

Pure alcohol rises higher than alcohol adulterated with fusel oil (J. Traube, *B.* 19, 892).

Reactions.—1. *Potassium* and *sodium* act upon alcohol, evolving hydrogen and forming EtOK and EtONa respectively.—2. *Phosphorus trichloride* forms EtCl, HCl, ethyl phosphite, and phosphorous acid (Béchamp, *C. R.* 40, 944): $6EtOH + 2PCl_3 = 3EtCl + 3HCl + Et_3PO_3 + H_3PO_3$ A smaller quantity of PCl_3 acts in the cold thus: $PCl_3 + HOEt = PCl_2(OEt) + HCl$ (Menschutkin, *A.* 139, 343).—3. PCl_5 reacts thus:

$$EtOH + PCl_5 = EtCl + ClH + PCl_3O.$$

4. P_2S_5 produces mercaptan:

$$5EtOH + P_2S_5 = 5EtSH + P_2O_5.$$

5. Alcohol coagulates *albumen*, and, partly on this account and partly by arresting the development of low organisms, it prevents the putrefaction of dead animal matter.—6. Vapour of alcohol passed through a *red hot tube* produces CO_2, water, hydrogen, CH_4, C_2H_4, naphthalene, and charcoal. If the tube be filled with pumice, benzene, phenol, and perhaps also aldehyde and acetic acid, are also formed (Berthelot, *A. Ch.* [3] 33, 295; *A.* 81, 108).—7. *Zinc dust* at 300°–350° forms ethylene and hydrogen: $C_2H_6O + Zn = ZnO + C_2H_4 + H_2$. Alcohol-vapour passed over zinc dust at a dull red heat forms CO, CH_4, and H_2 (Jahn, *M.* 1, 378).—8. Alcohol scarcely conducts an *electric current*, but when acidulated with 5 p.c. H_2SO_4 the current passes, hydrogen comes off at one pole and, at the other, aldehyde, ethyl formate sulphate and acetate, together with small quantities of acetal, and $CH_3.CH(OH)(OEt)$ are formed (Renard, *A. Ch.* [5] 17, 295). Alcohol containing a little potash produces hydrogen at the negative pole and aldehyde-resin at the positive pole (Connell).—9. Alcohol burns with a pale flame forming CO_2 and H_2O. Alcohol vapour undergoes rapid, but incomplete, combustion when mixed with air and exposed to finely divided *platinum*; acetic acid, aldehyde, formic acid, acetal, and acetic ether are formed. Hence a coil of red hot platinum wire will keep red hot if placed round the wick of a spirit lamp that is not burning (glow-lamp of Sir H. Davy).—10. Finely divided *rhodium*, *iridium*, and *ruthenium*, in presence of an alkali, decompose alcohol, with elimination of H and formation of an acetate (Deville a. Debray, *C. R.* 78, 1782).—11. *Oxygen* does not attack cold pure alcohol, but *ozone* forms acetic and formic acids (Boillot, *C. R.* 76, 1132).—12. *Chromic acid* mixture oxidises alcohol to aldehyde and acetic acid.—13. An *ammoniacal solution of* CuO at 180° attacks alcohol, forming acetic acid and Cu_2O (A. Letellier, *C. R.* 89, 1105).—14. $KMnO_4$ in acid, but not in alkaline, solution forms aldehyde and acetic acid (Chapman a. Smith, *C. J.* 20, 301). 15. Strong *nitric acid* acts violently, giving off copious red fumes containing nitrous ether, nitric oxide, CO_2, aldehyde, acetic and formic acids. If the action be moderated by making three layers of fuming HNO_3, water, and alcohol, and allowing them to mix slowly by diffusion, the following bodies are formed: aldehyde, acetic acid, glyoxal, glyoxylic acid, glycollic acid, and oxalic acid (Debus).—16. In presence of *urea*, *nitric acid* converts alcohol into ethyl nitrate (*q. v.*).—17. In presence of *mercuric nitrate*, *nitric acid* acts upon alcohol with production of fulminate of mercury (*q. v.*); in a similar way fulminate of silver may be made.

If mercury (1 pt.) be dissolved in HNO_3 (12 pts.) (S.G. 1·3) and the liquid left for some days till no more nitrous fumes appear and the liquid is colourless, and then alcohol (12 pts. of S.G. ·8) be added and the mixture be warmed, a pp. is produced which is not mercuric fulminate. It may be crystallised from diluted (4 vols.) HNO_3 (1 vol.). It is $C_2H_2Hg_3O_2(NO_3)_2$. At 120°-130° it explodes. It is insoluble in water, alcohol, and ether. *Potash* converts it into $C_2H_2Hg_3O_2(OH)_2$; while cold $K_2C_2O_4$ slowly converts it into the oxalate, $C_2H_2Hg_3O_2C_2O_4$, a body which is browned by sunlight. A mixture of HNO_3 and alcohol converts it into mercuric fulminate (Cowper, *C. J.* 39, 242; *v.* Gerhardt, *A.* 80, 101).—18. *Chlorine* is rapidly absorbed by alcohol, and in sunlight the liquid may even take fire. The ultimate product is chloral alcoholate, $CCl_3.CH(OEt)(OH)$, but this is probably the result of a long series of reactions (v. Chloral). Besides chloral, there are formed HCl, aldehyde, acetal, acetic acid, EtCl and other chlorinated bodies.—19. *Bromine* forms HBr, water, EtBr, bromal, and bromal alcoholate (E. Hardy, *C. R.* 79, 806).—20. Dry *chlorine* passed into alcohol mixed with $K_2Cr_2O_7$ gives aldehyde, EtCl, acetyl chloride, and EtOAc (Godefroy, *Bl.* [2] 40, 168).—21. When alcohol is distilled with much water and *bleaching powder*, chloroform (*q. v.*) is formed. When bleaching powder (300 grms.) is mixed with absolute alcohol (67 grms.) in 10 minutes the mixture gets hot and alcohol distils over together with a green oil, which explodes when exposed to sunlight or heated, and among the products of the explosion are mono- and di-chloro-acetal (Schmitt a. Goldberg, *J. pr.* [2] 19, 393), aldehyde, and small quantities of chloroform (Goldberg, *J. pr.* [2] 24, 97).—22. *Hydric chloride* produces ethyl chloride:

$$EtOH + HCl = EtCl + H_2O.$$

But when excess of alcohol is used and the solution heated in a sealed tube at 240°, ether is also formed: $EtOH + ClEt = Et_2O + HCl$ (Reynoso, *A. Ch.* [3] 48, 385).—23. *Sulphuric acid* mixes with alcohol with evolution of heat and formation of hydrogen ethyl sulphate:

$$EtOH + H_2SO_4 = EtHSO_4 + H_2O.$$

About half the alcohol and H_2SO_4 take part in the reaction; when more dilute acid is used hydrogen ethyl sulphate is not formed until heat is applied. If a mixture of alcohol with an equal volume (or less) of H_2SO_4 be heated, a further reaction sets in at 120°-150°, ether and water distilling over; this is due to action of alcohol upon hydrogen ethyl sulphate (Williamson, *C. J.* 4, 106, 229; *v.* Ether):

$$HEtSO_4 + EtOH = H_2SO_4 + EtOEt$$

When alcohol is heated with twice its volume (or more) of H_2SO_4 the mixture begins to blacken between 160°-180°, and then gives off ethylene, mixed with SO_2, acetic acid, acetic ether, CO_2, CO, ethyl sulphate, and formic acid. The main reaction is expressed by the equation $C_2H_6O = C_2H_4 + H_2O$ (compare Erlenmeyer, *A.* 162, 373).—24. Anhydrous *sulphuric acid*, SO_3, dissolves in alcohol forming di-ethyl sulphate, Et_2SO_4. Vapour of SO_3 passed into dry alcohol forms crystals of ethionic anhydride,

$C_2H_4{<}\substack{SO_2\\SO_2}{>}O$, or 'carbyl sulphate,' together with ethionic, isethionic, and sulphuric acids, and $HEtSO_4$.—25. Heated with *sulphurous acid* at 200° it forms $HEtSO_4$, ether, H_2SO_4, mercaptan, and S (Pagliani, *J.* 1878, 518).—26. $ClSO_3H$ forms $EtHSO_4$ and other bodies (Baumstark, *A.* 140, 75).—27. When alcohol is dropped upon hot *zinc chloride* the greater part is decomposed in accordance with the equation:

$$2C_2H_6O = C_2H_4O + H_2 + C_2H_4 + H_2O.$$

Hydrogen, ethane, HCl, and polymerides of aldehyde are also formed (W. H. Greene, *C. R.* 86, 1140). When wet alcohol is heated with $ZnCl_2$ at 155°, ether is formed, as well as EtCl, basic zinc chloride being left.—28. *Phosphoric acid* mixed with alcohol forms some di-hydrogen ethyl phosphate, EtH_2PO_4. Alcohol heated with P_2O_5 forms HEt_2PO_4 and Et_3PO_4 (Carius, *A.* 137, 121).—29. Alcohol heated with B_2O_3 forms $EtBO_2$ and Et_3BO_3.—30. *Phosphorus sulpho-chloride*, $PSCl_3$, forms di-hydrogen ethyl thio-phosphate (Chevrier, *Z.* [2] 5, 413):

$$PSCl_3 + 3HOEt = PS(OH)_2(OEt) + 2EtCl + HCl.$$

31. *Chloride of sulphur*, S_2Cl_2, acts upon alcohol forming ethyl chloride, ethyl sulphite, and a small quality of mercaptan (Carius, *A.* 106, 316).—32. *Chloride of antimony* dissolves in alcohol; if the solution be heated to 150° the following reaction ensues (H. Schiff, *A. Suppl.* 5, 218):

$$SbCl_3 + 4EtOH = SbOCl + 2EtCl + Et_2O + 2H_2O.$$

33. Heated with *carbon tetrabromide* at 100° for 12 hours, bromoform is produced (Bolas a. Groves, *C. J.* [2] 9, 784): $CBr_4 + C_2H_6O = CHBr_3 + C_2H_4O + HBr$. Alcohol here acts as a reducing agent, as it does also in the next reaction.—34. Heated with a *di-azo salt*, nitrogen is evolved and the entire di-azo group displaced by hydrogen:

$$C_6H_5.N_2Cl + C_2H_6O = C_6H_5H + N_2 + HCl + C_2H_4O.$$

In some cases the di-azo group is displaced by ethoxyl.—35. Heated with *ammoniacal zinc chloride* at 260°, alcohol is converted into a mixture of mono-, di-, and tri-ethylamine; the yield of mixed bases amounts to 45 p.c. of the alcohol used (Merz a. Gasiorowski, *B.* 17, 637).—36. *Zinc acetate* heated with excess of alcohol at 100° is converted, in about 30 hours, into zinc ethyl acetate and zinc oxide (Kraut, *A.* 156, 323). 37. When *stannic chloride* is distilled with alcohol, ether and EtCl pass over at 140°-170°; afterwards a compound of EtCl with $SnCl_4$ (Kuhlmann, *A.* 33, 106, 192).—38. Crystallised *stannous chloride* distilled with alcohol yields ether, but no EtCl (Marchand); the same decomposition takes place in a sealed tube at 240°. Crystallised *chloride of manganese*, and *ferrous chloride* also etherify alcohol completely at 240°; the *chlorides of cadmium, nickel*, and *cobalt* partially (Reynoso, *A. Ch.* [2] 48, 385).—39. *Platinic chloride* (1 pt.) dissolved in alcohol (40 pts.) of S.G. ·82 and distilled to $\frac{1}{4}$, yields aldehyde, ethyl chloride, HCl, and the solution contains the so-called inflammable chloride of platinum $C_2H_4PtCl_2$, which is left as a sticky mass when the liquid is evaporated (Zeise, *P.* 9, 632; 21, 498; 40, 249).—40. *Platinous chloride* boiled with alcohol forms a black explosive powder called *detonating platinum deposit*, C_2H_4PtO(?) (Zeise, *loc. cit.*).—41. *Mercuric chloride* is slowly reduced to calomel by alcohol.—42. Alcohol heated with *soda-lime*, air being excluded, is converted into sodic acetate, with evolution of hydrogen; at a higher temperature the sodic acetate breaks up into sodic carbonate and marsh-gas.—43. *Chloride of cyanogen* is readily absorbed by alcohol but does not decompose it immediately. After a few days, or more quickly at 60°, NH_4Cl separates, and the liquid then contains ethyl chloride, ethyl carbamate (or urethane), and ethyl carbonate (Wurtz, *A.* 79, 280).

Combinations.—Alcohol combines with many salts, acting like water of crystallisation.—$SbCl_3EtOH$ [67°] needles (from alcohol); resolved by heat into HCl, EtCl, Sb_2O_3, and $SbCl_3$. Soluble in ether and chloroform, but decomposed by water (W. C. Williams, *C. J.* 30, 463).—$AsCl_3EtOH$ (148°): liquid; fumes in the air; decomposed by water (Luynes, *A.* 116, 368).—$CaCl_24EtOH$: got by cooling an alcoholic solution of $CaCl_2$ with ice.—$CaCl_23EtOH$: got by evaporation of such solution over H_2SO_4 (Heindl, *M.* 2, 207).—LiCl4EtOH (Simon, *J. pr.* [2] 20, 376).—$MgCl_26EtOH$ (S.).—$Mg(NO_3)_26EtOH$ (Chodnew, *A.* 71, 256): a crystalline mass deposited from boiling solution.—$PtCl_42EtOH$ (Schützenberger, *J.* 1870, 388).—$SnCl_42EtOH$: crystals formed by evaporation over H_2SO_4 (Lewy, *C. R.* 21, 371; Robiquet, *J. Ph.* [3] 26, 161); heated with acids, this compound readily forms ethyl salts.—$TiCl_4EtOH$ [105°-110°] crystals; decomposed by water (Demarçay, *B.* 8, 75).

Alcoholates or Ethylates are formed by displacing the typical hydrogen by metals. They are decomposed by water:

$$MOEt + H_2O = HOEt + MOH.$$

Aluminium ethylate $Al(OEt)_3$ [130°] S.G.^{4} 1·147. Aluminium does not attack alcohol, but if iodine be present and the liquid be warmed, hydrogen is evolved and aluminium ethylate is formed (Gladstone a. Tribe, *Pr.* 30, 546): $2Al + 6HOEt = Al_2(OEt)_6 + 3H_2$. The reaction probably takes place in three stages:

$$3HOEt + Al_2I_6 = Al_2I_3(OEt)_3 + 3HI$$
$$Al_2(OEt)_3I_3 + 3HOEt = Al_2(OEt)_6 + 3HI$$
$$Al_2 + 6HI = Al_2I_6 + 3H_2.$$

Aluminium (4 g.), iodine (2 g.), and alcohol (40 c.c.), are heated in a flask with inverted condenser; when no more H comes off, the contents are distilled *in vacuo* at 300°. (Good yield (12 g.). G. a. T., *C. J.* 39, 2). When aluminium ethylate has been fused it remains liquid for a long time even at 70°. It is decomposed by water thus:

$$Al_2(OEt)_6 + 6H_2O = Al_2(OH)_6 + 6HOEt.$$

When distilled under atmospheric pressure it decomposes: $Al_2(OEt)_6 = Al_2O_3 + 3C_2H_4 + 3HOEt$, (G. a. T., *C. J.* 41, 5).

Barium ethylate $Ba(OEt)_2Aq$ (Berthelot, *A. Ch.* [3] 46, 180), $Ba(OEt)_2Ba(OH)_2$ (Destrem, *A. Ch.* [5] 27, 8, 22; *C. R.* 90, 1213). A granular pp. formed by boiling an alcoholic solution of BaO, or by heating alcohol with BaO in a digester at 150°. A white powder, turned yellow by oxidation. Converted by CO_2 into baric ethyl-carbonate. Destructive distillation gives C_2H_4, methane, H, and $BaCO_3$.

Calcium ethylate $Ca(OEt)_2$ resembles the barium compound.

Ferric ethylate *$Fe_2(OEt)_6$ (?).—When the proper quantity of sodic ethylate is added to an alcoholic solution of Fe_2Cl_6, all the chlorine is ppd. as NaCl, and the filtrate leaves, after evaporation, a black pasty mass, sol. alcohol, MeOH, ether, benzene, chloroform, or benzoline (Grimaux, *C. R.* 98, 105). A solution of ferric ethylate poured into water produces a solution of colloidal ferric hydroxide.

Potassium ethylate KOEt.—Similar in character to sodic ethylate.

Sodic ethylate NaOEt.—When sodium is dissolved in dry alcohol, H is evolved, and ultimately crystalline laminæ of NaOEt 2HOEt separate. If the solution be evaporated *in vacuo* at 20° needles of NaOEt 3HOEt are got (Forcrand, *Bl.* 40, 177). The alcohol of crystallisation may be driven off at 180°.

Reactions.—1. When mixed with *water* and distilled, alcohol passes over and NaOH is left.—2. Converted by EtI into ether (Williamson).—3. Forms ether when it acts on $EtNO_3$: but it acts like Na upon ethers of organic acids; thus it converts formic ether into CO and alcohol, oxalic ether into CO and carbonic ether, carbonic ether into $NaCO_3Et$ and Et_2O, benzoic ether into NaOBz and Et_2O, acetic ether into sodium aceto-acetic ether (Geuther).—4. CO combines with NaOEt at 100° forming sodic propionate. Carbonic oxide passed over a mixture of NaOEt and NaOAc at 205° produce *n*-butyric acid, di-ethyl-acetic acid, mesitylenic acid, an acid $C_{10}H_{14}O_2$ (250°-260°), and two ketones $C_9H_{18}O$ and $C_{15}H_{21}O$ (Geuther, *A.* 202, 305).—5. PCl_5 gives NaCl, $PO(OEt)_3$, and EtCl.—6. With *chloroform* it forms ortho-formic ether, $CH(OEt)_3$ (Williamson a. Kay, *C. J.* 7, 224).—7. *Chlorine* forms aldehyde and acetic acid (Maly, *Z.* [2] 5, 345).—8. *Bromine* forms bromal, EtBr, and acetic ether (Barth, *B.* 9, 1456).—9. *Chloro-acetic acid* forms sodium ethyl-glycolate (Heintz, *P.* 109, 301).—10. *Iodine* forms NaI, sodic formate, and iodoform.—11. *Iodoform* is reduced by NaOEt to methylene iodide.—12. *Nitrobenzene* is reduced to azoxybenzene, azobenzene, and aniline (Béchamp a. Saint-Pierre, *C. R.* 47, 24).

Thallium ethylate TlOEt. S.G. 3·5 to 3·685.—Formed by heating EtOH with thallium at 100° (Church), or by exposing thallium to the vapour of alcohol in a bell-jar full of oxygen (Lamy, *A. Ch.* [4] 3, 373). It may be solidified by great cold. It dissolves in dry alcohol or ether, but addition of a trace of water causes separation of thallous hydrate. TlOEt is slowly decomposed by $CHCl_3$ with separation of TlCl.

ALCOHOLS.—The term alcohol, originally limited to one substance, viz. spirit of wine, is now applied to a large number of compounds, many of which, in their external characters, exhibit but little resemblance to common alcohol. All alcohols are compounds of carbon, hydrogen, and oxygen, and are derived from hydrocarbons containing even numbers of hydrogen-atoms by substitution of one or more hydroxyl-groups, OH, for an equal number of hydrogen-atoms: thus from propane C_3H_8 or $CH_3.CH_2.CH_3$, are derived the three following alcohols:—

Propyl alcohol $C_3H_8O = C_3H_7(OH)$
Propylene alcohol $C_3H_8O_2 = C_3H_6(OH)_2$
Propenyl alcohol or glycerin $C_3H_8O_3 = C_3H_5(OH)_3$

Alcohols are classed as monohydric, dihydric, trihydric, &c., or generally as mono- and poly-hydric, according to the number of hydroxyl-groups which they contain.

An alcohol is saturated or unsaturated according to the nature of the hydrocarbon from which it is derived. Thus, all the three alcohols derived from propane C_3H_8, which is a saturated hydrocarbon, are themselves saturated molecules not capable of forming addition-compounds; but from the unsaturated hydrocarbon C_3H_6 is derived the unsaturated compound allyl alcohol, C_3H_6O or $C_3H_5(OH)$, which is capable of taking up 2 at. bromine and forming the compound $C_3H_6Br_2O$.

The replacement, partial or total, of the hydroxyl in an alcohol by Cl, Br, I, or F, gives rise to haloid ethers; thus:

From $C_3H_7(OH)$ are derived C_3H_7Cl, C_3H_7Br, &c.

From $C_3H_6(OH)_2$ are derived $C_3H_6Cl(OH)$, $C_3H_6Cl_2$, &c.

From $C_3H_5(OH)_3$ are derived $C_3H_5Cl(OH)_2$, $C_3H_5Cl_2(OH)$, $C_3H_5Cl_3$, &c. These substitutions are effected by treating the alcohols with the chlorides, bromides, and iodides of hydrogen and phosphorus, as in the formation of ethyl chloride from ethyl alcohol:

$$C_2H_5OH + HCl = H(OH) + C_2H_5Cl$$
$$3C_2H_5(OH) + PCl_3 = P(OH)_3 + 3C_2H_5Cl$$
$$3C_2H_5(OH) + POCl_3 = PO(OH)_3 + 3C_2H_5Cl.$$

Instead of the bromides and iodides of phosphorus, a mixture of phosphorus and bromine or iodine, in the proportions required to form them, are often used in these processes.—The haloid ethers are also formed in many instances by direct substitution of chlorine &c. for hydrogen in hydrocarbons.

The treatment of the alkyl chlorides, bromides, or iodides with aqueous caustic alkalis gives rise to a substitution opposite to that shown in the above equations, reconverting the ethers into alcohols; *e.g.* $C_2H_5Cl + KOH = KCl + C_2H_5(OH)$. A considerable portion of the alcohol thus formed is, however, converted by dehydration into the corresponding olefin: *e.g.* $C_3H_8O - H_2O = C_3H_6$. A better yield of alcohol is obtained by heating the haloid ether with moist silver oxide, which acts like a hydroxide AgOH; and a still better method is to convert the alcoholic chloride, &c. into an acetate by heating it with silver acetate or potassium acetate, and to boil the resulting alkyl acetate with caustic potash or soda;

$$C_2H_5Cl + KC_2H_3O_2 = KCl + C_2H_5.C_2H_3O_2$$
$$C_2H_5.C_2H_3O_2 + KOH = KC_2H_3O_2 + C_2H_5OH.$$

This reaction is of great importance in the preparation of some of the higher alcohols.

The replacement of the hydroxyl in an alcohol by the corresponding radicles, methoxyl OCH_3, ethoxyl OC_2H_5, &c.—or of the hydrogen in the OH by Me, Et, &c., gives rise to simple or mixed alkyl oxides or ethers: thus EtOH yields EtOK, EtOMe, and EtOEt; and ethylene alcohol $C_2H_4(OH)_2$ yields $C_2H_4(OH)(OEt)$ and $C_2H_4(OEt)_2$. These substitutions may be effected in various ways, the simplest being to replace a H-atom in the alcohol by K or Na, and act on the resulting compound with a haloid ether; *e.g.*

$$2C_2H_4(OH)_2 + Na_2 = 2C_2H_4(OH)(CNa) + H_2;$$
$$C_2H_4(OH)(ONa) + EtI = NaI + C_2H_4(OH)(OEt).$$

These oxides may be looked upon as anhydrides formed by elimination of one molecule of water

from two molecules of the same or different alcohols.

In the polyhydric alcohols, where the two hydroxyls occur in the same molecule, the elimination of water gives rise to another class of oxides; thus from ethylene alcohol $C_2H_4(OH)_2$ is derived ethylene oxide C_2H_4O.

The replacement of the hydrogen in an **alcohol** by acid radicles produces alkyl salts (also called *compound ethers or esters*); thus from methyl alcohol, MeOH, are derived a nitrate $MeONO_2$, an acetate MeOAc, an acid sulphate $Me.O.SO_3H$ and a normal sulphate $(MeO)_2SO_2$. **These** alkyl salts may also be derived from the **corresponding** acids by substitution of alkyl-radicles for hydrogen, being indeed related to **the** alcohols in the same manner as metallic **salts** to metallic hydroxides. They may also be looked upon as anhydrides formed by elimination of a molecule of water between one molecule of an alcohol and one molecule of an **acid.** By distillation with alkalis they are resolved into acid and alcohol; *e.g.*

$$EtOAc + KOH = KOAc + EtOH.$$

MONOHYDRIC ALCOHOLS.

1. Series $C_nH_{2n+2}O$ or $C_nH_{2n+1}OH$. Of this **series** the following members are at present **known, each** being derived from the corresponding **paraffin** C_nH_{2n+2} by substitution of OH for H: **thus**

Methyl Alcohol	$CH_3.OH$
Ethyl „	$C_2H_5.OH$
Propyl „	$C_3H_7.OH$
Butyl „	$C_4H_9.OH$
Amyl „	$C_5H_{11}.OH$
Hexyl „	$C_6H_{13}.OH$
Heptyl „	$C_7H_{15}.OH$
Octyl „	$C_8H_{17}.OH$
Ennyl or Nonyl Alcohol	$C_9H_{19}.OH$
Decyl Alcohol	$C_{10}H_{21}.OH$
Hendecyl „	$C_{11}H_{23}.OH$
Dodecyl „	$C_{12}H_{25}.OH$
Tetradecyl „	$C_{14}H_{29}.OH$
Hexadecyl or Cetyl Alcohol	$C_{16}H_{33}.OH$
Octadecyl Alcohol	$C_{18}H_{37}.OH$
Ceryl Alcohol	$C_{27}H_{55}.OH$
Melissyl or Myricyl Alcohol	$C_{30}H_{61}.OH$

The first and second of these alcohols do **not** admit of isomeric modifications; for supposing, as is most probable, that all the hydrogen-atoms in the paraffins methane CH_4 and ethane $CH_3.CH_3$ have the same value and are attached **to** their respective carbon-atoms in the same way, the result of the substitution of OH for H in them must be the same, whichever of the hydrogen-atoms is thus replaced. But in all the higher terms of the series the case is different. Thus in propane, $CH_3.CH_2.CH_3$, the substitution may take place either in one of the exterior groups CH_3, or in the middle group CH_2, giving rise to two alcohols of different structure, distinguished as primary and secondary, viz.

$$\underset{\text{Primary}}{CH_3.CH_2.CH_2OH} \quad \cdot \quad \underset{\text{Secondary}}{CH_3.CHOH.CH_3}$$

In the primary alcohols the carbon-atom ted; 40, 2 hydroxyl is connected immediately with alcohol 1 other carbon atom, that namely called *detonating* ; but in the secondary alcohol (Zeise, *loc. cit.*).—41. o other carbon-atoms, and **these are the only forms of a 3-carbon alcohol of the series.**

The 4-carbon alcohol of the series admits of a greater number of modifications. For in the first place, the hydrocarbon, butane, C_6H_8, from which it is derived, is itself susceptible of two forms, viz., *Normal butane* $CH_3.CH_2.CH_2.CH_3$ and *Isobutane* $CH_3.CH(CH_3)_2$; and further the first of these hydrocarbons is capable of yielding one primary and one secondary alcohol—these terms having the meanings above explained—while the second yields another primary alcohol, and likewise a tertiary alcohol, in which the C-atom joined to the hydroxyl is linked also to three other atoms of carbon. These four derivatives are represented by the following formulæ:—

Normal Primary $CH_3.CH_2.CH_2.CH_2OH$.
Isoprimary $(CH_3)_2CH.CH_2OH$.
Secondary $CH_3.CH(OH).CH_2(CH_3)$.
Tertiary $(CH_3)_2C(OH).CH_3$.

The higher alcohols of the series admit of a still larger number of isomeric modifications; but all these alcohols must be either primary, secondary, or tertiary; for the C-atom joined to the OH cannot be joined to a number of other carbon-atoms greater than three. In other words the replacement of an H-atom by the group OH must take place, either in a methyl-residue CH_3, a methylene-residue CH_2, or a methenyl residue CH, producing respectively a primary, secondary, or tertiary, alcohol.

A very convenient nomenclature for these isomeric alcohols has been introduced by Kolbe (*A.* 132, 102). Methyl alcohol is called carbinol and the higher alcohols named as its substitution-products, thus:

Carbinol or Methyl Alcohol CH_3OH.
Methyl-carbinol or Ethyl Alcohol $MeCH_2OH$.
Ethyl-carbinol or Propyl Alcohol $EtCH_2OH$.
Dimethyl-carbinol or Isopropyl Alcohol Me_2CHOH.
Propyl-carbinol or Butyl Alcohol $PrCH_2OH$.
Isopropyl-carbinol or Isobutyl Alcohol $PrCH_2OH$.
Methyl-ethyl-carbinol or Secondary Butyl Alcohol MeEtCHOH.
Trimethyl-carbinol or Tertiary Butyl Alcohol Me_3COH.

Primary, secondary, and tertiary alcohols are distinguished from one another by their products of oxidation. The primary alcohols of the series $C_nH_{2n+2}O$, containing the group CH_2OH, are converted by oxidation with chromic acid mixture, first into the corresponding aldehydes, by removal of H_2, or conversion of CH_2OH into CHO, and then by further oxidation into fatty acids $C_nH_{2n}O_2$; thus:

$$\underset{\text{Propyl Alcohol}}{CH_3.CH_2.CH_2OH} + O = H_2O + \underset{\text{Propionic Aldehyde}}{CH_3.CH_2.CHO}$$

$$CH_3.CH_2.CH_2OH + O_2 = H_2O + \underset{\text{Propionic acid}}{CH_3.CH_2.COOH}$$

A secondary alcohol on the other hand which contains two alcohol-radicles united by CHOH, is converted, by removal of H_2 from this group, into a ketone, *i.e.* a compound consisting of two alcohol-radicles united by the group CO, thus:

$$\underset{\text{Secondary Propyl Alcohol}}{CH_3.CHOH.CH_3} + O = H_2O + \underset{\text{Dimethyl Ketone}}{CH_3.CO.CH_3}$$

Conversely the aldehydes treated with nascent

hydrogen (action of sodium-amalgam) are converted into primary alcohols, and the ketones into secondary alcohols.

Tertiary alcohols do not yield by oxidation either aldehydes or ketones, or acids containing the same number of carbon-atoms as themselves, but are split up into bodies containing smaller numbers of carbon-atoms—tertiary butyl alcohol for example into formic and propionic acids:

$$(CH_3)_3COH + O_4 = CH_2O_2 + C_3H_6O_2 + H_2O.$$

The three classes of alcohols may also be distinguished by the following test:—A quantity of dry silver nitrite, mixed with an equal weight of dry sand, is introduced into a small distillation-flask fitted with a side-tube; the iodide of the alcohol under examination is then added; the mixture, after the reaction has begun, is distilled; and the distillate, received in a test-tube, is shaken up with potassium nitrite and potash-ley, and then acidulated with dilute sulphuric acid. If no coloration of the mass ensues, the alcohol-radicle present is a tertiary, whereas a red coloration indicates the presence of a primary, and a blue coloration that of a secondary, radicle. The reaction may be recognised with great distinctness with the use of not more than 0·3 to 0·5 grm. of the alcoholic iodide (Meyer a. Locher, *B.* 7, 1510). Secondary hexyl iodide does not give this test.

2. Series $C_nH_{2n}O$. The most important member of this series is allyl alcohol C_3H_6O, which is a primary alcohol, convertible by oxidation into acrylic aldehyde C_3H_4O, and acrylic acid $C_3H_4O_2$. They are unsaturated compounds capable of taking up 2 at. bromine, and forming the compounds $C_nH_{2n}Br_2O$.

3. Series $C_nH_{2n-2}O$. This series includes propargyl alcohol, di-allyl-carbinol, and the higher homologues of the latter.

4. Series $C_nH_{2n-6}O$. These alcohols are derived from the aromatic hydrocarbons, C_nH_{2n-6}, in the same manner as the fatty alcohols $C_nH_{2n+2}O$ from the paraffins. The lowest member, viz., phenol C_6H_6O or $C_6H_5(OH)$, which may be formed from benzene, C_6H_6, by oxidation with H_2O_2 or with nascent ozone (Leeds, *B.* 14, 96), is the only alcohol of the series containing 6 at. carbon. The higher terms admit of isomeric modifications: for all the homologues of benzene may be regarded as derived from benzene by substitution of one or more of its hydrogen atoms by alcohol radicles C_nH_{2n+1}, and the formation of an alcohol from such a hydrocarbon by substitution of OH for H may take place either in the benzene nucleus or in one of the substituting alcohol-radicles: thus from toluene $C_6H_5.CH_3$ may be obtained the two alcohols, $C_6H_5.CH_2OH$ (benzyl alcohol) and $C_6H_4(OH).CH_3$ (cresol), and the higher hydrocarbons of the series are capable of yielding a still greater number of metameric alcohols. The properties of the compounds thus formed differ considerably, according as the hydroxyl is introduced into the benzene nucleus, or into one of the associated alkyls. The compounds formed in the latter case—benzyl alcohol for example—are true alcohols analogous in all their reactions to those of the fatty series; but those in which the OH replaces a hydrogen-atom in the benzene nucleus (phenols) exhibit very different properties, the hydroxyl being much less easily displaced by other radicles (Cl, Br, &c.), *v.* Phenols).

5. Series $C_nH_{2n-8}O$. To this series belong cinnamyl alcohol $C_9H_{10}O$, cholesterin $C_{26}H_{44}O$, and allyl-phenol $C_9H_{10}O$.

DIHYDRIC ALCOHOLS.

These alcohols are derived from hydrocarbons by substitution of two HO-groups for two H-atoms, and may therefore be regarded as compounds of divalent alkyls with hydroxyl. Two series of them are known, viz., glycols derived from the fatty hydrocarbons, and dihydric phenols from the aromatic hydrocarbons.

H. W.

The lower glycols are described as Glycol, Propylene glycol, and *tri*-Methylene glycol, but the higher members as *di*-Oxy-butane, -pentane, &c. Unsaturated glycols are described as *di*-Oxy-butinene, -hexinene, and -heptinene. The chief di-hydric phenols are Pyro-catechin, Resorcin, and Hydroquinone. *Di*-Oxy-napthalene and *di*-Oxy-anthracene belong to this class.

TRIHYDRIC ALCOHOLS.

This class is represented by five fatty alcohols: Glycerin, and *tri*-Oxy-butane, -pentane, -hexane, and -hexinene. There are also several aromatic representatives, *e.g.* Pyrogallol, Phloroglucin, and *tri*-Oxy-napthalene.

TETRAHYDRIC ALCOHOLS.

Erythrite is the only fatty tetra-hydric alcohol known. Tetra-oxy-benzene and tetra-oxy-tetra-phenyl-ethane, and tetra-oxy-tri-phenyl-methane are aromatic tetra-hydric alcohols.

PENTAHYDRIC ALCOHOLS.

Pinite and quercite are the only ones known.

HEXAHYDRIC ALCOHOLS.

Mannite, dulcite, sorbite, perseite and hexa-oxy-diphenyl make a complete list.

Formation of Alcohols.—1. From haloid ethers as described above.—2. From aldehydes or ketones by reducing with sodium-amalgam.—3. From acid anhydrides by reduction with sodium-amalgam (Linnemann).—4. From primary amines by the action of nitrous acid; this reaction is, however, accompanied by an intra-molecular change in the case of all fatty amines except ethylamine and methylamine. As a result of this change *n*-propylamine gives rise to secondary as well as *n*-propyl alcohol.—5. *Secondary Alcohols* may be got by the action of zinc alkyls upon aldehydes:

$$RCHO + ZnEt_2 = R.CHEt.OZnEt$$

$$R.CHEt.OZnEt + H_2O =$$
$$R.CHEt.OH + EtH + ZnO$$

6. *Tertiary alcohols* can be formed, similarly, from zinc alkyls and acid chlorides:

$$CH_3.CO.Cl + ZnMe_2 = CH_3.CClMe.OZnMe$$

$$CH_3.CClMe.OZnMe + ZnMe_2 =$$
$$CH_3.CMe_2.OZnMe + ClZnMe$$

$$CH_3.CMe_2.OZnMe + H_2O =$$
$$CH_3.CMe_2OH + ZnO + CH_4$$

v. Zinc-methyl.—7. From olefines, by dissolving them in H_2SO_4 and distilling the product with water: $Me_2C{:}CH_2 + H_2SO_4 = Me_3C.O.SO_3H$

$$Me_3C.O.SO_3H + H_2O = Me_3C.OH + H_2SO_4.$$

Just as: $C_2H_4 + H_2SO_4 = C_2H_5SO_4H$
$C_2H_5HSO_4 + H_2O = C_2H_5OH + H_2SO_4$.
By this reaction primary alcohols can be turned into secondary.—Thus conc. H_2SO_4 converts propyl alcohol into propylene, which is converted by the above treatment into iso-propyl alcohol.

Reactions of Alcohols.—Besides the general reactions mentioned above, the following are important:—1. Any reaction that might be expected to produce an alcohol of the form R.CH:CH.OH, produces an aldehyde, $R.CH_2.CHO$, instead (Erlenmeyer, *B.* 13, 309; 14, 320). Similarly an alcohol of the form R.CH:CR'.OH becomes a ketone, $R.CH_2.CR'O$.—2. On heating methyl, ethyl, butyl, octyl, and capryl alcohols with ammoniacal $ZnCl_2$ at 240°–280° a mixture of the mono-, di- and tri-alkylamines is got, the yield of which amounts to 50–75 p.c. of the alcohol (Merz a. Gasiorowski, *B.* 17, 623).—3. Tertiary alcohols differ from primary and secondary alcohols in not combining with *baryta* (Menschutkin, *J. R.* 10, 368).—4. Conc. HNO_3 converts tertiary alcohols into nitro-alkylenes, thus $(CH_3)_3COH$ becomes nitro-iso-butylene $C_4H_7NO_2$ (*Bn.* 1, 232).—5. The *boiling-points* of tertiary alcohols are lower than those of the isomeric secondary alcohols, and these again lower than those of the isomeric primary alcohols.—6. The alcohols $C_nH_{2n+2}O$ are decomposed by *zinc dust* at 300°–350° into olefine, C_nH_{2n}, and water. Methyl alcohol gives, however, CO and hydrogen (Jahn, *M.* 1, 378).—7. *Carbonic oxide* above 100° acts upon sodium alcoholates (RONa) mixed with sodium salts ($C_nH_{2n-1}O_2Na$) as follows:

$$RONa + CO + C_nH_{2n-1}O_2Na = CHNaO_2 + C_nH_{2n-2}RO_2Na$$

the elements of NaOH being abstracted so that R displaces H. A secondary reaction is

$$RONa + CO = RCO_2Na$$

(Geuther a. Froehlich; Looss; Poetsch, *A.* 218, 56). But CO does not act on a mixture of sodic phenylate and sodic acetate at 200° (Schroeder, *A.* 221, 35), or on one of sodic ethylate and sodic benzoate at 200°. On a mixture of sodic ethylate and sodic phenylacetate CO forms various acids including one (310°–320°) which may be phenyl-vinyl-butenyl acetic acid, $Ph.C(C_2H_3)(C_2H_2Et)CO_2H$. On a mixture of NaOEt and sodic cinnamate, carbonic oxide forms di-ethyl-cinnamic acid, $C_6H_5.CEt{:}CEt.CO_2H$ and di-butyl-cinnamic acid, $C_6H_5.C(C_4H_9){:}C(C_4H_9).CO_2H$. Both are oils.—8. Primary alcohols heated with *soda-lime* form acids and give off hydrogen thus: $RCH_2OH + KOH = RCO_2K + 2H_2$ (Dumas a. Stas, *A.* 35, 129). But at a higher temperature a second reaction occurs: $RCO_2K + KOH = RH + CO_3K_2$. If the hydrogen evolved be measured, some conclusion may be drawn as to the molecular weight of the alcohol; but the lower alcohols cannot give good results, as the hydrocarbons RH are gases. Myricyl alcohol gives off $\frac{10}{11}$ of the calculated hydrogen (C. Hell, *A.* 223, 269).—9. When an *alkyl carbonate* is heated with an alcohol, exchange of radicles occurs if the radicle of the alcohol contains more carbon atoms than that of the ether (Röse, *A.* 205, 240). But when an alcohol is heated with an *acetal*, exchange takes place only if the alcohol has the smaller radicle (Geuther, *A.* 218, 45). When an alcohol is boiled with a *simple ether* or with an ether of acetic or butyric acid with inverted condenser, no change occurs (G.).—10. If a small quantity of a *secondary* alcohol, other than isopropyl alcohol, be moistened with HNO_3 and then mixed with water and shaken with ether, on adding alcoholic KOH to the residue left after evaporating the ether, yellow prisms of a potassium alkyl nitrite separate (Chancel, *C. R.* 100, 601).—11. Benzoïn, isohydrobenzoïn, and pyrocatechin give, when their sodium compounds are treated with $ClCO_2Et$, neutral carbonates of the form $R''CO_3$, while resorcin, hydroquinone, and orcin give di-carbonates, $R''(CO_3Et)_2$ (M. Wallach, *A.* 226, 87).—12. On the *Rate of Etherification* of alcohols *v.* CHEMICAL CHANGE.—13. Fe_2Cl_6 gives a colour-reaction with all oxy-compounds whether aromatic or fatty, though in the latter case the reaction is faint and a nearly colourless solution of the reagent is required. Such a solution can be prepared by diluting two drops of 10 p.c. solution of Fe_2Cl_6 with 60 c.c. of water. If an excess of the substance to be tested is added to this solution a sulphur-yellow colour will be produced if a fatty alcohol, oxy-acid, or carbohydrate is present (Landwehr, *B.* 19, 2726).

ALDANE. A term proposed by Riban (*C. R.* 75, 98) to designate products formed by the union of two or more molecules of an aldehyde, with elimination of water—*e.g.* crotonic aldehyde $CH_3.CH{:}CH.CHO$ from aldehyde.

Di-aldane $C_8H_{11}O_3$ *i.e.*
$CH_3.CH(OH).CH_2.CH{:}CH.CH(OH).CH_2.CHO$
[130°]. S. (ether) ·87 at 22°. Formed by the condensation of aldol, $CH_3.CH(OH).CH_2.CHO$, under the influence of hydrochloric acid (Wurtz, *Bl.* [2] 24, 100; 28, 169). Crystallised from water. Sl. sol. cold water, v. e. sol. boiling alcohol. May be distilled *in vacuo.* It reduces silver solution. Aqueous NH_3 at 100° forms a crystalline base, $C_{16}H_{28}N_2O_3$, v. sol. water, alcohol or ether (Wurtz, *C. R.* 91, 1030). The aqueous solution of the base deposits, after some time, an amorphous isomeride.

Iso-di-aldane $C_8H_{14}O_3$ [114°]. Formed by heating aldol at 125° (W.) or by slow action of aqueous HCN upon aldol (Lobry de Bruyn, *Bl.* [2] 42, 161).

Di-aldanic acid $C_8H_{11}O_4$ *i.e.*
$CH_3.CH(OH).CH_2.CH{:}CH.CH(OH).CH_2.CO_2H$
[80°]. (198°) at 20 mm. Formed by treating an aqueous solution of di-aldane with Ag_2O or $KMnO_4$ (Wurtz, *C.R.* 83, 255, 1259). Monoclinic crystals. V.e. sol. alcohol or water, m. sol. ether. Salts:—KA' deliquescent crystals (from 98 p.c. alcohol).—NaA': plates (from alcohol).—BaA'_2: ppd. as powder by adding ether to an alcoholic solution.—CaA'_2 *x*aq: v. e. sol. water, but not deliquescent.—AgA': small laminæ (from boiling water); insol. alcohol.

Di-aldanic alcohol $C_8H_{16}O_3$ *i.e.*
$CH_3.CH(OH).CH_2.CH{:}CH.CH(OH).CH_2.CH_2OH$
[49°–53°]. (162°–165°) at 10 mm. Prepared by reducing di-aldane in aqueous solution with a large excess of (1 p.c.) sodium amalgam, the liquid being kept slightly acid with HCl. The liquid is neutralised and evaporated, freed from NaCl by alcohol, and the alcoholic solution distilled (Wurtz, *C. R.* 92, 1371). White, crystalline, deliquescent mass. V. e. sol. water and

alcohol; v. sol. ether. Ac_2O forms an **acetate** $C_8H_{14}Ac_2O_3$ (c. 159°) at 20 mm. Di-aldanic alcohol does not reduce ammoniacal $AgNO_3$.

Constitution.—The formation of a di-acetate seems inconsistent with the constitution assigned to di-aldanic alcohol. Di-aldane may be considered to be derived from di-aldol,

$$CH_3.CH(OH).CH_2.CH(OH).CH_2.CH(OH).CH_2.CHO,$$

by removal of H_2O. If this dehydration is to destroy two hydroxyls an anhydride must be formed:

$$\underbrace{CH_3.CH.CH_2.CH}_{O}.CH_2.CH(OH).CH_2.CHO$$

and the formulæ of dialdane derivatives must be altered accordingly.

ALDEHYDE (ACETIC) C_2H_4O, *i.e.* $CH_3.CHO$. Mol. w. 44. (21°). S.G. ^{0} ·800 (Kopp, *A.* 64, 214); $\frac{20}{4}$ ·7799 (Brühl); $\frac{10}{10}$ ·7951; $\frac{16}{16}$ ·7876 (Perkin, *C. J.* 45, 475). S.V. 56·6 (Ramsay). μ_β 1·3359. R_∞ 18·18 (B.). H.F.p. 48,740 (Thomsen); 46,000 (Berthelot). H.F.v. 47,870. M.M. 2·383 at 16·3°. V.D. 1·532 (for 1·520).

Occurrence.—In the first portions obtained by rectifying spirit that has been filtered through charcoal, where it is perhaps formed by oxidation in the charcoal (Krämer a. Pinner, *B.* 2, 403; 4, 787; Kekulé, *B.* 4, 718). The name *aldehyde* was invented by Liebig as a contraction of *alcohol dehydrogenatum.*

Formation.—1. In the oxidation of alcohol, either by slow combustion in contact with platinum black, or by the action of CrO_3, chlorine water, HNO_3, or a mixture of H_2SO_4 and MnO_2 (Liebig, *A.* 14, 133). Also by oxidation of acetic ether and other ethyl compounds (*e.g.* ethylamine, Carstanjen, *J. pr.* 89, 486), and by slow combustion of ether.—2. By action of $ZnCl_2$ on glycol: $C_2H_4(OH)_2 = H_2O + C_2H_4O$ (Wurtz, *A.* 108, 86).—3. From ethylene bromide and water at 160° (Carius, *A.* 131, 172) $C_2H_4Br_2 + H_2O = C_2H_4O + 2HBr$. From ethylene bromide and mercuric acetate (Linnemann, *A.* 143, 347).—4. From ethylene and CO_2 at 400° (Schützenberger, *Bl.* 31, 482).—5. From acetylene and aqueous $HgBr_2$ (Kutscheroff, *B.* 14, 1540).—6. By electrolysis of potassic lactate (Kolbe, *A.* 113, 244), of sugar solutions (H. T. Brown, *C. J.* 25, 578), or of alcohol containing H_2SO_4 or KOH (Jaillard, *C. R.* 58, 1203).—7. By dissolving acetylene in dilute H_2SO_4 (S.G. 1·35) and distilling the product with water (Lagermark a. Eltekoff, *B.* 10, 637).—8. By the dry distillation of a mixture of calcic acetate and calcic formate $Ca(CO_2CH_3)_2 + Ca(CO_2H)_2 = 2CaCO_3 + 2HCO.CH_3$ (Ritter, *A.* 97, 369).—9. By oxidation of ethylene with aqueous CrO_3 at 120° (Berthelot, *C. R.* 68, 334).—10. By reducing chloral with zinc and dilute H_2SO_4 (Personne, *C. R.* 71, 227).—11. Together with formic acid by heating lactic acid with dilute H_2SO_4 at 130°:

$$CH_3.CH(OH).CO_2H = CH_3.CHO + HCO_2H$$

(Erlenmeyer, *Z.* [2] 4, 343). Also, together with lactide, by the dry distillation of lactic acid.—12. Among the products of the action of H_2SO_4 and MnO_2 or $K_2Cr_2O_7$ upon albumen, fibrin, caseïn, gelatin (Guckelberger, *A.* 64, 46, 86), or gluten (Keller, *A.* 72, 31).—13. By heating acetal with glacial acetic acid at 180° for two days (Beilstein, *C. R.* 48, 1121).—14. By passing alcohol through a red-hot tube. From hemp oil in the same way (Hess, *P.* 38, 380). Aldehyde occurs among the products of the dry distillation of wood (Kane, *A.* 19, 288; Krämer, a. Grodzki, *B.* 9, 1921; Mabery, *Am.* 5, 258), and of sugar (Völckel, *A.* 87, 303).—15. By distilling α-di-alkylated-β-oxy-propionic acids:

$$CH_3.CH(OH).CEt_2.CO_2H = CH_3.CHO + CHEt_2CO_2H.$$

Preparation.—1. From the 'first runnings' in the rectification of fermented liquors.—2. Alcohol (3 pts. of S.G. ·842) and $K_2Cr_2O_7$ (3 pts.) are placed in a retort and conc. H_2SO_4 (4 pts.) is slowly run in. The heat evolved causes the aldehyde to distil off (W. a. R. Rodgers, *J. pr.* 40, 240). It is collected in dry ether, which is afterwards saturated with dry NH_3; aldehyde-ammonia separates in cubes, and this is distilled with H_2SO_4 (3 pts.) mixed with water (4 pts.), the receiver being cooled with ice and salt. The product is dried over $CaCl_2$ and rectified.

Properties.—Characteristic odour, miscible with water, but separated by $CaCl_2$ from solution. Neutral. Readily polymerised. Mixes with alcohol and ether. A mixture of aldehyde (1 pt.) and water (3 pts.) boils at 37°. Aldehyde dissolves S, P, and I. Burns with blue flame. It dissolves 7 times as much SO_2 as water does.

Tests.—1. Heated with ammoniacal silver nitrate forms a mirror.—2. Heated with aqueous potash forms a yellow body (aldehyde resin) and gives off a characteristic odour (Weidenbusch, *A.* 66, 153). The solution then contains formate and acetate.—3. Restores the colour to a solution of a rosaniline salt that has been bleached by SO_2.—4. Reacts with hydroxylamine forming a liquid oxim (*v. infra*).—5. Reacts with phenylhydrazine forming a crystalline phenyl-hydrazide (*v. infra*).—6. Combines with $NaHSO_3$.—7. Combines with NH_3.—8. H_2S passed into an aqueous solution forms an oil, converted by acids into solid thio-aldehyde (*q. v.*).—9. Alkaline aqueous solutions produce a red coloration when treated with diazo-benzene sulphonic acid and a little sodium-amalgam.

Reactions.—1. *Oxidised* to acetic acid slowly by *air*, more rapidly in presence of platinum black, most rapidly by oxidising agents.—2. Passed over red-hot *soda lime*, it forms sodic acetate and hydrogen. Passed over red-hot *quicklime*, it gives acetone and various ketones and gases (Schloemilch, *Z.* [2] 5, 336).—3. HI at high temperatures reduces it to ethane (Berthelot, *Bl.* [2] 7, 59).—4. *Sodium amalgam* reduces it to alcohol, some di-oxy-butane being also formed (Kekulé, *A.* 162, 309).—5. Converted into crotonic aldehyde (*q. v.*) by $ZnCl_2$ or by aqueous solutions of *sodic acetate* or *Rochelle salt* at 100°. *Zinc shavings* at 100° produce an aldehyde $C_6H_{10}O_2$ (220°); it is an oil and combines with $NaHSO_3$ (Riban, *Bl.* [2] 18, 63).—6. With *chlorine* forms, in sunlight, acetyl chloride (Wurtz, *A.* 102, 93).—7. *Chlorine* passed into aqueous aldehyde forms chloral, butyro-chloral, dichloraldehyde, and other bodies (Pinner, *A.* 179, 21; *B.* 8, 1321, 1561; Wurtz a. Vogt, *Bl.* 17, 402). *Bromine* converts aldehyde, dissolved in acetic ether, into bromal and di-bromo-aldehyde.—8. PCl_5 gives ethylidene chloride, $CH_3.CHCl_2$ (Beilstein, *A.* 113, 110). $COCl_2$ acts similarly (Eckenroth, *B.* 18, 518).—9. PCl_3Br_2 gives ethylidene bromide, $CH_3.CHBr_2$ (Paterno a. Pisati, *B.* 5, 289).—10. Dry HCl passed into cold aldehyde forms ethylidene chlorhydrin $CH_3.CHCl.OH$, (25°) at 40 mm. This changes spontaneously, or more quickly if heated or treated with HCl, into 'ethylidene oxy-chloride,' $C_4H_8Cl_2O$, (c. 59°) at 40 mm. A small quantity of another body, $C_8H_{12}Cl_2O$, (c. 100°) at 40 mm., is also got. Ethylidene oxy-chloride is probably di-chloro-di-ethyl oxide $(CH_3.CHCl)_2O$. It is converted by boiling water into aldehyde and HCl, and by ammonia into efflorescent needles of $(CH_3.CHNH_2)_2O\,2HCl$ (Lieben, *C. R.* 46, 662; Kessel, *A.* 175, 46; Hanriot, *C. R.* 92, 302). Aldehyde saturated with HCl is converted into crotonic aldehyde (*q. v.*), chloro-butyric aldehyde, and a compound $C_{10}H_{18}Cl_2O_3$ [98°] (Kekulé, *A.* 162, 102).—11. Aldehyde left for some days with aqueous HCl forms aldol (*q. v.*).—12. HCl passed into a mixture of aldehyde and alcohol forms chloro-ethyl ether (*q. v.*).—13. HCl passed into a mixture of aldehyde and *mercaptan* forms di-thio-acetal $CH_3.CH(SEt)_2$, a mobile liquid (Baumann, *B.* 18, 884).—14. Aldehyde forms with *zinc ethyl* a compound which is decomposed by water with production of secondary butyl alcohol (*q. v.*).—15. When paraldehyde (1 g.) is added to cold H_2SO_4 (100 g.) and the solution is shaken with *benzene*, di-phenyl-ethane is got:

$$CH_3.CHO + 2C_6H_6 = CH_3.CH(C_6H_5)_2 + H_2O$$

(Baeyer, *B.* 7, 1190).—16. With *cyanamide* it forms a compound $(C_2H_4)_3N_3Cy_3Aq$ (Knop, *A.* 131, 253).—17. With HCN it gives lacto-nitrile (*q. v.*). 18. With HCN, HCl, and NH_3 in aqueous solution it gives, on boiling, alanine (*q. v.*). A mixture of aldehyde-ammonia and HCN in 30 p.c. solution acidified by HCl gives in the cold amido-propionitrile, which changes first to imido-propionitrile, and then, in about a month, to hydrocyanaldine.

Hydrocyanaldine $C_9H_{12}N_4$. [115°]. S. ·18 at 20°. S. (alcohol) 1·27 at 18°. Prisms (from ether). May be sublimed. V. sol. acetone, m. sol. ether, v. sl. sol. CS_2. Decomposed into its components by boiling $AgNO_3$ or boiling KOH.

Parahydrocyanaldine $C_9H_{12}N_4$. [232°]. S. ·01 at 20°; S. (alcohol) ·04 at 18°. This is a similar body formed by allowing the liquid containing hydrocyanaldine to stand several months, and also by warming a mixture of amido- and imido- propionitrile with HCl. Rhombic crystals (from acetone). Insol. ether, v. e. sol. acetone. Decomposed by $AgNO_3$ or KOH like hydrocyanaldine.

Combinations.—1. With *bisulphites of the alkalis*: $C_2H_4ONaHSO_3Aq$: pearly plates by evaporation over H_2SO_4; satiny needles when ppd. by alcohol.—$C_2H_4OKHSO_3$: hard indistinct crystals composed of minute needles.—$(C_2H_4O)_2Ba(HSO_3)_2$: soluble scales.—If a solution of $(NH_4)HSO_3$ be mixed with aldehyde and evaporated, it deposits crystals of $C_2H_4OSO_2NH_3$, S. 16 at 16° (Bunte, *A.* 170, 305). But by passing SO_2 into alcoholic aldehyde-ammonia, Redtenbacher (*A.* 65, 37) got unstable needles of an isomeric body, S. 70 at 16°. When strongly heated with potash-lime, this decomposed with production of di-methyl-amine or ethylamine (Gössmann, *A.* 91, 122).—It may be $C_2H_4ONH_4HSO_3$ (Beilstein).—The compound of aldehyde with acid sodium sulphite may perhaps be represented by the formula $CH_3.CH(OH).SO_2Na$, as *a*-oxy-ethyl sodium sulphite.

2. With *ammonia*: $CH_3.CH(OH).NH_2$.

Aldehyde-ammonia [70°-80°]. (100°). V.D. 80·36. By passing NH_3 into ethereal solution of aldehyde (Liebig, *A.* 14, 133). Rhombohedra, best got by mixing a conc. alcoholic solution with ether, very soluble in water, hardly soluble in ether. Alkaline. Turns brown in air. Decomposed by dilute acids, even by CO_2, giving off aldehyde. Reactions.—(*a*) H_2S forms thialdine (*q. v.*).—(*b*) H_2Se forms selen-aldine $C_6H_{13}NSe_2$.—(*c*) Alcoholic CS_2 forms carbo-thialdine (*q. v.*).—(*d*) HCN and HCl form, in the cold, hydrocyanaldine, $C_9H_{12}N_4$, or on heating, alanine (*q. v.*).—(*e*) At 120° in a sealed tube it forms tri-methyl-pyridine, *oxy-tetraldine* $C_8H_{13}NO$, and *oxypentaldine* $C_{10}H_{15}NO$. The two latter are monacid amorphous bases, sl. sol. water (Babo, *J. pr.* 72, 88; Heintz a. Wislicenus, *J.* 1858, 347; Schiff, *A. Suppl.* 6, 10).—(*f*) Action of SO_2 is described above.—(*g*) CS_2 forms carbothialdine $C_5H_{10}N_2S_2$ (*q. v.*).—(*h*) NaOEt and MeI in the cold form isocholine iodide, $C_5H_{14}NOI$ (G. Meyer, *B.* 16, 207).

3. With *ammonia* and *silver nitrate* or *sulphate*: When $AgNO_3$ (100 c.c. of a $\frac{3}{5}$ normal solution) is added to aqueous NH_3 (15 c.c. four times normal) and, after filtration, aldehyde is added as long as the pp. first formed redissolves, a liquid is got in which more NH_3 (15 c.c.) causes separation of the compound $C_4H_{10}N_3O_3Ag\,\frac{1}{2}aq$, which must be washed with alcohol and ether and dried at a low temperature (Reychler, *B.* 17, 41). It forms unstable white six-sided plates. Sl. sol. water, v. sl. sol. alcohol, insol. ether. Its warm aqueous solution deposits a silver mirror.—If the same solutions be mixed in the following proportions: 20 c.c. NH_3Aq, 33 c.c. $AgNO_3Aq$ and 20 c.c. aldehyde, and 250 c.c. alcohol be added, a white microcrystalline pp. $C_4H_{10}N_3O_3Ag$ is got. This body is represented by Liebermann a. Goldschmidt (*B.* 10, 2179; 11, 1198) as $AgNO_3 2C_2H_4NH$;

Reychler writes $AgO.N\left(\Big\langle{NH \atop O}\Big\rangle CH.CH_3\right)_2$.—

$Ag_2SO_4(C_2H_4NH)_3 3aq$.—$Ag_2SO_4(C_2H_4NH)_4 6aq$.—$Ag_2SO_4(C_2H_4NH)_3NH_3\,3aq$ (W. G. Mixter, *Am. S.* [3] 17, 427).

4. A solution of aldehyde in *alcoholic ammonia* in six months becomes brown. If it be then evaporated, *tri-ethylidene diamine*, or *hydracetamide* $(CH_3.CH)_3N_2$, is left as a yellow amorphous powder, soluble in water. Its hydrochloride is $C_6H_{12}N_2 2HCl$. Boiling water or acids convert it into *oxy-trialdine* $C_6H_{11}NO$, an amorphous yellow powder, soluble in water; salts.—$C_6H_{11}NO.HCl$.—$(C_6H_{11}NO)_2H_2SO_4$ (H. Schiff, *Bl.* [2] 8, 443; *A. Suppl.* 6, 1).

5. With *prussic acid*: C_2H_4OCNH *i. e.* $C_2H_4(OH)CN$, *ethylidene cyanhydrin* or lacto-nitrile (*q. v.*).—6. With *ethyl nitrate*: $C_2H_4O2EtNO_3$ (86°). S.G. ^{12} 1·045. Formed by distilling a mixture of $KEtSO_4$ with KNO_3. It is an oil. Vapour explosive. Decomposed by potash into aldehyde (Nadler, *A.* 116, 173).

7. With *ethyl chloride* v. CHLORO-DI-ETHYL OXIDE.

8. With *alkoyl chlorides* or *bromides*. The following compounds may be viewed as derived from ethylidene glycol chlorhydrin $CH_3.CH(OH)Cl$ (*v.* reaction 10), by displacement of H by acid radicles.

(*a*) **With** ***acetyl chloride*****:** $C_2H_4O, C_2H_3O.Cl$ **or** $C_2H_4(OAc)Cl$, ***ethylidene chloracetin*** **(121·5° cor.) S.G.** $\underline{15}$ **1·114. Combination takes place at 100° (M. Simpson, *Pr.* 27, 120; Franchimont, *R.* 1, 246; Rübencamp, *A.* 225, 274). The compound was discovered by Wurtz (*Z.* 1871, 362; *A. Ch.* [3], 49, 58; *C. R.* 73, 528). Decomposed by potash into KCl, acetic acid, and aldehyde. KOAc forms $CH_3.CH(OAc)_2$ (Schiff, *B.* 9, 304). Chlorine at 120°, in presence of iodine, forms $CHCl_2.CHCl.OAc$, tri-chloro-ethyl acetate (250°–280°). Bromine dropped into it at 100° forms bromethyl bromo-acetate $CH_3.CHBr.O.CO.CH_2Br$ (*v.* Bromo-acetic acid).

(*b*) With *acetyl bromide* forms a corresponding, but unstable, compound (c. 140°) (Tawildaroff, *A.* 176, 21).

(*c*) With *propionyl chloride*: $C_5H_9ClO_2$ or $CH_3.CHCl.O(C_3H_5O)$, *chloro-ethyl-propionate* (135° uncor.). S.G. $\underline{15}$ 1·071.

(*d*) With *butyrylchloride*: $CH_3.CHCl.O(C_4H_7O)$ (149° uncor.). S·G. $\underline{15}$ 1·038.

(*e*) With *valerylchloride*: $CH_3.CHCl.O(C_5H_9O)$ (c. 163°). S.G. $\underline{15}$ ·997.

Derivatives of Ortho-Aldehyde.

The following combinations between aldehyde and compounds of the form M_2O may be viewed as derivatives of ortho-aldehyde, $CH_3.CH(OH)_2$. Ortho-aldehyde itself is not known, but chloral hydrate is tri-chloro-ortho-aldehyde.

Alkyl derivatives, Acetals or *Aldehydates.* The term 'acetal,' originally applied to $CH_3.CH(OEt)_2$, is now often extended to the whole series of di-alkylated ortho-aldehydes.

These bodies are formed, together with other products, by the oxidation of alcohols. Each of them may be formed from one of its higher homologues, by heating the latter at 120°, with an alcohol containing a lower radicle. Thus di-ethyl-acetal heated with methyl alcohol yields dimethylacetal, whereas the latter heated with ethyl, propyl, isobutyl, or amyl alcohol yields only traces of an acetal containing different alcohol-radicles. Similarly diethyl-acetal heated with methyl-alcohol is converted, for the most part, into dimethylacetal, but is practically unaltered by propyl and amyl alcohols (Bachmann, *A.* 218, 38). Aldehydates may also be formed by heating aldehydes with alcohols and HCl (Wurtz a. Frapolli, *A.* 108, 226; Claus a. Trainer, *B.* 19, 3004).

Ethyl-ortho-aldehyde $CH_3.CH(OH)(OEt)$ (80°–90°) (Rénard, *B.* 8, 132) (c. 50°) (Jacobsen, *B.* 4, 215). Among the products of electrolysis of mixture of alcohol and dilute H_2SO_4 (R.). By action of water on chloro-ethyl-ether, $CH_3.CHCl.OEt$ (J.).

Di-methyl-acetal $C_4H_{10}O_2$ *i.e.* $CH_3.CH(OMe)_2$ (62·7°–63·3°) at 751·6 mm. S.G. $\underline{22}$ ·8655 (Bachmann); ·8590 at 14° (Dancer, *A.* 132, 240). V.D. 3·10 (for 3·11). S.V. 110·81 (R. Schiff, *A.* 220, 104). Occurs in crude wood spirit (D.). Formed by oxidising a mixture of MeOH and EtOH with MnO_2 and H_2SO_4 (Wurtz). Prepared by heating aldehyde (4 vols.), methyl alcohol (8 vols.), and glacial HOAc (1 vol.) at 100° (Alsberg, *J.* 1864, 485). A colourless liquid burning with a white, blue-edged flame (Wurtz, *A. Ch.* [3] 48, 373). **EtOH at 120° has hardly any action, traces of methyl-ethyl-acetal being formed. Propyl, isobutyl, and iso-amyl alcohols act similarly.**

Methyl-ethyl-acetal **$CH_3.CH(OMe)(OEt)$. Reactions that might be expected to produce this body yield only a mixture of di-methyl-acetal and di-ethyl-acetal (A. Geuther, *A.* 225, 265).**

Di-ethyl acetal *v.* Acetal.

Methyl-propyl-acetal $C_6H_{14}O_2$ *i. e.* $CH_3CH(OMe)(OPr)$ (103°–105°). Very little is formed from di-methyl-acetal and PrOH at 120°.

Ethyl-propyl-acetal $C_7H_{16}O_2$ *i. e.* $CH_3.CH(OEt)(OPr)$(124°–126°). Very little is formed from di-ethyl-acetal and PrOH at 120°.

Methyl-isobutyl-acetal $C_7H_{16}O_2$ (126°). Dimethyl-acetal (15 g.) heated with isobutyl alcohol at 120° forms a little (1 g.) of this body.

Methyl-iso-amyl-acetal $C_8H_{18}O_2$ (141°-144°). A little got from di-methyl-acetal and iso-amyl alcohol at 120°.

Di-propyl-acetal $C_8H_{18}O_2$ (146°–148°). S.G. $\underline{22·5}$ ·825. Got by passing pure PH_3 into a mixture of aldehyde and PrOH at −21° (Girard, *C. R.* 91, 629).

Di-iso-butyl-acetal $C_{10}H_{22}O_2$ (168°–170°). S.G. $\underline{22}$ ·816. Prepared like the preceding.

Di-iso-amyl-acetal $C_{12}H_{26}O_2$ *i. e.* $CH_3.CH(OC_5H_{11})_2$ (c. 195°) (Bachmann); (210·8° cor.) (Alsberg, *J.* 1864, 485; Claus a. Trainer, *B.* 19, 3008). S.G. $\underline{22}$ ·801 (B.); $\underline{15}$ ·835 (A.). Aldehyde (1 vol.) and iso-amyl alcohol (5 vols.) are mixed, saturated with SO_2 and warmed with glacial HOAc (1 vol.). A small quantity is got by heating amyl alcohol with acetal at 120°.

Ethylene-acetal $C_4H_8O_2$ *i. e.*

$CH_3CH\left\langle\begin{matrix}O\\O\end{matrix}\right\rangle C_2H_4$ (82·5°) at 766 mm. S.G. $\underline{0}$ 1·002. S. 67. From aldehyde and glycol at 100° (Wurtz, *A.* 120, 328). Separated by $CaCl_2$ from its aqueous solution. Not attacked by KOH. Acetic acid gives glycol di-acetin.

Propylene-acetal $C_5H_{10}O_2$ *i. e.*

$CH_3.CH\left\langle\begin{matrix}O\\O\end{matrix}\right\rangle C_3H_6$ (93°). From aldehyde and propylene glycol at 160° (Gramont, *Bl.* 41, 361). Decomposed by water into aldehyde and propylene glycol.

Oxy-propylene-acetal $C_5H_{10}O_3$

i.e. $CH_3.CH\left\langle\begin{matrix}O\\O\end{matrix}\right\rangle C_3H_5OH$ (c. 186°) S.G. $\underline{0}$ 1·081.

From aldehyde and glycerin at 180° (Harnitzky a. Menschutkin, *A.* 136, 126). Decomposed by water into its components.

Di-(β)-naphthyl-acetal $C_{22}H_{18}O_2$ *i.e.* $CH_3.CH(O.C_{10}H_7)_2$. [201°]. Slowly formed when (β)-naphthol and aldehyde are dissolved in acetic acid and a few drops of HCl are added (Claisen, *B.* 19, 3318). Crystals; insol. aqueous alkalis. Changed by warming with HOAc and HCl into ethylidene-di-naphthyl oxide,

$$CH_3.CH\left\langle\begin{matrix}C_{10}H_6\\C_{10}H_6\end{matrix}\right\rangle O.$$

Alkoyl derivatives or *ethylidene salts.* When both alkoyls (acid radicles) are the same, these bodies may be viewed as compounds of acid anhydrides with aldehyde. They are slowly decomposed by water, more rapidly by potash, into aldehyde and acids. Mono-alkoyl derivatives, $CH_3.CH(OH)(OR)$ are not known; **they appear to split up into water and the an-**

hydrides $\{CH_3.CH(OR)\}_2O$. These anhydrides may be formed from di-chloro-di-ethyl oxide, $(CH_3CHCl)_2O$ and sodium salts. They are volatile liquids, decomposed by water into aldehyde and acid (Geuther, *A.* 226, 223).

Di-acetyl derivative $CH_3.CH(OAc)_2$ (168·4° cor.). S.G. $\underline{15}$ 1·073. $\mu = 1·40$ at 28°. 1. From $CH_3.CHCl(OAc)$ and AgOAc (Rübencamp, *A.* 225, 274).—2. From aldehyde and Ac_2O at 180° (Geuther, *A.* 106, 249).—3. From aldehyde and AcCl at 100° (Franchimont, *R.* 1, 248).

Di-propionyl derivative $CH_3.CH(OC_3H_5O)_2$ (192·2° cor.). S.G. $\underline{15}$ 1·020 $\mu = 1·407$. From $CH_3.CHCl(OC_3H_5O)$ and $AgO(C_3H_5O)$.

Di-butyryl derivative $CH_3.CH(OC_4H_7O)_2$ (215·5° cor.). S.G. $\underline{15}$ ·9855. $\mu = 1·411$.

Di-valeryl derivative $CH_3.CH(OC_5H_9O)_2$ (225° cor.). S.G. $\underline{15}$ ·947. $\mu = 1·414$.

Acetyl-propionyl derivative $CH_3.CH(OAc)(OC_3H_5O)$ (178·6° cor.). S.G. $\underline{15}$ 1·044 $\mu = 1·402$. From $AgOC_3H_5O$ and $CH_3.CHCl.OAc$ or from AgOAc and $CH_3.CHCl.OC_3H_5O$ (Geuther a. Rübencamp, *A.* 225, 281).

Acetyl-butyryl derivative $CH_3.CH(OAc)(OC_4H_7O)$ (192·6° cor.). S.G. $\underline{15}$ 1·015 $\mu = 1·047$. From $AgOC_4H_7O$ and $CH_3.CHCl.OAc$, or from AgOAc and $CH_3.CHCl.OC_4H_7O$.

Acetyl-valeryl derivative $CH_3.CH(OAc)(OC_5H_9O)$ (194°–199° cor.). S.G. $\underline{15}$ ·991 $\mu = 1·408$. Similarly prepared.

POLYMERIDES OF ALDEHYDE.

Aldehyde readily polymerises, forming aldol $C_4H_8O_2$ (*q. v.*), paraldehyde $C_6H_{12}O_3$, or metaldehyde $C_{2n}H_{4n}O_n$. Pure aldehyde may be kept without change, but when impure it spontaneously changes to paraldehyde or metaldehyde (Weidenbusch, *A.* 66, 155; Fehling, *A.* 27, 319; Geuther a. Cartmell, *A.* 112, 16; Lieben, *A. Suppl.* 1, 114; Kekulé a. Zincke, *A.* 142, 141; *B.* 3, 468). Metaldehyde is formed from aldehyde at a low temperature by the same reagents that cause the formation of paraldehyde at high temperatures (K. a. Z.). Neither of these bodies is affected by hot potash, but both of them are converted by PCl_5 into ethylidene chloride, $CH_3.CHCl_2$, and by HCl into 'ethylidene oxy-chloride' (*v. supra*). A little alcoholic KOH converts aldehyde into a mixture of metaldehyde, paraldehyde, and a little crotonic aldehyde (Perkin, *C. J.* 43, 88).

Paraldehyde $C_6H_{12}O_3$. Mol. w. 132. [10°–12°]. (124° i. V.) (K. a. Z.); (124·4°) at 752mm. (R. Schiff, *A.* 220, 104). S.G. $\frac{20}{4}$ ·9943 (Brühl); $\frac{15}{15}$ ·9993; $\frac{4}{4}$ ·9900 (Perkin, *C. J.* 45, 479). S.V. 150·7 (S.). V.D. 4·35 (for 4·55, S.). μ_β 1·4095. R_∞ 52·48 (B.) M.M. 6·662 at 17°. S. 12 at 13°; 6 at 100°.

Preparation.—In presence of a small quantity of HCl, $COCl_2$, or SO_2, aldehyde gradually becomes hot, often reaching 40°. It is then changed to paraldehyde. H_2SO_4 and $ZnCl_2$ effect this change even more vigorously. The product is cooled to 0°, when paraldehyde crystallises.

Properties.—Colourless liquid, smelling like acetal and aldehyde. It is partially converted into aldehyde by distillation. Distillation with H_2SO_4, HCl, $ZnCl_2$, $HgBr_2$, or $COCl_2$ completely effects this change. The reactions of paraldehyde, in presence of any of these bodies, are therefore the same as those of aldehyde. It also forms $CH_3.CH(OAc)_2$ with Ac_2O. But it does not react with ammonia. HNO_3 oxidises it to glyoxal (Liubawin, *J. R.* 13, 496).

Constitution. — The S.V. agrees with that required by Kekulé's formula

$$C_2H_4\left\langle\begin{array}{l}O.C_2H_4\\O.C_2H_4\end{array}\right\rangle O$$ (Brühl, *A.* 203, 44).

Metaldehyde $C_6H_{12}O_3$. S. (chloroform) 1·034 at 26°; 4·235 at 60°; S. (benzene) ·12 at 23°, ·181 at 80°. Formed by passing a few bubbles of SO_2 or HCl into aldehyde in a freezing mixture; metaldehyde crystallises out, and the mother liquors are distilled and treated as before (K. a. Z.). $CaCl_2$ effects the same transformation at the ordinary temperature.

Properties.—Long striated prisms, sublimes about 115° without melting. Insoluble in water, slightly soluble in cold alcohol or ether. It may be converted into aldehyde: (a) by heating for a day *in vacuo* at 180°, (b) by repeatedly distilling under atmospheric pressure, (c) by heating its solution in chloroform. The vapour density may be found in the usual way, due allowance being made for its partial dissociation, the amount of undecomposed metaldehyde being estimated after cooling. The V.D. is thus found to lie between 72·2 and 59·1, the mean value being 62·5. Metaldehyde is not attacked in the cold by $KMnO_4$, chromic mixture, or NH_3. *Chlorine* forms chloral; PCl_5 gives ethylidene chloride (Hanriot a. Oeconomides, *C. R.* 93, 463; *A. Ch.* [5] 25, 226).

Di-aldehyde *v.* ALDOL.

ALDEHYDE-ACETAMIDE $C_6H_{12}N_2O_2$ *i.e.* $CH_3.CH(NHAc)_2$ *di-acetyl-ethylidene diamine* [169°]. Got by heating aldehyde with acetamide (Tawildaroff, *B.* 5, 477).

ALDEHYDE ACETATE *v.* p. 106, *l.* 6.

ALDEHYDE ACETYL CHLORIDE *v.* p. 105, *l.* 1.

ALDEHYDE ALCOHOLATE *v.* p. 105, *l.* 53.

ALDEHYDE GREEN *v.* ROSANILINE.

ALDEHYDE GUM $C_{10}H_{18}O_4$. The barium salt is formed by allowing a solution of aldehyde in baryta-water to stand for some time. From this salt H_2SO_4 liberates the 'gum' as a syrup, soluble in water and alcohol. It reddens rosaniline decolorised by SO_2, and it gives iodoform with I and Na_2CO_3. Reduces hot Fehling's solution—$Ca(C_{10}H_{17}O_4)_2$: amorphous (Tollens, *B.* 17, 660).

ALDEHYDE PHENYL-HYDRAZIDE
$C_8H_{10}N_2$ *i.e.* $CH_3.CH:N_2HPh$.
From aldehyde and phenyl-hydrazine in ether *v.* ALDEHYDES, *reaction* 4. Crystallised from benzoline. Deliquescent. V. sol. alcohol or ether. Resolved by boiling water or dilute acids into its constituents.

ALDEHYDE RESIN. Formed by the action of aqueous or alcoholic potash, hot or cold, upon aldehyde, or by heating aldehyde with NaOAc in sealed tubes at 100°. It is accompanied by a strongly smelling yellow oil which may be removed by distillation. Aldehyde resin resembles colophony. It produces, when fused with potash, oxy-iso-phthalic acid [283°], *o*-oxy-*m*-toluic acid [173°], and *m*-xylenol, $C_6H_3Me_2OH$ When strongly heated with zinc dust it gives ethyl-benzene, *m*- and *p*- methyl-ethyl-benzene and methyl-naphthalene. Conc. HNO_3 gives iso-phthalic acid (Weidenbusch, *A.* 66, 153; Ciamician, *M.* 1, 199).

ALDEHYDES.—An aldehyde is a body derived from a primary alcohol by removal of two atoms of hydrogen from each molecule, and having the general formula R.CO.H. It may therefore be looked upon as a ketone in which one alkyl is represented by H. Aldehydes may also be viewed as hydrides of acid radicles, hence $CH_3.CO.H$ is called *acetic* aldehyde and not *ethyl* aldehyde, although the latter name is, etymologically, the more correct (p. 103).

Enumeration.—In the following list the numbers denote values of *n*. $C_nH_{2n}O$. 1. Formic; 2. Acetic; 3. Propionic; 4. Butyric; 5. Valeric; 6. Hexoic; 7. Heptoic; 10. Decoic; 12. Lauric; 14. Myristic; 16. Palmitic; 17. Stearic.—$C_nH_{2n-2}O$. 3. Acrylic (acroleïn); 4. Crotonic; 5. Tiglic; 6. Hexenoic; 8. Octenoic; 14. Tetradecenoic; 15. Cimicic; 21. Tri-œnanthic.—$C_nH_{2n-6}O$. $C_{28}H_{50}O$, Tetra-œnanthic.—$C_nH_{2n-8}O$. Benzoic; Phenyl-propionic.—$C_nH_{2n-10}O_2$. Cinnamic.—$C_nH_{2n-14}O$. Naphthoic.—$C_nH_{2n-16}O$. Di-phenyl-acetic.—$C_nH_{2n}O_2$. Glycollic (?). Oxypropionic. Oxybutyric (aldol).—$C_nH_{2n-2}O_2$. Glyoxal.—$C_nH_{2n-4}O_2$. Maleic.—$C_nH_{2n-6}O_2$. Furfurol.—$C_nH_{2n-8}O_2$. Oxy-benzoic; Furfur-acrylic, Furfurcrotonic.—$C_nH_{2n-2}O_3$. Suberic. Azelaïc and Brassylic.—$C_nH_{2n-8}O_3$. Di-oxy-benzoic; Piperonal.—$C_nH_{2n-10}O_4$ Di-aldehydo-resorcin; Di-aldehydo-orcin.

Formation.—1. By oxidation of primary alcohols by air and platinum-black, by aqueous chromic acid or by H_2SO_4 and MnO_2:

$$2R.CH_2.OH + O_2 = 2R.CO.H + 2H_2O.$$

2. By distilling a mixture of barium or calcium formate with some barium or calcium salt: $Ca(O.CO.R)_2 + Ca(O.CO.H)_2 = 2CaCO_3 + 2H.CO.R$ (Limpricht, *A.* 97, 368; Piria, *A. Ch.* [3] 48, 113; Krafft, *B.* 16, 1717). This process is a particular case of Williamson's method of producing mixed ketones. Instead of calcic formate, a mixture of calcic oxalate and lime may be used (Bogusch, *J. R.* 7, 47).—3. From chlorides of the type $R.CH.Cl_2$ by heating with dry oxalic acid (Anschütz, *A.* 226, 19).—4. Chromyl dichloride, CrO_2Cl_2, unites with toluene and its homologues when added to their solution in CS_2, forming brown powders, possibly of the form $RCH(O.CrCl_2.OH)_2$, which are decomposed by water with production of aldehydes (A. Etard, *C. R.* 90, 534; 97, 909; Bornemann, *B.* 17, 1462).—5. Aromatic aldehydes may be prepared by heating dichlorides $R.CHCl_2$ with NaOHAq, or the monochlorides, $R.CH_2Cl$ with aqueous lead or copper nitrate.—6. Alcohols of the form R.CH:CH.OH appear to change, at the moment of their formation into aldehydes, $R.CH_2.CHO$. The formation of acroleïn from glycerin, and of aldehyde from bromo-ethylene are instances.—7. Some aldehydes, as benzoic, acetic, propionic, and butyric, are produced by distilling albumen, fibrin, caseïn, or gelatin, with MnO_2 and H_2SO_4. 8. Many aldehydes can be obtained from essential oils derived from plants; *e.g.*, benzoic, cinnamic, cuminic, and salicylic aldehydes.

Properties.—Almost all are volatile liquids.

Reactions.—1. Are readily *oxidised* to acids, and consequently are powerful reducing agents. Ketonic alcohols, $R.CO.CH_2OH$, resemble aldehydes in reducing power (Zincke, *A.* 216, 317).—2. Many are converted by alcoholic *potash* or by potash-fusion into an alcohol and an acid:

$$2C_6H_5.CHO + KOH = C_6H_5.CO_2K + C_6H_5.CH_2OH.$$

Glycols with double the number of carbon atoms in the molecule are often formed.—3. *Sodium-amalgam*, or zinc and glacial HOAc, reduce them to alcohols (Krafft, *B.* 16, 1714; Tiemann, *B.* 19, 355).—4. They combine with $NaHSO_3$. These compounds are usually soluble in water and in alcohol, but insoluble in saturated solutions of the bisulphites. Hence by shaking a liquid containing an aldehyde with excess of such a saturated solution, the aldehyde may be completely separated in the form of a crystalline compound. From these compounds the aldehyde may be set free by dilute H_2SO_4 or Na_2CO_3, and may then be distilled with steam (Bertagnini, *A.* 85, 179, 268).—5. They combine with *phenyl-hydrazine* (*q. v.*). A solution of phenyl-hydrazine hydrochloride (1 pt.) and sodic acetate (1½ pts.) in water (8 pts.) when added to an aqueous solution of an aldehyde or ketone, produces an insoluble compound, usually an oil appearing in drops producing a milkiness, but sometimes a crystalline pp. These compounds are not volatile with steam, but on boiling with dilute HCl they are resolved into phenyl-hydrazine hydrochloride and the aldehyde or ketone (E. Fischer, *A.* 190, 131; *B.* 15, 2252).—6. They form a silver mirror when heated with conc. ammoniacal *silver nitrate*. The reduction is promoted by adding NaOH (Tollens, *B.* 15, 1635). 7. A solution of a *rosaniline* salt, bleached by SO_2, is reddened by aldehydes, in the cold (Schiff, *Z.* 1867, 175; Caro; V. Meyer, *B.* 13, 2342). This test is not infallible (Tiemann, *B.* 14, 791); it is given by aldehyde, paraldehyde, propionic, iso-valeric, and œnanthic aldehydes, chloral, butyro-chloral, acroleïn, furfurol, benzoic, cinnamic, and furfurcrotonic aldehydes, furfuracroleïn, salicylic aldehyde, cimicic aldehyde; it is not given by chloral hydrate, formic acid, carbo-hydrates, propyl alcohol and higher alcohols, pinacone, glycol, the phenols, or quinone; a faint colour is produced after some time by acetone, and methyl and ethyl alcohols (G. Schmidt, *B.* 14, 1848).—8. Alkaline aqueous solutions produce a coloration like magenta when treated with *diazo-benzene sulphonic acid* and a little sodium-amalgam. Acetone and aceto-acetic ether give a dark red coloration without the violet shade (Penzoldt a. E. Fischer, *B.* 16, 657).—9. Aldehydes are converted by *hydroxyl-amine* into aldoxims:

$$R.CHO + H_2NOH = R.CH:NOH + H_2O$$

(V. Meyer, *B.* 15, 1164, 1324, 1525, 2784; 16, 822, 2992).—10. *u-di-methyl-p-phenylene diamine* acts vigorously on aldehydes in alcoholic solution forming crystalline compounds (A. Calm, *B.* 17, 2938): $Ph.CHO + NH_2.C_6H_4.NMe_2 =$

$$Ph.CH:N.C_6H_4.NMe_2 + H_2O.$$

11. Homologues of acetic aldehyde form crystalline compounds with *ammonia*, $R.CH(NH_2)OH$. These are converted by H_2S into sulphur bases (*v.* p. 104, *l.* 9). The aromatic aldehydes are converted by ammonia into hydramides:

$$3Ph.CHO + 2NH_3 = (Ph.CH)_3N_2 + 3H_2O.$$

Some fatty aldehydes, *e.g.* iso-butyric aldehyde (Lipp, *A.* 211, 344) behave similarly. Acroleïn loses only half its oxygen:

$$2C_3H_4O + NH_3 = C_6H_9NO + H_2O.$$

Primary and secondary bases act upon aldehydes with elimination of water. The neutral products are split up by HCl into their components. 12. *Chlorine* forms derivatives by substitution.—13. PCl_5 displaces O by Cl_2.—14. H_2S displaces O by S, forming thio-aldehydes, or their polymerides.—15. PCl_3 combines with aldehydes; the compounds are converted by water into phosphinic acids (*q. v.*).—16. PH_4I forms crystalline compounds (*v.* PHOSPHINES).—17. Aldehydes react with *alcohols* forming acetals (p.):

$$R.CHO + 2HOR' = R.CH(OR')_2 + H_2O.$$

Similarly, *mercaptans* form mercaptals (Baumann, *B.* 18, 884).—18. *Alkyl chlorides* form chlorinated ethers (*e.g.* $CH_3CHCl.OEt$). Alkoyl chlorides act similarly (p. 105, *l.* 1).—19. *Hydric cyanide* combines with aldehydes, forming α-oxy-nitriles. These nitriles give (*a*) on saponification, oxy acids, (*b*) on treatment with ammonia, amido-nitriles, whence amido acids may be got (Tiemann, *B.* 14, 1965).—20. Aldehydes may be converted into amido-acids by allowing them to stand for 30 minutes with a 3 p.c. solution of NH_4CN, and then boiling with HCl (Liubawin, *J. R.* 13, 506).—21. Benzoic aldehyde reacts with *nitro-paraffins* thus: $Ph.CHO + H_2C(NO_2).CH_3 = Ph.CH{:}C(NO_2).CH_3 + H_2O$ (Priebs, *A.* 225, 319). 22. Aldehydes condense with *aromatic compounds* with elimination of H_2O and formation of tri-substituted methanes. Thus aldehyde and benzene give di-phenyl-methyl-methane; benzoic aldehyde and phenol give di-oxy-tri-phenyl-methane; benzoic aldehyde and aniline give di-amido-tri-phenyl-methane.—23. In presence of small quantities of acids, aldehydes form red resins when warmed with *phenols*. Many of these are converted by excess of acids into crystalline isomerides. Thus benzoic aldehyde forms with pyrogallic acid prisms (from ether) of $C_{26}H_{26}O_6$; this forms an acetyl derivative $C_{26}H_{24}Ac_2O_6$. Benzoic aldehyde and resorcin form $C_{26}H_{20}O_4$. If a few drops of a liquid containing an aldehyde be boiled with an alcoholic solution of resorcin and a little HCl, and be then poured into water, a pp. is formed. This may be used as a test for presence of aldehydes (Baeyer, *B.* 5, 25; Michael a. Ryder, *B.* 19, 1388).—24. In dilute *alkaline solution* aldehydes condense with *ketones* or *other aldehydes* with elimination of H_2O, and production of complicated aldehydes or ketones.—25. For the reaction between aldehydes and *o-di-amines v.* ALDEHYDINES.

PERKIN'S SYNTHESIS OF UNSATURATED ACIDS.—Benzoic aldehyde, acetic anhydride and sodic acetate, heated together form sodic cinnamate.

In this reaction the sodic acetate may be exchanged for sodic butyrate or valerate, but the product will still be sodic cinnamate: hence Perkin concludes that the reaction takes place between the aldehyde and the anhydride. Fittig came to the opposite conclusion, viz., that the aldehyde acted on the sodium salt and that the nature of the anhydride was immaterial, thus if sodic succinate and acetic anhydride were used, the condensation took place with the sodic succinate. To this Tiemann (*B.* 15, 2061) objected that possibly the acetic anhydride acting on the sodic succinate formed sodic acetate and succinic anhydride, and that the latter reacted upon the aldehyde. Stuart (*B.* 16, 1436) then showed that when sodic malonate was used condensation took place between it and the benzoic aldehyde, although no malonic anhydride is known. He also showed that in this case glacial acetic acid might be substituted for acetic anhydride. According to Fittig, aldol-like condensation-products are first formed, and these, when they split off water, give the unsaturated acids (*A.* 227, 49). This is shown by the action of sodic iso-butyrate on benzoic aldehyde in presence of isobutyric anhydride, when the anhydride of the isobutyric derivative of β-oxy-β-phenyl-valeric acid $Ph.CH(OH).CMe_2.CO_2H$ (*q. v.*) is formed; in which there is no H for the OH to split off with. If NaOAc be used instead of sodium isobutyrate oxy-phenyl-valeric acid is still formed, a result that supports Perkin's view (Perkin, *C. J.* 49, 317).

Œnanthol and valeric aldehyde may be substituted for benzoic aldehyde in these syntheses, while the sodium salt and anhydride of propionic or *n*-butyric acid may be used instead of the corresponding derivatives of acetic acid. Condensation then takes place in the α position:

$$Ph.CHO + CH_3.CH_2.CO_2Na =$$
$$Ph.CH{:}CMe.CO_2Na + H_2O.$$

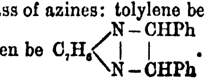
A dibasic acid can unite with one equivalent of an aldehyde for each $CH_2.CO_2H$ contained in its formula; the product may then lose H_2O, becoming a lactonic acid or an unsaturated acid.

ALDEHYDINES.—This name was formerly applied to the base $C_8H_{11}N$ obtained by heating aldehyde-ammonia, since shown to be tri-methyl-pyridine (*q. v.*). The same name has since been used by Ladenburg (*B.* 10, 1126; 11, 590, 1650) to denote bases obtained by mixing dilute aqueous solutions of aromatic *o* (but not *m* or *p*) di-amine hydrochlorides with aldehydes. Condensation occurs with evolution of heat; the yield of aldehydine after crystallisation is 60 to 70 p.c. of the theoretical. $C_xH_y(NH_2)_2 + 2H.CO.R = C_xH_yN_2C_2H_2R_2 + 2H_2O$. Thus *o*-tolylene-di-amine hydrochloride and benzoic aldehyde give rise to $C_7H_6N_2C_2H_2Ph_2$ tolylene benzaldehydine.

The same body is formed by the action of benzyl chloride on anhydro-benzoyl-tolylene di-amine at 160°,

. Hinsberg concludes from this that its formula is

(*B.* 19, 2025). Under the conditions of this experiment molecular change is more likely to occur than in the usual preparation of aldehydines in aqueous solution. All other considerations point to a symmetrical formula; and since in stability and other properties these bodies resemble the quinoxalines it is probable that, together with the latter, they belong to the class of azines: tolylene benzaldehydine would then be



. The formula given by Ladenburg is

.

Phenylene-anis-aldehydine $C_{22}H_{20}N_2O_2$ [129°]. Needles. Soluble in alcohol. Prepared by shaking anisic aldehyde with an aqueous solution of *o*-phenylene-diamine hydrochloride.

B'HCl: needles; difficultly soluble in water.

Phenylene-benzaldehydine $C_{20}H_{16}N_2$ *i.e.*

$$C_6H_4\left\langle\begin{matrix}N\text{---}CH.C_6H_5\\ N\text{---}CH.C_6H_5\end{matrix}\right.$$

[133°–134°].

Six-sided prisms. Insoluble in water, easily soluble in alcohol and benzene.

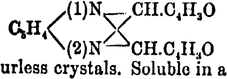
Preparation.—(1) By heating *o*-phenylene-diamine with benzaldehyde. (2) By shaking benzaldehyde with an aqueous solution of *o*-phenylenediamine hydrochloride.

Salts.—B'HCl: colourless prisms. $(B'HCl)_2PtCl_4$: yellow precipitate. $B'HNO_3$. Slightly soluble prisms. $B'_2H_2SO_4$: colourless leaflets.

Ethylo-iodide $C_{20}H_{16}N_2(C_2H_5)I$ [211°–213°]. Colourless prisms.

Methylo-iodide $C_{20}H_{16}N_2(CH_3)I$. Prisms.

Phenylene-furfur-aldehydine $C_{16}H_{12}N_2O_2$ *i.e.*



$$C_6H_4\left\langle\begin{matrix}(1)N\text{---}CH.C_4H_3O\\ (2)N\text{---}CH.C_4H_3O\end{matrix}\right.$$

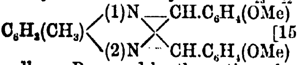
[95°–96°].

Colourless crystals. Soluble in alcohol and C_6H_6, with difficulty in ligroïn, insoluble in water. Prepared by shaking furfurol with an aqueous solution of *o*-phenylenediamine hydrochloride.

Salts. — $(B'HCl)_2PtCl_4$: yellow leaflets. $B'HNO_3$: slightly soluble needles.

Methylo-iodide $C_{16}H_{12}N_2O_2(CH_3)I$. [192°–195°]. Prisms.

Tolylene-anisaldehydine $C_{23}H_{22}N_2O_2$ *i.e.*



$$C_6H_3(CH_3)\left\langle\begin{matrix}(1)N\text{---}CH.C_6H_4(OMe)\\ (2)N\text{---}CH.C_6H_4(OMe)\end{matrix}\right.$$

[152°–156°]

Needles. Prepared by the action of anisic aldehyde on an aqueous solution of *o*-tolylene-diamine hydrochloride.

Tolylene-benzaldehydine $C_{21}H_{18}N_2$ *i.e.*

$$C_6H_3(CH_3)\left\langle\begin{matrix}(1)N\text{---}CH.C_6H_5\\ (2)N\text{---}CH.C_6H_5\end{matrix}\right.$$

[195·5°].

Colourless prisms. Forms unstable salts with acids. Prepared by heating benzaldehyde with *o*-tolylene diamine to 140°. Yield 45 p.c. of the diamine.

$B'HCl + H_2O$: long needles: difficultly soluble in strong HCl.

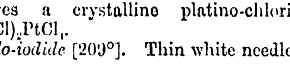
Ethylo-iodide [180°–181°]. Needles or prisms $(+\frac{1}{2}H_2O)$. Soluble in water. With iodine it forms a periodide $C_{21}H_{18}N_2(C_2H_5)I_3$ [123°].

Gives a strongly alkaline solution with Ag_2O which on neutralising with HCl and adding $PtCl_4$ gives a crystalline platino-chloride $(C_{23}H_{23}N_2Cl)_2PtCl_4$.

Methylo-iodide [209°]. Thin white needles.

Phenylene-benzaldehydine carboxylic acid

$C_{21}H_{16}N_2O_2$ *i.e.*



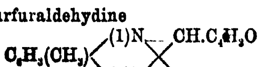
$$CO_2H.C_6H_3\left\langle\begin{matrix}(1)N\text{---}CH.C_6H_5\\ (2)N\text{---}CH.C_6H_5\end{matrix}\right.$$

Prepared by the oxidation of tolylene-benzaldehydine with $KMnO_4$. Is not altered by heating with HCl to 200°.

Salts: A'Ag: white precipitate. A'_2Ca: difficultly soluble needles.

Tolylene-furfuraldehydine

$C_{17}H_{14}N_2O_2$ *i.e.*



$$C_6H_3(CH_3)\left\langle\begin{matrix}(1)N\text{---}CH.C_4H_3O\\ (2)N\text{---}CH.C_4H_3O\end{matrix}\right.$$

[128½°]. Thin white prisms. Easily soluble in alcohol, ether, &c., with difficulty in cold ligroïn.

Preparation.—(1) By heating furfurol with *o*-tolylenediamine. (2) By adding furfurol (20 pts.) to a solution of *o*-tolylenediamine hydrochloride (20 pts.) in 80 pts. of water; on standing the hydrochloride separates out and is purified by crystallising the base repeatedly from ligroïn; yield 55 p.c. of the theoretical.

Salts: $B'HNO_3$: needles. $B'_2H_2SO_4$: prisms $(B'HCl)_2PtCl_4$: yellow crystals.

Methylo-iodide [195·5°]. Leaflets. Difficultly soluble in water; bitter taste; powerful poison.

Methylo-chloride: leaflets; easily soluble in water. Powerful poison.

Methylo-triiodide $C_{17}H_{14}N_2O_2(CH_3)I_3$ [126°–128°]. Light brown needles.

Methylo-pentiodide $C_{17}H_{14}N_2O_2(CH_3)I_5$ [109°]. Steel-blue pillars.

p-**ALDEHYDO-BENZOIC ACID** $C_8H_6O_3$ *i.e.* $C_6H_4(CHO)(CO_2H)$ [c. 246°]. Formed by careful oxidation of terephthalic aldehyde with chromic mixture (Löw, *A.* 231, 365; *B.* 18, 947). Needles (from water). Small needles when sublimed. M. sol. ether or chloroform, sl. sol. hot water.

Salt.—AgA'. *Ether.*—EtA'. Shows characters of benzoic aldehyde.

Reactions.—1. Does not reduce ammoniacal $AgNO_3$. Its ethyl ether, however, reduces ammoniacal $AgNO_3$.—2. Does not give Perkin's reaction with NaOAc and Ac_2O.—3. With $ZnCl_2$ and alcoholic $NPhMe_2$ it forms the zinc carboxylate of leuco-malachite green, [147°].

Phenyl hydrazide [226°].

p-*Aldehydo-nitro-benzoic acid*

$C_6H_3\overset{(2)}{(NO_2)}\overset{(1)}{(CHO)}\overset{(4)}{CO_2H}$. *Nitro-terephthalic-aldehyde-acid* [160°]. Large four-sided prisms. Easily soluble in alcohol and ether, sparingly in chloroform. Formed by nitration of *p*-aldehydo-benzoic acid.

With acetone it gives the indigo-reaction (Löw, *B.* 18, 948).

ALDEHYDO-CINNAMIC ACID *v.* CINNAMIC ACID.

ALDEHYDO-NAPHTHOL *v.* OXY-NAPHTHOIC ALDEHYDE.

ALDEHYDO-OXY ACIDS. Got by heating aromatic oxy acids with chloroform and aqueous NaOH (Tiemann a. Reimer, *B.* 9, 1268).

$$C_6H_4(ONa)CO_2Na + 3NaOH + CHCl_3 =$$
$$C_6H_3(COH)(ONa)CO_2Na + 3NaCl + 2H_2O.$$

The COH takes either *o* or *p* position towards the hydroxyl.

ALDEHYDO-OXY-BENZOIC ACIDS $C_8H_6O_4$.

m-**Aldehydo-salicylic acid**

$C_6H_3(OH)(CHO)(CO_2H)[1:4:2]$. [219°]. S. ·7 at 100°; ·038 at 25°.

Preparation.—Salicylic acid (14 pts.), NaOH (25 pts.), water (50 pts.) and chloroform (15 pts.), are boiled for some hours, the product dissolved in water, and acidified with HCl. A yellow pp. is formed and is extracted with ether. The ethereal solution is shaken with aqueous $NaHSO_3$; this solution, when boiled with dilute H_2SO_4, deposits a crystalline pp. consisting of the (1, 2, 6) acid; the (1, 4, 2) acid remaining in the solution, from which it may be extracted by ether (Tiemann a. Reimer, *B.* 9, 1268; 10, 1563).

Properties.—Long delicate yellowish needles. V. sol. ether or hot alcohol, v. sl. sol. chloroform.

action on the skin, affected the colour of many plants, and reacted with acids with effervescence and the production of new substances wherein neither the properties of the acids nor those of the alkalis were prominent. Van Helmont and his successors recognised two kinds of alkali, fixed and volatile; Duhamel, in 1736, divided fixed alkali into two classes, vegetable (potash), and mineral alkali (soda). Little or nothing was known regarding the composition of alkali until the year 1755, when Black (on the occasion of graduating as M.D. at Edinburgh) published his dissertation on 'Magnesia Alba, Quicklime, and other Alkaline Substances.' *Magnesia alba* dissolved in acids with effervescence; but after being strongly heated no effervescence attended the solution of this alkali. The notion of Basil Valentine (end of 15th and beginning of 16th century), that lime when burnt combined with 'matter of fire,' had been accepted by many as an explanation of the difference in the behaviour towards acids of burnt and unburnt lime. If this explanation applied to magnesia it should be possible perhaps to get hold of this 'matter of fire,' which combined with the *magnesia alba* when that body was heated. But Black found that a given mass of *magnesia alba* weighed more than the calcined magnesia obtained from it. Hence something was lost instead of gained during the process of heating. This something proved on further quantitative examination to be a gas different from common air; to it Black gave the name of *fixed air*. The effervescence or non-effervescence of alkalis with acids was proved by Black to accompany the presence or absence of fixed air (carbonic acid). From this time a distinction was clearly drawn between alkalis, which dissolved in acids without effervescence, and carbonated alkalis, the solution of which in acids was accompanied by the escape of carbonic acid gas. It was recognised that whether a caustic or a carbonated alkali were dissolved in an acid, the body which remained in solution, and which had no close resemblance either to the acid or the alkali, was one and the same.

The properties of the alkalis were supposed by the older chemists to be due to a 'principle of alkalinity,' or sometimes to a 'principle of saltness,' which latter principle was common to acids, alkalis, and the products of their mutual action, *i.e.* salts. Closely allied to, and sometimes regarded as identical with, the alkalis, was the group of earths. These bodies were known to neutralise acids and affect colouring matters like alkalis, but they were much less soluble in water than the alkalis. It was taught by some chemists that an alkali is hidden in every earth, and by others that an alkali is an earth refined by the presence of acid and combustible matter. Black's exact quantitative investigations tended to disparage all such explanations as these; but it yet remained to find the precise composition of the alkalis and the earths. Lavoisier thought that these bodies must be compounds; but, as he had no means of proving this, he classed them with the elements, while suggesting that the earths were probably compounds of oxygen with unknown metals. In 1807 Davy decomposed two alkalis, potash and soda, by passing an electric current through these substances when molten; and a year later he succeeded, by the same agency, in separating the earthy bodies lime, baryta, and strontia, into oxygen and, in each case, a metal.

The name alkali is now generally applied to the compounds of hydrogen and oxygen with one or other of the five metals, lithium, sodium, potassium, rubidium, cæsium (*v.* Alkalis, Metals of the); an aqueous solution of ammonia is also regarded as containing an alkali, viz. a compound of hydrogen and oxygen with the radicle *ammonium* (*v.* Ammonium compounds). The alkalis are classed with the hydroxides, *i.e.* compounds of hydrogen and oxygen with a third element, rather than with the hydrates, *i.e.* compounds of water with an oxide or a salt (*v.* Hydrates). The general formula of the alkalis is written MOH rather than M_2OH_2O; M = Li, Na, K, Cs, Rb, or NH_4. The alkalis are very soluble in water; these solutions neutralise acids forming salts, and also precipitate most of the heavy metals from their solutions in the form of oxides or hydrated oxides; aqueous solutions of the alkalis act corrosively on animal and vegetable substances, and also alter the tint of many colouring matters. When moist, the alkalis, with the exception of ammonia, readily combine with carbonic acid to form carbonates. Lithia is much less soluble in water than the other alkalis. The solid alkalis are not decomposed by the action of heat alone.

M. M. P. M.

ALKALI-BLUE *v.* Phenyl-rosaniline sulphonate of soda.

ALKALIMETRY.—The estimation of alkalis by volumetric methods, *v.* Analysis.

ALKALINE EARTHS, METALS OF THE.—Calcium, Strontium, Barium.—Certain substances, more or less alkaline in their properties, but differing from alkali chiefly in being insoluble in water, were known from early times; these substances were called earths. After a time some of the earths were found to dissolve in water, although to a less extent than alkalis; these comparatively soluble earths were separated from the others and classed together as the alkaline earths. The best known alkaline earth is lime; this substance was long considered identical with baryta and strontia, but in 1774 Scheele proved that baryta was different from lime, and in 1792 Hope distinguished strontia from the two other alkaline earths. After decomposing the alkalis potash and soda, Davy applied the agency of electricity to the three substances just named, and in 1808 he succeeded in separating each into oxygen and a metal. Davy made his experiments quantitative; he also synthesised the three alkaline earths from oxygen and the metals he had himself discovered; thus he proved the alkaline earths to be metallic oxides. The metals calcium, barium, and strontium were not obtained in a state of approximate purity until 1855. The metal magnesium is sometimes classed with calcium, barium, and strontium; but, on the whole, it seems better to place magnesium with zinc and cadmium (*v.* p. 114, also Magnesium Group of Metals).

Some of the principal data regarding the metals of the alkaline earths are presented in the following tables.

	CALCIUM	STRONTIUM	BARIUM
Atomic weights . .	39·9	87·3	136·86
No compounds gasified. Combining weights determined; and most probable formulæ of oxides and chlorides deduced from considering analogies with other oxides, &c. Molecular weights unknown.			
Melting points (data uncertain)	high red-heat above strontium	moderate red-heat above barium	below red-heat

	CALCIUM	STRONTIUM	BARIUM
Malleability, colour, &c.	Very ductile, but when hammered becomes brittle; whitish - yellow; hardness about same as lead.	Ductile and malleable; colour resembles calcium but clearer; harder than lead.	Somewhat ductile; gold-yellow colour.
Wave-lengths of most characteristic lines in spectra.	Ca_β (yellow) 5588. H (violet) 3969. K (do.) 3933·8.	Sr_δ (blue) 4604	Ba_γ (yellow) 5588.
Chemical properties.	Quickly oxidises in moist air; decomposes cold water rapidly; heated to redness in air, burns without smoke; readily combines with Cl, Br, I, P, and S, at high temperatures.	Closely resembles calcium; decomposes water more rapidly.	Resembles calcium; burns when heated in O – H flame.
Occurrence and preparation.	Very widely diffused in rocks, waters, plants, and animals, as carbonate, sulphate, phosphate, and silicate: prepared by electrolysis of mixture $CaCl_2$, $SrCl_2$, and NH_4Cl.	Not very widely diffused; occurs as carbonate and sulphate in rocks, and waters; prepared by electrolysis of fused $SrCl_2$.	Not very widely diffused; occurs as carbonate, sulphate, and silicate, in rocks, waters, and certain plants: prepared by electro- [illegible]is of $BaCl_2$ mixed [illegible] H_4Cl.

Un. affected the colour of many | molten; and a year later he succeeded

General Formula and Character of Salts.

MO, MO_2, MO_2H_2, MS, MS_2H_2, MX_2($X = Cl$, Br, I, F, CN), MSO_4, $M2NO_3$, MCO_3, &c., where $M =$ Ca, Sr, or Ba. MO_2 decomposed by heat. Salts for the most part white; no great tendency to form double salts; polysulphides known, $SrS_4 6H_2O$ and BaS_4H_2O, in definite crystals. Oxides and hydroxides markedly basic; latter, except that of Ba, decomposed by heat alone into oxides and water; almost all similar salts isomorphous; many salts isomorphous with corresponding compounds of Mg, *e.g.* carbonates; most, with corresponding compounds of lead; MO and MO_2H_2 not very soluble in water, solubility increases as atomic weight of metal increases; MCl_2 and MBr_2 easily soluble, solubility decreases as atomic weight of metal increases; $CaSO_4$ very slightly soluble (S. ·272 at 38°), $SrSO_4$ nearly insoluble (S. ·01 at 100°), $BaSO_4$ insoluble. $CaCO_3$ slightly soluble (S. 1·13 at 100°), $SrCO_3$ and $BaCO_3$ nearly insoluble. Nitrates all soluble, solubility decreases as atomic weight of metal increases; $Ca2NO_3$ S. 93·1 at 0°. $Sr2NO_3$ S. 54·9 at 10°. $Ba2NO_3$ S. 7 at 10°.

These data show that the metals of the alkaline earths differ from the alkali metals (compare data for latter on p. 115); the former are not so readily oxidised as the latter; the heats of formation of the oxides of the alkaline earth metals are smaller than those of the alkali metals; the hydroxides of the alkali metals cannot, but the hydroxides of the alkaline earth metals except that of Ba can, be separated into oxides and water by the action of heat alone. The alkali metals are specifically lighter than those of the alkaline earths; the composition of the oxides and chlorides of the former is represented by formulæ containing two atoms of metal to one of oxygen or two of chlorine, while that of the corresponding salts of the latter is represented by formulæ containing one atom of metal to one of oxygen or two of chlorine. The salts of the alkali metals, as a class, are much more soluble in water than those of the alkaline earth metals; the hydroxide, carbonate, and phosphate of lithium are, however, considerably less soluble than the corresponding salts of the other alkali metals (*v.* Alkalis, Metals of the, p. 115). Although magnesium forms the oxide MgO, the chloride $MgCl_2$, and the sulphate $MgSO_4$, salts analogous in composition to the oxides, chlorides, and sulphates of the metals of the alkaline earths, nevertheless this metal is clearly cut off from these by the following, among other, characteristics. The heats of formation, in aqueous solutions, (1) of the haloid salts of Ca, Sr, and Ba, (2) of Mg, Zn, and Cd, indicate the existence of two groups, in the first of which (Ca, Sr, Ba) the value of the reaction increases, and in the second of which (Mg, Zn, Cd) the value of the reaction decreases, as the atomic weights of the metals increase. The data are from Thomsen:

M	$[M,Cl^2,Aq]$	$[M,Br^2,Aq]$	$[M,I^2,Aq]$
Ca. . .	187,600	165,800	135,300
Sr. . .	195,700	173,800	143,400
Ba. . .	196,300	174,400	144,000
Mg . .	186,900	165,000	134,600
Zn. . .	112,800	90,900	60,500
Cd. . .	96,300	74,400	44,000

Magnesium is scarcely oxidised in ordinary air; it does not decompose cold water; nor does it combine so readily with the halogens as the metals of the alkaline earths do. The spectrum of magnesium, as produced in the electric arc, is marked by a series of triplets alternately sharply marked and diffuse, and diminishing in brightness towards the more refrangible side; the spectra of barium and strontium show no triplets, but a series of lines only; the spectrum of calcium is marked both by lines, perhaps homologous with those of barium and strontium, and also by well-marked triplets (Liveing and Dewar). Magnesium sulphate is very soluble in water; this salt, and also the carbonate and chloride, readily combines with salts of the alkali metals to form double compounds. Magnesium oxide is scarcely if at all soluble in water; the formation of the hydroxide by the action of water on the oxide is attended with the production of very little heat: $[MgO, H^2O] =$ (approx.) 3,000 (Thomsen).

The mutual relations of the two groups of elements—the alkaline earth metals and the magnesium metals—are suggested by the position they occupy in the classification based on the *periodic law* (*q. v.*; *v.* also Classification). Both belong to Group II.; but Ca, Sr, and Ba occur, along with Be, in even series, and Mg, Zn, and Cd, along with Hg, in odd series, of that group. The metal beryllium exhibits analogies both with the alkaline earth, and with the magnesium, metals; it is one of those elements called '*typical*' by Mendeléeff (*v.* Beryllium). For accounts of the metals of the alkaline earths and their binary compounds *v.* the articles Barium, Calcium, and Strontium; and for the other salts of the metals *v.* Carbonates, Nitrates, Sulphates, &c.

M. M. P. M.

ALKALIS, METALS OF THE. (Lithium, Sodium, Potassium, Rubidium, Cæsium.)—The history of the name *alkali* has been briefly traced in the article under that heading. The alkalis potash and soda were decomposed by Davy in 1807; lithia (discovered by Arfvedson in 1817) was decomposed by the same chemist about 1818; cæsia and rubidia were discovered by Bunsen and Kirchoff in 1860–61, rubidium being obtained in the same year by Bunsen, by electrolysing the chloride; approximately pure cæsium was not prepared until 1882, in which year Setterberg obtained the metal by electrolysing the double cyanide of cæsium and barium. The more important properties of these metals and of their principal salts are presented in the tables on the next page and page 116.

Thermal values of reaction with water.—When an alkali metal reacts with water an alkaline hydroxide is formed and dissolved, and hydrogen is evolved; thus:—

$$M_2 + xH_2O = 2MOHAq + (x-2)H_2O + H_2.$$

This reaction would be expressed in the notation of thermal chemistry thus:—

$$[M^2,2H^2O] = -2[H^2,O] + [M^2,O^2,H^2,Aq].$$

The value of $2[H^2,O]$ is 136,720 gram-units when H_2O represents 18 grams liquid water; when the value of $[M^2,O^2,H^2,Aq]$ considerably

M	$[M^2,O^2,H^2,Aq]$.
M = Li_2	234,900
Na_2	223,600
K_2	232,900

General formulæ and characters of salts.—M_2O, (M_2O_2, M_2O_4), MOH, M_2S, (M_2S_2, M_2S_4), MSH, MX(X = Cl, Br, I, F, CN), M_2SO_4, $MHSO_4$, MNO_3, M_2CO_3, $MHCO_3$, &c., where M = Li, Na, K, Rb, or Cs. No oxides or sulphides of Rb and Cs have been prepared in a state of purity. Li_2O is the only oxide, and Li_2S the only sulphide, of Li known with certainty. Na_2O_2 and K_2O_4 are very stable towards heat, but quickly decompose in moist air, giving off oxygen and forming NaOH and KOH. Salts for the most part white, and very soluble in water; but LiOH is much less soluble than the other hydroxides, and Li_2CO_3 and Li_3PO_4 than the other carbonates and phosphates—(Li_2CO_3, S. ·769 at 13°, S. ·778 at 100°; Li_3PO_4, S. ·04 at 18° [approx.].) Chlorides, except LiCl, form many double salts with chlorides of heavy metals, *e.g.* M_2PtCl_6, $SbCl_36MCl$, &c. Sulphates, except Li_2SO_4, form alums, also double salts with sulphates of magnesium group. Most salts are isomorphous, but some of the lithium salts are not strictly isomorphous with corresponding salts of the other metals; some compounds of silver and thallium are isomorphous with those of the alkali metals. All the metals of this group are electropositive towards any other elements; their oxides and hydroxides are strongly basic. The latter cannot be decomposed by heat alone into oxides and water. Lithium differs from the other members of the group in the comparative insolubility in water of its hydroxide, carbonate, and phosphate, in the non-formation of an alum, and in some other respects (compare heats of formation of analogous salts); this element serves to connect the group of the alkali metals with that of the metals of the alkaline earths in somewhat the same way as the latter group is connected with zinc and cadmium by the element magnesium (*v.* ALKALINE EARTHS, METALS OF THE). The metals copper and silver are to some extent connected with the alkali metals. Copper forms two series of salts represented by Cu_2O and CuO respectively; the former, so far as composition goes, are analogous to the alkali salts. They are, however, much more insoluble in water than these, and, with the exception of the iodide and cyanide and some double salts, are much less stable than the salts formed from the oxide CuO. The salts of silver, as a class, are much less soluble in water than those of the alkali metals; their composition is similar—Ag_2O, $AgNO_3$, Ag_2SO_4, &c.; some of them are isomorphous with corresponding sodium salts, *e.g.* Ag_2SO_4. Silver forms an alum, and its oxide is markedly basic.

The alkali metals are placed in Group I., according to the classification of elements based on the periodic law, and this group also contains the metals Cu, Ag, and Au. Li, K, Cs, and Rb belong to even series, and Na, Cu, Ag, and Au, to odd series, of Group I. There can be no doubt, however, that sodium is closely connected with the other alkali metals, and that the three heavy metals (Cu, Ag, Au) present only feebly marked analogies to each other, and to the metals of the alkalis. In considering the classification of elements which the periodic law presents, attention must be paid, not only to the group in which any given family of elements occurs, but also to the character of the elements which precede and those which follow the given family in the same series; the position of the family in the complete scheme must also be considered (*v.* PERIODIC LAW).

In some respects thallium exhibits a marked chemical resemblance to the alkali metals; it forms an oxide Tl_2O and a hydroxide TlOH, both of which dissolve in water, producing a strongly alkaline and basic liquid, marked by most of the properties which characterise aqueous solutions of soda and potash; it also forms salts—Tl_2CO_3, Tl_2SO_4, $TlNO_3$, &c.—which, as a class, are easily soluble in water, and many of which are isomorphous with the corresponding alkali salts. Some of the thallous salts, however, resemble those of lithium in being comparatively insoluble, *e.g.* TlCl and Tl_3PO_4. Thallium also forms an alum, and a double platinum chloride Tl_2PtCl_6. On the other hand, the metal itself differs much from the alkali metals; it is heavy, is not very easily oxidised, does not decompose water except at a red heat, and is much more electro-negative than the alkali metals. Thallium forms an oxide, Tl_2O_3, from which a series of salts—Tl_23SO_4, $TlCl_3$, &c.—is obtained; these salts exhibit analogies with those of the earth metals. The heats of formation of thallous oxide, hydroxide, and chloride, are much smaller than those of the alkali salts; Thomsen gives these numbers: $[Tl^2,O,Aq]=39,200$; $[Tl^2,O^2,H^2,Aq]=107,500$; $[Tl^2,Cl^2,Aq]=76,900$ (*v.* EARTHS, METALS OF THE, and THALLIUM).

	LITHIUM	SODIUM	POTASSIUM	RUBIDIUM	CÆSIUM
Malleability, colour, &c.	Silver-white; easily drawn into wire, but less tenacious than lead; very soft, may be welded at ordinary temperature; not volatile at red heat.	Silver-white; soft as wax at ordinary temperature; very ductile at 0°; can be distilled at red heat.	White; brittle at 0°, malleable at 5° or so, pasty at 15°: can be distilled at 700°-800°.	Silver-white; soft as wax at −10°.	Silver-white; soft at ordinary temperature.
Wave-lengths of most characteristic lines in spectra.	Li_α (red) 6705 (blue) 4602	D_1 (orange) 5895 D_2 (orange) 5889	(yellow) 5800 K_β (violet) 4044	Rb_γ (red) 7800 Rb_α (orange) 6297	Cs_β (blue) 4597 Cs_α (blue) 4560
Chemical properties.	Oxidises in ordinary air but not so rapidly or completely as other metals of the group; decomposes cold water rapidly but without itself melting; ignites at temperature much above its melting-point; readily combines with halogens and sulphur.	Oxidises rapidly in air; decomposes water rapidly; combines very energetically with halogens and sulphur, decomposes many haloid salts at high temperatures.	Oxidises very rapidly in air; decomposes water rapidly; combines with halogens and sulphur.	Oxidises in air so rapidly that usually takes fire; decomposes water most rapidly; burns brilliantly in vapours of halogens, sulphur, and arsenic.	Exceedingly easily oxidised. Properties not yet exactly studied. Most electropositive of all elements.
Occurrence and preparation.	Widely diffused in rocks, waters, plants, and some animal secretions; occurs as silicate and phosphate with other alkali metals; prepared by electrolysis of mixture of LiCl and NH_4Cl.	In large quantities as chloride, silicate, fluoride, nitrate, &c., prepared by deoxidising Na_2CO_3 by hot carbon.	In large quantities as nitrate, silicate, sulphate &c.; prepared as Na.	Very widely diffused, but in very small quantities; in most K and Na minerals; in waters; no special Rb mineral known; prepared as Na and K	As silicate in a rare mineral. In minute quantities in many rocks and waters; prepared by electrolysis of double cyanide of Cs and Ba using Al poles.

An aqueous solution of ammonia is strongly alkaline; when neutralised by acids salts are obtained which, as a class, closely resemble those of the alkali metals, with which they are, for the most part, isomorphous. These salts are considered to be compounds of the radicle ammonium (NH_4) with acid radicles; the general formulæ given for salts of the alkali metals apply to the ammonium salts if M be taken to represent NH_4. This radicle ammonium replaces the elements Li, Na, K, Rb, or Cs, in most compounds without altering the crystalline form, and without changing the chemical type, of these compounds. The salts of ammonium are, therefore, classed with those of the alkali metals. (For more details regarding the constitution of these salts, and for an account of their properties, see AMMONIUM COMPOUNDS.) For accounts of the individual alkali metals and their binary compounds, see the articles CÆSIUM, LITHIUM, POTASSIUM, RUBIDIUM, and SODIUM; and for the other salts of these metals see CARBONATES, NITRATES, SULPHATES, &c.

M. M. P. M.

ALKALIS, Action on Organic Compounds. The tendency of alkalis is to form salts. Thus they react with acids and other hydroxylic compounds by displacing the hydrogen by potassium or sodium (p. 53). Neutral substances are frequently saponified by alkalis, *i.e.* turned into salts. Saponification means soap-making; in the narrowest sense it means boiling a fat with potash or soda: $C_3H_5(OC_{18}H_{35}O)_3 + 3KOH = C_3H_5(OH)_3 + 3KOC_{18}H_{35}O$. In a broader sense it means the splitting up of any compound ether into its alcohol and its acid, whether by means of an alkali, an acid, or by water alone. In the broadest sense it means the conversion of a neutral substance into an acid or the salt of an acid. Alkalis saponify compound ethers, nitriles, amides, and amic acids. In the case of nitriles the reaction takes place as follows: $R.CN + KOH + H_2O = R.CO_2K + NH_3$. Alkalis act upon chlorinated or brominated substances with production of haloid salts: the reaction is either one of substitution; $CH_3Cl + KOH = CH_3.OH + KCl$: or else HCl or HBr is abstracted; $CH_2Br.CH_2Br + KOH = CH_2{:}CHBr + KBr + H_2O$. The latter equation represents the action of alcoholic KOH on chlorinated or brominated hydrocarbons. Hydrogen and halogen are always taken from contiguous carbon atoms. Alcoholic potash sometimes displaces halogen atoms by ethoxyl: $CH_2Cl.CO_2K + KOH + EtOH = CH_2(OEt).CO_2K + KCl + H_2O$. γ-Chloro-acids are converted by neutralisation with potash into lactones (*q. v.*). When the halogen is in place of hydrogen in the benzene nucleus, it cannot be turned out by aqueous potash unless a nitro-group is also present. Thus chloro-benzene is not affected by potash, while *o*- and *p*- chloro-nitro-benzenes are converted into nitro-phenols.

When phenol is boiled with chloroform and NaOHAq, oxy-benzoic aldehyde results (Tiemann a. Reimer's reaction): $C_6H_5ONa + 3NaOH + CHCl_3 = C_6H_4(ONa)COH + 3NaCl + 2H_2O$ (*B.* 9, 824).

By the same method the group CHO can be introduced into many derivatives of phenol (p. 109).

If tetrachloride of carbon be used instead of chloroform, carboxyl enters the phenol, forming a carboxylic acid: $C_6H_5ONa + 5NaOH + CCl_4 = C_6H_4(ONa).CO_2Na + 4NaCl + 3H_2O$. Alcoholic potash sometimes acts as a reducing agent (p. 99, l. 42).

Potash-fusion (*or soda fusion*).

1. Converts aromatic sulphonates into phenols:

$$C_6H_5.SO_3K + KOH = C_6H_5OH + K_2SO_3.$$

2. Displaces halogens by hydroxyl:

$$C_6H_4Cl.CO_2K + KOH = C_6H_4(OH).CO_2K + KCl.$$

However, owing to the high temperature required, a subsequent migration of the hydroxyl sometimes takes place. Thus when any halogen benzene sulphonate or halogen phenol is fused with potash at 235°–270°, resorcin is produced.
3. Converts carboxylates into hydrocarbons: $CH_3.CO_2K + HOK = CH_4 + CO_3K_2$. Soda-lime, lime, or baryta may also be used for this purpose.
4. Converts the higher fatty aldehydes and aromatic aldehydes into alcohol and salt of the acid: $2Ph.CHO + KOH = Ph.CO_2K + Ph.CH_2OH$. In other cases also, potash acts by oxidising one portion of the substance and reducing another. Thus glycerin distilled with potash gives (*a*) by reduction, propylene glycol, (*b*) by oxidation, potassic acetate and formate. Similarly anthraquinone sulphonate gives (*a*) by reduction, anthracene, (*b*) by oxidation, alizarin.
5. Splits up unsaturated acids at the point of non-saturation into two salts:

$$CH_3.CH{:}CH.CO_2H + 2KOH = 2CH_3.CO_2K + H_2.$$

6. Resins usually give *p*-oxy-benzoate protocatechuate, and phloroglucin.

ALKALOIDS.—The term alkaloid was first applied to any organic base. It is now usually restricted to organic bases that are of vegetable origin and produce marked toxicological effects. Thus such bodies as ethylamine, asparagine, and leucine, are not usually classed as alkaloids. All the alkaloids contain nitrogen, and all except coniine, nicotine, and sparteïne contain oxygen. These three alkaloids are volatile, the others are fixed. The vegetable alkaloids are ammonia-, not ammonium-, bases, that is, they combine with HCl without elimination of H_2O. The following alkaloids have been described:

From *Achillea Moschata*: achilleïne, moschatine.

From *Aconitum Napellus, ferox, &c.*: aconitine, picro-aconitine, pseudo-aconitine, japaconitine, lycaconitine, myoctonine.

From *Æthusa Cynapium*: cynapine.

From *Agaricus*: agarythrine.

From *Alstonia constricta*: alstonine, porphyrine, alstonidine, alstonicine.

From *Arariba rubra*: aribine.

From *Artemisia abrotanum*: arbrotine.

From *Aspidosperma*: aspidospermine, aspidospermatine, aspidosamine, hypoquebrachine, quebrachine, quebrachamine, paytine, paytamine.

From *Angustura bark*: cusparine, gasipeïne.

From *Atherosperma*: atherospermine.

From *Atropa*: atropine, hyoscyamine, hyoscine, belladonine.

From *Baccharis*: baccharine.

From *Baptisia tinctoria*: unnamed.

From *Bebeeru*: beberine.

From *Berberis*: berberine, oxyacanthine, hydrastine.

From *Buxus*: buxine, buxidine.

From *Calabar beans*: physostigmine or eserine.

From *Capsicum*: capsicine.

From *Cannabis indica*: an unnamed alkaloid (M. Hay, *Ph.* [3] 13, 998).

From *Chelidonium*: chelerythrine, chelidonine.

From *Cinchona*: quinine, cinchonine, conquinine, quinicine, homoquinine, hydroquinidine, cinchonidine, aricine, cusconine, cusconidine, cincholine, cuscamine, cuscamidine, quinamine, cinchamidine, cinchotine, hydrocinchonine, con-quinamine, hydroquinine, dicinchonine, diconquinine, javanine, paricine.

From *Coca leaves*: cocaïne, ecgonine, hygrine.

From *Cocoa beans*: theobromine.

From *Coffee berries*: caffeïne.

From *Colchicum*: colchicine.

From *Conessi bark*: conessine.

From *Conium*: coniine.

From *Corydalis*: corydaline.

From *Crossoptera*: crossopterine.

From *Curare*: curarine.

From *Cytisus*: cytisine.

From *Delphinium*: delphinine, delphinoidine, delphisine, staphisagrine.

From *Dita bark*: ditamine or ditaïne, echitamine, echitenine.

From *Duboisia*: duboisine or hydrocyamine.

From *Ergot*: ergotine.

From *Erythrophleum*: erythrophleïne.

From *Esenbeckia*: esenbeckine.

From *Fraxinus americana*: an unnamed alkaloid (F. B. Power, *Ph.* [3] 12, 812).

From *Fumaria*: fumarine.

From *Gelsenium*: gelsenine.

From *Geselmium*: geselmine.

From *Glaucium*: glaucine, glaucopicrine.

From *Harmala*: harmaline, harmine.

From *Humulus lupulus* (*Hops*): lupuline (hopeïne), neurine.

From *Hymenodictyon*: an unnamed alkaloid.

From *Ipecacuanha*: emetine.

From *Isopyrum*: isopyrine, pseudo-isopyrine.

From *Lobelia*: lobeline.

From *Lotur bark*: loturine, colloturine, loturidine.

From *Loxopterygium*: loxopterygine.

From *Lupinus*: lupinine, lupinidine.

From *Lycopodium*: lycopodine.

From *Macleya*: mackleyine, sanguinarine.

From *Menispermum*: menispermine.

From *Mustard*: sinapine.

From *Nicotiana tabacum*: nicotine.

From *Nymphæa alba*: an unnamed alkaloid (Grüning, *B.* 16, 969).

From *Oleander*: oleandrine.

From *Opium*: morphine, codeïne, thebaïne, papaverine, narcotine, narceïne, hydrocotarnine, pseudomorphine, codamine, laudamine, laudanosine, meconidine, lanthopine, protopine, cryptopine, crytopine, oxynarcotine.

From *Papaver rhœas*: rhœadine.

From *Papaver somniferum*: *v.* OPIUM.

From *Pennius*: boldine.

From *Piper nigrum* (*Pepper*): piperine.

From *Pereiro bark*: geissospermine, pereirine.

From *Pilocarpus leaves*: pilocarpine, jaborine, pilocarpidine.

From *Pomegranate bark*: pelletierine.

From *Poppy*: rhœadine. *Opium Poppy v. Opium.*

From *Ratany root*: ratanhine.

From *Ricinus* (castor-oil plant): ricinine.

From *Salamandra*: samandrine.

From *Saphora*: saphorine.

From *Sinapis*: sinapine.

From *Spartium*: sparteïne.

From *Strophantus*: strophantine.

From *Strychnos*: strychnine, brucine.

From *Thalictrum*: thalictrine.

From *Taxus*: taxine.

From *Tea leaves*: caffeïne.

From *Tobacco*: nicotine.

From *Trigomella*: trigomelline, neurine.

From *Veratrum*: veratrine, veratridine, cevadine, cevadilline, jervine, rubijervine, pseudojervine, veratralbine.

From *Vetch*: vicine.

Formation of alkaloids in plants. Most of the above alkaloids are pyridine derivatives. They are probably produced by the action of ammonia or amido compounds upon non-nitrogenous bodies. Pechmann a. Welsh (*B.* 17, 2384) consider that the non-nitrogenous bodies are such acids as meconic, chelidonic, and cumalic, which are probably furfurane derivatives. These three acids are converted by ammonia into oxypyridine carboxylic acids. Cumalic acid is formed artificially from malic acid by action of conc. H_2SO_4; and it is probable that the two other acids are also formed by condensation of simpler acids.

V. Meyer has suggested that hydroxylamine by acting upon aldehydes may also play some part in the production of the nitrogenous constituents of plants.

Extraction: The tissue is extracted with dilute acid and the extract ppd. by ammonia, potash, soda, lime, or magnesia. Volatile alkaloids are then distilled, fixed alkaloids are crystallised from a suitable solvent. The extraction of alkaloids from animal matter, as in cases of poisoning, is described in the next article.

Reactions.—1. *Sodic phosphomolybdate* added to solutions acidified with nitric acid gives, in the cold, a yellowish-white flocculent pp. Aniline, the alkylamines, and quinoline, as well as silver, mercurous, and lead, salts are also ppd. by this reagent (Sonnenschein, *A.* 104, 45). To recover the alkaloid, the pp. is boiled with baryta, when volatile alkaloids distil over. The residue is saturated with CO_2, evaporated to dryness and extracted with alcohol. Sonnenschein's reagent is prepared by dissolving yellow ammonic nitro-molybdate in Na_2CO_3Aq, drying and strongly heating; if reduction of molybdic acid take place, the product is moistened with HNO_3 and again heated. It is then heated with water, nitric acid is added, and the liquid diluted until 10 parts of the solution contain 1 part of solid residue.

2. *Phosphotungstic acid* may be used instead of phospho-molybdic acid (Scheibler, *Fr.* 12, 315; *J.* 1860, 157). The reagent, which is a mixture of sodic tungstate and phosphoric acid, is added to solutions acidified with H_2SO_4. *Phospho-antimonic acid* got by dropping antimonic chloride into aqueous phosphoric acid, precipitates morphine, narcotine, and nicotine, but not atropine (F. Schulze, *A.* 109, 177).

3. *Potassio-mercuric iodide* produces flocculent yellowish-white pps., insoluble in acids and in dilute alkalis, slightly soluble in excess of the reagent, easily soluble in alcohol, and generally also in ether (F. Mayer, *J.* 1863, 708; *A.* 133, 236; De Vrij, *J.* 1867, 602). Theobromine, caffeïne, glucosides, carbohydrates, and organic acids give no pp. with Mayer's solution. Albuminous and gelatinous substances, in presence of free acid (but not in alkaline solutions) give sticky pps. (Valser, *Fr.* 2, 79). To separate the alkaloid from the pp., the latter is triturated

with $SnCl_2$ and excess of aqueous KOH; this reduces the mercury to the metallic state, and the base is then extracted by its proper solvent.

Mayer's solution contains 13·5 g. mercuric chloride and 49·8 g. potassic iodide per litre.

4. *Potassio-bismuthous iodide* is prepared by dissolving $Bi(OH)_2NO_3$ (80 g.) in HNO_3 (200 c.c. of S.G. 1·18) and adding a conc. solution of KI (272 g.). The solution is cooled until KNO_3 crystallises, and the mother liquor is then diluted to a litre (Dragendorff, *Fr.* 5, 406; Kraut, *A.* 210, 310). The solution is added to the alkaloid dissolved in dilute H_2SO_4 or HI. Double iodides of the alkaloid and of bismuth are ppd. The alkaloid can be recovered by decomposing these double iodides with aqueous NaOH, and extracting with a proper solvent.

5. *Potassio-cadmic iodide* forms white flocculent pps. when added to solutions of alkaloids acidulated with H_2SO_4. The pps. soon become crystalline; they are soluble in alcohol, insoluble in ether. They dissolve in excess of the reagent. The alkaloid can be recovered by treatment with NaOHAq and a solvent (Marmé, *Bl.* [2] 9, 203).

6. *Potassio-platinic iodide* and *potassio-auric iodide* also pp. alkaloids (Selmi, *G.* 5, 255). These solutions are prepared by adding KI to solutions of $PtCl_4$ or $AuCl_3$ until the pp. first formed is redissolved. The platinum salt gives, in acetic acid solution, a black pp. with nicotine, but none with conessine; it also gives a wine-red pp. with solanidine but none with solanine. The gold salt gives, on evaporation, arborescent crystallisation with nicotine, but only oily drops with coniine.

7. A solution of iodine (1 pt.) in KI (1 pt.) dissolved in water (100 pts.) gives brown, often crystalline, pps. of the periodides. These polarise light like tourmaline. The alkaloids can be recovered by treating the pp. with SO_2Aq.

8. Animal charcoal removes most of the alkaloids from aqueous solution. The alkaloid can then be extracted from the charcoal by a suitable solvent (Graham a. Hofman, *C. J.* 5, 173).

9. *Picric acid* pps. many alkaloids, even in presence of a large excess of H_2SO_4. Morphine, caffeïne, and glucosides are not so ppd. The reagent pps. English but not German preparations of atropine (Hager, *Fr.* 9, 110).

10. *Tannin* gives a white or yellowish-white pp. The salts of morphine, with the exception of the acetate in strong solution, are not ppd. by tannin. The alkaloids can be recovered by treating the pp. with lime.

11. *Platinic chloride* gives, in conc. solutions, a yellowish-white or yellow pp. *Chloride of gold* does the same (*cf.* Coninck, *Bl.* [2] 45, 131).

12. *Sodic nitroprusside* usually forms oily drops of the nitroprusside, which crystallises on standing (Horsley, *C. N.* 5, 355; E. W. Davy, *Ph.* [3] 11, 756).

13. The *electrolysis* of solutions of salts of alkaloids has been studied by Bourgoin (*Bl.* [2] 12, 438).

14. The alkaloids are ppd. by sodium salts of *glycocholic*, *hyoglycocholic*, and *taurocholic acids*. The pps. appear to be acid salts of the alkaloids (W. F. de l'Abre, *C. C.* 1872, 231).

15. *Hydric sulphide* passed into alcoholic solutions of alkaloids forms compounds containing sulphur (Palm, *J.* 1863, 433; E. Schmidt, *B.* 8, 1267).

16. The *absorption-spectra* of various alkaloids have been mapped by A. Meyer (*P.* [3] 13, 413).

17. A solution of *iodine monochloride* in HCl added to a solution of an alkaloid in HCl gives a pp., usually yellow and sparingly soluble (Tilden, *C. J.* 21, 145; Dittmar, *B.* 18, 1612; Ostermayer, *B.* 18, 2298). According to Dittmar, if the alkaloid contain one pyridine ring, the pp. is of the form XICl; if it contain two pyridine groups it is of the form YI_2Cl_2. However, NEt_4Cl, NEt_3HCl, caffeïne hydrochloride, and pyrrol, all give pps. though they contain no pyridine ring, while *B*-oxy-quinolines, and tetra-hydroquinoline give no such pps. The pps. may also be got by using a mixture of KI, KNO_2, and HCl, instead of ICl. The chloro-iodides are converted by excess of chlorine into unstable compounds $XICl_3$. Ammonia converts the chloro-iodides into iodo-amides, $XINH_2$; these are dark-green or dark-red unstable bodies, insoluble in water, but converted back into the chloro-iodides by HCl, and decomposed by boiling with alcohol according to the equation:

$$6XINH_2 = 3X + 3XI_2 + 4NH_3 + N_2.$$

These iodo-amides are also produced by the combination of the alkaloids with iodide of nitrogen.

Tests for alkaloids.—The above reactions are general. The following tests may be used in distinguishing the alkaloids from one another:—1. The alkaloid is *sublimed*. Sublimation begins below 100° in the case of caffeïne, theobromine, and cantharidine; between 150°-200° in the case of strychnine, morphine, and pilocarpine (Wynter Blyth, *C. J.* 33, 318). The following give no sublimate, but melt: (*a*) below 100° hyoscyamine, atropine; (*b*) between 100°-150° papaverine; (*c*) above 200° solanine. The sublimate is then examined microscopically (Helvig, *Fr.* 3, 43; Deane a. Brady, *C. J.* 18, 34).—2. Conc. H_2SO_4 produces colours with certain alkaloids, *e.g.* a blood-red colour with thebaïne and a crimson with veratrine.—3. Nitric acid usually produces a yellow solution, but morphine and brucine give a red colour.—4. Sulphuric acid containing a little molybdic acid, so-called sulphomolybdic acid, gives a violet colour with morphine, and characteristic colours with other alkaloids.—5. Erdmann's solution is prepared by adding HNO_3 (6 drops of S.G. 1·25) to water (100 c.c.) and adding ten drops of the diluted acid to 20 c.c. of conc. H_2SO_4. This solution gives a blue colour when warmed with solutions of codeïne, and characteristic colours with other alkaloids.—6. Chlorine water, followed by ammonia, gives a green colour with quinine, a red colour with narceïne, and an orange colour with narcotine.—7. A mixture of an alkaloid (1 pt.) with sugar (7 pts.) often gives colours with conc. H_2SO_4. Morphine and codeïne give a purple, aconitine a rose-red (R. Schneider, *P.* 147, 128).—8. H_2SO_4 and a little Ce_2O_3 give with strychnine a fine blue colour; with brucine, orange; narcotine, brown, cherry-red, finally wine-red; morphine, olive-brown, finally brown; codeïne, olive green, finally brown; quinine, pale yellow; cinchonine and caffeïne, no colour; veratrine, atropine, solanine, emetine, brown; colchicine, green becoming brown; papaverine, almost black (Sonnenschein, *B.* 8, 632).

Optical Properties.—When the solution of an alkaloid affects a ray of polarised light the specific rotatory power of solutions of its normal salts is independent of the nature of the acid if the alkaloid is mono-acidic and the salt is not decomposed by water, but if the alkaloid is di-acidic the basic salts usually rotate much less than the normal salts (Oudemans, *R.* 1, 18).

ALKALOIDS, CADAVERIC *v.* PTOMAÏNES.

ALKALOIDS, POISONOUS, Detection and Estimation of.—This article will be directed to the simple detection of the chief alkaloids; but incidentally their quantitative estimation will be touched upon. The detection and complete recognition of an alkaloid by chemical tests is often a matter of great difficulty, even in the case of some well-known and potent alkaloids. Indeed, in some cases these difficulties are at present insurmountable by chemical means alone, and physiological experiments have to be called in aid. The obstacles to the recognition of these bases, when several are present, is still greater. Indeed, it may be stated that the complete separation of a mixture of commonly occurring alkaloids is a problem still awaiting solution. The toxicologist has too often to content himself with the identification of one or two alkaloids in organic mixtures, and the determination of their aggregate quantity, being unable to ascertain their individual amounts.

History.—The earliest methods devised for the detection of alkaloidal poisons in forensic research were those found effective for the separation of the vegetable alkaloids from the other matters with which they are found associated in nature; and modifications of these methods are even now employed for this purpose. The material to be operated on was extracted with diluted acids, aided by gentle heat, gummy and other substances removed by lead acetate, the excess of lead ppd. with hydrogen sulphide, and the alkaloid obtained as a salt—generally an acetate—in a greater or less degree of purity by evaporation of the solution. This and other crude processes were mostly abandoned when Stas (*A.* 84, 379) published his classical paper on the separation of alkaloids from organic mixtures, and devised a new and refined process, which was subsequently modified and improved by *Otto* (*A.* 100, 39), Dragendorff (*Gerichtl. chem. Ermit. v. Gift.*, 1876), and others. In one form or another, this process, generally known as that of Otto-Stas, is still the one most generally employed in forensic analyses, though Sonnenschein (*A.* 105, 45), Selmi (*C. J.* 1877, 93), and more recently L. Brieger (*Die Ptomaïne*, Pt. I., 1885; Pt. II., 1885; Pt. III., 1886) have each employed different but less refined methods for the general separation of the organic bases from the matters with which they are commonly associated.

Methods of Procedure.—If an apparently fairly pure solid body has to be examined, *e.g.* a crystalline medicinal powder, its alkaloidal nature may be demonstrated by ascertaining in the ordinary way that it contains both organic carbon and nitrogen; by its sparing solubility in aqueous alkaline, and its ready solubility in aqueous acid, solutions; and by adding to the acid solution reagents that react with the alkaloids as a class. The alkaloid will usually be ppd. from its acid or aqueous solution, if this be not too dilute, by caustic and by carbonated alkalis; and will appear either in the form of oily droplets (liquid and volatile alkaloids), or as an amorphous pp., becoming crystalline on standing. If the pp. redissolves in excess of the caustic alkali, as in the case of morphine, it will again separate when the alkali becomes carbonated, as by exposure to the air. Since none of the alkaloids are altogether insoluble in water, no pp. may form in very dilute solutions, and yet an alkaloid be present. There are, however, certain group reagents that pp. the alkaloids from their barely acid solutions, even when these are highly dilute; and these reagents are generally employed where the presence of an alkaloid is suspected. Such general reagents are the following; but it must be borne in mind that as any one of them may fail to give a precipitate with a given organic base, two or more of them must be used, under appropriate conditions, in order to prove or disprove the presence of an alkaloid in the solution to be tested.—1. A weak solution of *iodine in potassium iodide.* This reagent gives a more or less coloured pp. with extremely dilute solutions of most of the vegetable alkaloids.—2. *Bromine water* yields similar pps., but has the disadvantage of yielding pps. with the phenols also.—3. *Tannin* pps. most of the vegetable alkaloids from their not too dilute solutions.—4. *Mercuric chloride* in aqueous, and also in alcoholic solution, is a valuable pptant., and is especially useful in the separation of the organic bases resulting from putrefaction (*ptomaïnes*), for the separation of which the Otto-Stas method to be presently described is inadequate (L. Brieger, *op. cit.*).—5. *Potassio-mercuric iodide* solution is perhaps the most generally useful pptant. of the alkaloids; and from the ppts. thus produced the alkaloids may be recovered in a high state of purity by trituration with stannous chloride and solution of NaOH, and extraction of the alkaloid thus liberated, with ether.—6. *Phosphomolybdic acid* in nitric acid solution pps. the alkaloids from acid solutions. The alkaloids may be recovered from these pps. by decomposing them with barium hydrate, and either distilling off the alkaloid (volatile alkaloids), or after removing the baryta by means of a stream of carbon dioxide, subsequently extracting the alkaloid with absolute alcohol.—7. *Picric acid* is also a useful pptant., and from the pps. thus produced the alkaloids may be separated by acidification with HCl and agitation with ether.—Many other general pptants. of the alkaloids have been proposed, but the above fulfil almost every useful purpose; and on the ppn. of organic natural bases by alkalis, and their resolution and extraction by ether and other special solvents—or on their removal from organic solutions by one or other of the above pptants.—are based the most approved general methods for the separation of the poisonous alkaloids in forensic analysis.

The method most generally employed for the extraction of the vegetable alkaloids from admixture with animal matters is that originally devised by Stas for the separation of nicotine in he course of a forensic analysis, and now known with modifications as the Otto-Stas method. The writer of this article has introduced further modifications which are embodied in the following description, and have been found by him necessary in those cases where unstable and easily hydrolysed alkaloids are to be sought for, such as morphine, which is readily decomposed by heating its acidified solutions, and aconitine, which is unstable in alkaline and especially in ammoniacal solutions. In all cases the method, which is a quantitative one, is greatly dependent for success upon the care with which the preliminary operations are conducted.

The organic material to be operated upon, if solid, is brought into as minute a state of division as its nature permits, and is then digested with twice its weight of rectified spirit of wine at a temperature of about 35°. Liquids are also treated with twice their volume of rectified spirit. Redistilled methylated spirit of wine may be used for these operations. After several hours' digestion the liquid is poured off from the deposited solids, and the digestion is repeated with a fresh quantity of spirit. This is again poured off, and mixed with the previous alcoholic infusion. If solid matter, *e.g.* liver, is operated on, the liquid is squeezed from the solid portion at each digestion in a piece of fine cambric which acts as a crude filter; and the liquids thus obtained are added to the other alcoholic liquids. After two or more digestions, according to the nature of the organic matter, the undissolved portions are subjected to a new digestion, also at 35°, with spirit faintly acidified with acetic acid. Some recommend tartaric in preference to acetic acid, but this is objectionable, when, as is usually the case, morphine has to be sought for: others use oxalic acid, but this acid may have to be sought for as well as the alkaloids. Enough acid must be added to keep the liquid just perceptibly acid, excess being avoided. After a prolonged digestion with the acidified alcohol, this is poured off, the solids squeezed, and the digestion repeated, but this time with unacidified spirit. A final digestion may be required, the rule being to continue the exhaustion with spirit of wine so long as any colour is imparted to this. The alcoholic liquids obtained before acidification after mixing are momentarily and rapidly raised to a temperature of 70°, cooled, and the insoluble residue filtered and washed with spirit; and those obtained with and after the use of acetic acid are similarly treated. But the two liquids, the unacidified and the acidified are not mixed till a later stage is reached. In this way, by keeping the liquids separate, danger of hydrolysation of unstable alkaloids is as far as possible avoided. The alcoholic infusions are now evaporated at a temperature never exceeding 35° to the consistency of a syrup. It is advisable during the course of the evaporations to neutralise a portion of the free acid with caustic soda from time to time, so as to keep the liquids just perceptibly acid. The evaporations are easily effected with tolerable rapidity by placing the liquids in shallow basins supported on large beakers some inches above the floor of an ordinary oven, which is heated by a gas flame playing on the top. The door is kept a little ajar. The advantages of this arrangement of the author's are, that overheating is avoided, evaporation is more rapid than by any other method, and all creeping of the liquids up the sides of the basins is obviated. This course of procedure is greatly preferable to distilling off and recovering the alcohol, as usually recommended. The syrupy liquid is now drenched with about 30 c.c. of absolute alcohol, with constant stirring or grinding in a mortar; the alcohol is poured off from the pasty mass which usually separates, and replaced by successive quantities of 15 c.c. alcohol so long as a colour is imparted to this. The alcoholic liquids are mixed, filtered, the filter washed with alcohol, and the filtrate evaporated in the oven, as before, at a temperature not exceeding 35°. The syrupy residues—that from the plain and that from the acidified spirit of wine—are diluted with a small quantity of water, filtered, the filters washed with water, and the filtrates mixed. They should, together, measure 15–20 c.c. The liquid is introduced into an accurately stoppered tube, partially neutralised, if necessary, with caustic soda, taking care, however, to leave it slightly acid. If the method laid down has been scrupulously followed, we have now a liquid containing the whole of the alkaloids, and free from albuminoids. The aqueous and faintly acid liquid in the tube is now covered with twice its volume of washed ether, and the whole is mixed by gently and repeatedly inverting the tube, care being taken not to emulsify the mixture by any violent agitation. The ether is allowed to separate, and this is favoured by giving an occasional sharp rotatory shake to the tube. The supernatant ether is then pipetted off, and replaced by a new and smaller quantity of ether. The tube is again shaken; and the operation of extraction with ether is continued till a few drops on evaporation leave no residue. Four or five extractions will generally suffice. The ethereal solutions as they are pipetted off are successively washed by vigorous shaking in a second stoppered tube with 5 c.c. water to which a few drops of dilute sulphuric acid have been added. The ether on evaporation may yield an oily residue which may be reserved for further examination and for physiological tests. But the acid liquid subjected to ethereal extraction will still contain nearly all the alkaloids, as the acid salts of these are mostly practically insoluble in ether; but the salts of some of the alkaloids being perceptibly soluble in ether may be met with in the 'acid-ether' extract. The acid aqueous solution, and the acidulated water with which the ether has been washed, are mixed, alkalised with sodium carbonate, and again exhausted four or five times as before with washed ether; only in this case the first exhaustion is made with a mixture of 1 vol. chloroform and 3 vol. ether, and the final extractions with ether alone. These successive ethereal extracts are washed in a tube by shaking anew with 5 c.c. water. They are then transferred to a third and finally to a fourth tube, the first containing 10 c.c. water acidulated with a few drops of sulphuric acid, and the last containing 5 c.c. water alone, and agitated. By these operations the alkaloids are first liberated from their salts by the alkali, then transferred to the ether-chloroform in which they are soluble; then again converted into sulphates, which, being insoluble in ether and chloroform, again pass into the acid solutions, impurities being left behind in the ether. We have now again the alkaloids in acid solution, but in a much purer state than before. The acid liquid and the final wash-water are mixed, washed with a little ether once or twice, then re-alkalised with sodium carbonate, and well re-extracted with chloroform-ether and ether. These ethereal solutions are washed with water barely alkalised with sodium carbonate, then filtered through a dry filter, and evaporated to dryness in the oven below 35° in tared glass basins about eight centim. in diameter. Once dry, the residue may be transferred for a few minutes to the water-oven, dried at 100°, and weighed after cooling over sulphuric acid. This weight fairly represents that of the alkaloids. It is well before evaporating the bulk of the solution to evaporate a few c.c. only; if an oily odorous residue be left the presence of a volatile alkaloid is indicated; the evaporation is then modified by mixing the ether-chloroform with so much ether previously acidulated by agitation with a strong solution of hydrochloric acid as is necessary to render it acid. In this case it is not the free alkaloids, but their non-volatile hydrochlorides which are left and weighed. The residue may therefore be dissolved in water and subjected to appropriate tests—first for the alkaloids generally (*vide ante*), and secondly specifically for the volatile alkaloids. But if the solid free alkaloid has been obtained it must first be converted into a hydrochloride by moistening it with a very slight excess of very dilute hydrochloric acid, and evaporating to dryness *in vacuo* over sulphuric acid. The residue may then be dissolved in water and subjected to tests, which may be obtained from the ethereal extract either before or after conversion into hydrochloride and solution of this in water.

Morphine is practically insoluble in ether except immediately after ppn. from its solutions, hence if this alkaloid were present in the matters submitted to examination, but little of it would be removed by the chloroform and ether, more especially if, as is advisable, the agitation with these solvents was not executed immediately after the addition of sodium carbonate. In order to obtain the morphine, the *first* alkalised solution from which the other alkaloids have been removed must be re-extracted a few times with a well-washed mixture of equal volumes of acetic ether and ethyl ether, which is preferable to amyl-alcohol, and in which mixture morphine is soluble. The mixed ethers are washed with a little water, filtered through a dry filter, and evaporated just as the chloroform-ether was evaporated for the other alkaloids. The residue is usually not pure morphine, as acetic ether takes up other non-alkaloidal bodies, but these do not usually interfere with the morphine reactions.

G. Dragendorff (*Gerichtl. chem. Ermit. v. Gift.*, 1876, p. 141) has devised a process which proceeds upon the same general lines as that of Stas, but is much more elaborate. It requires, moreover, a higher temperature for the preliminary evaporation. The finely divided substance, if solid, is digested for several hours at a temperature of 40°-50° with dilute sulphuric acid—about 2 p.c. by volume of the acid. Liquids are acidulated with the same proportion of acid. The digestion is continued for several hours, and the mixture is then pressed, and filtered. The operation of extraction with dilute sulphuric acid is repeated two or three times, 100 c.c. of liquid being a convenient quantity for each extraction. The mixed filtrates, containing the alkaloids, are partially neutralised with magnesia, and carefully evaporated to a syrup at a temperature much below 100°; but never to dryness. It is certain that in this operation some alkaloids may be destroyed, and it is also asserted that basic bodies are formed by the decomposition of the albuminoids. A useful modification (L. Brieger, *op. cit.*) is to partially neutralise the liquid from time to time during the course of the evaporation, so that it is never more than very slightly acid in its reaction to litmus. The syrupy residue from the evaporation is mixed with three or four times its volume of rectified methylated spirit of wine, and a few drops of sulphuric acid, and allowed to digest at about 30° for twenty-four hours. The insoluble matter is separated by filtration and washed with spirit, and the filtrate and washings are distilled in a retort so as to recover the alcohol. The aqueous residue in the retort is diluted with water to 50 c.c., filtered, and introduced into a stoppered tube and exhausted successively with petroleum ether, benzene, and chloroform, 20-30 c.c. of each at a time, in the manner in which exhaustions are made with ether in Stas's process. The aqueous solution is then made alkaline with ammonia, and again exhausted successively with petroleum-spirit, benzene, chloroform, and amyl-alcohol. On evaporation of the respective solvents (consult what has been said under Stas's process as to volatile alkaloids) alkaloidal residues are obtained, which when taken up with water, either with or without previous conversion into hydrochlorides as necessity demands, may be submitted to appropriate tests for the alkaloids, and specially for the various suspected alkaloids.

Among the commoner alkaloids, and poisonous neutral substances:—

Petroleum ether removes from the acid aqueous solution:—some piperine, resins such as capsicin, camphor, and phenol.

Benzene further removes from the acid solution:—more piperine, caffeïne, colchicine, santonin, digitalin, cubebin, colocynthin, aloetin, picric acid, elaterin, and cantharidin.

Chloroform, again, removes from the acid aqueous solution: — cinchonine, theobromine, papaverine, narceïne, jervine, more digitalin, picrotoxin, smilacin, and senegin.

On rendering the solution alkaline with ammonia:—

Petroleum spirit removes from the alkaline solution:—strychnine, brucine, quinine, veratrine, aconitine, emetine, and the volatile alkaloids coniine, nicotine, lobeline, and trimethylamine (from putrefaction), the pimento-alkaloid, and aniline. If the presence of aconitine or emetine be suspected, the operation must be performed quickly, since these alkaloids rapidly decompose in alkaline solutions.

Benzene further removes from the alkaline solution:—atropine, hyoscyamine, physostigmine (eserine), thebaïne, codeïne; narcotine, and additional quantities of strychnine, brucine, quinine, cinchonine, veratrine, aconitine, and emetine.

Chloroform, again, removes from the alkaline solution:—some morphine, and additional quantities of cinchonine, narceïne, and papaverine.

Amyl-alcohol finally removes from the alkaline solution:—morphine, narceïne, and some neutral bodies, such as salicin.

Not all the substances enumerated above are poisonous; but they are bodies that may be present in medicinal mixtures, and hence are likely to come under the notice of the toxicologist in forensic analyses.

Selmi proposed another method of extracting the poisonous alkaloids, and applied it to the extraction of the ptomaïnes (*G.* 6, 153; *C. J.* 31, 93). The viscera are exhausted with alcohol and dilute sulphuric acid. This acidified alcoholic extract is filtered and evaporated at a temperature of 65°, again filtered, and evaporated to a syrup. The residue is taken up with water, filtered, the filtrate treated with basic lead acetate, and the mixture exposed to the air for twenty-four hours. It is then filtered, the excess of lead removed by hydrogen sulphide gas, and the filtrate concentrated. This is then repeatedly extracted with ether. The ethereal solution is then saturated with a stream of dry carbon dioxide gas, which generally causes a pp. of droplets containing some of the alkaloids, and adherent to the side of the vessel. The ethereal solution is poured off, mixed with about half its volume of water, and a current of carbon dioxide is again passed for twenty minutes, which may cause the ppn. of other alkaloids not ppd. by dry carbon dioxide. Usually the whole of the alkaloids are thrown down by these means, but if not, the ethereal solution is dehydrated by shaking with barium oxide, and then a solution of tartaric acid in ether is added to the clear liquid, taking care not to employ an excess of acid; any alkaloid that may remain in solution is thus thrown down. As a matter of precaution, the remains of the viscera or other matters operated on are mixed with barium hydrate and a little water, and agitated with pure amyl alcohol. The alkaloids may then be extracted from the alcohol by shaking it in a stoppered tube with very dilute sulphuric acid.

Sonnenschein (*A.* 104, 45) separates the alkaloids by ppn. with phosphomolybdic acid. In extracting the bases, the organic matter to be examined is repeatedly exhausted with very dilute hydrochloric acid, the mixed solutions filtered, and the filtrate evaporated in the oven at a temperature not exceeding 35° to a thin syrup; then diluted with water, cooled, and filtered. An excess of phospho-molybdic acid is added to the filtrate, and the pp. is washed with water containing nitric and phosphomolybdic acids. The still moist pp. is washed into a flask, made distinctly alkaline by the addition of barium hydrate, and distilled into a bulb apparatus charged with hydrochloric acid, which absorbs ammonia and the volatile bases. The residue in the flask, containing the non-volatile bases, is freed from barium hydrate by a current of carbon dioxide, evaporated to dryness, and the bases extracted by means of strong alcohol. The filtered alcoholic solution often yields on evaporation the alkaloids in a sufficient state of purity to admit of their being weighed, converted into hydrochlorides, and submitted to tests. Sometimes, however, they must be purified by re-solution and re-crystallisation from absolute alcohol, ether, chloroform, &c.

The method of Uslar and Erdmann (*A.* 120, 121) is not much employed in this country, the evaporation of amyl alcohol being a disagreeable operation; but it is nevertheless a valuable process for the separating of strychnine and morphine. It is practised as follows:—The suspected matter, if solid, is made into thin paste with water, slightly acidulated with hydrochloric acid, and digested at a temperature of 70° for an hour or two. It is then strained through a moist piece of cambric, and the solid residue on the cloth is well exhausted with hot very dilute hydrochloric acid. The combined liquids after filtration are made slightly alkaline with ammonia, mixed with clean sand, and evaporated to dryness on the water-bath. The residue from the evaporation is extracted three or four times with hot amyl alcohol and the mixed liquids are filtered. The filtrate is shaken violently in a stoppered tube with several times its volume of hot water acidulated with hydrochloric acid, which removes the alkaloids, leaving colouring matters and fat in the alcohol. The alcohol is pipetted off, and the hot acid solution is repeatedly washed by agitation with fresh portions of amyl alcohol until all fat and colouring matter is removed, after which the clear aqueous liquid is concentrated by evaporation, made alkaline with ammonia, and well shaken with fresh hot amyl alcohol four or five times. These alcoholic liquids are mixed, filtered through a filter moistened with amyl alcohol to remove water, and evaporated in a tared basin, when the alkaloids will be left in a sufficiently pure condition to be dissolved and tested, previous to which they should be weighed. Occasionally a coloured residue is obtained which requires re-solution in aqueous acid, agitation with amyl alcohol, alkalisation with ammonia, and re-extraction with amyl alcohol, in order to obtain the alkaloids in a sufficiently pure state for testing. With morphine the process, though tedious, works well.

Scheibler's process is based upon the precipitation of the alkaloids by phosphotungstic acid, a reagent prepared by treating sodium tungstate in solution with half its weight of phosphoric acid, when crystals of phosphotungstic acid slowly form. These are dissolved, and the process in detail is carried on in the same manner as Sonnenschein's phosphomolybdic acid process, substituting the phosphotungstic for the phosphomolybdic solution as a precipitant. It is sometimes recommended to precede the ppn. of the alkaloid by the addition of lead acetate to remove colouring matter, and then to remove the excess of lead by hydrogen sulphide; but some of the alkaloid present is apt to be removed with the lead pps. Nor should animal charcoal be used as a decolorant, as this is still more effective in withdrawing the alkaloids from solution. Indeed the obstinacy with which the alkaloids adhere to animal charcoal has been utilised by Graham, Hofmann, and Redwood as a means of separating strychnine from beer and other liquids (*C. J.* 5, 173).

The following scheme serves for the detection of the more commonly occurring poisonous alkaloids. The alkaloids are brought into acid aqueous solution, and this is shaken with ether:—

I. *The ether withdraws from the acid aqueous solution*, and leaves on evaporation:

1. *Colchicine.*—Its solution is yellow, and is turned to a violet colour by strong nitric acid. Its solution in HClAq, when made alkaline with caustic soda, develops an orange-red colour.

2. *Digitalin.*—When dissolved in conc. H_2SO_4 and a minute quantity of bromine water is added, a reddish-violet tint is produced, which, on the addition of water changes to a green.

3. *Picrotoxin.*—Reduces Fehling's solution.

The solution is made alkaline with sodium bicarbonate, and again shaken with ether.

II. *Ether removes from the alkaline solution*, and leaves on evaporation:

1. *Nicotine.*—Oily droplets, having a tobacco-like odour. Its aqueous solution is not ppd. by chlorine water, nor does it become coloured when warmed. Warmed with hydrochloric acid the alkaloid becomes violet, and then on the addition of nitric acid orange-coloured.

2. *Coniine.*—Oily droplets having a mouse-like odour. Its aqueous solution is ppd. by chlorine water, and becomes coloured when warmed. Dry hydrochloric acid gas turns the alkaloid at first red, and then to a violet colour.

3. *Lobeline.*—Oily droplets yielding no very definite chemical reactions.

4. *Brucine.*—Turned rosy-red by strong sulphuric acid not quite free from oxides of nitrogen. The alkaloid is reddened by strong nitric acid, and the red solution changes to a bluish violet on the addition of a solution of stannous chloride.

5. *Strychnine.*—No coloration on the addition of strong H_2SO_4. On the further addition of solid potassium dichromate, MnO_2, or PbO_2, a violet-blue coloration is immediately produced, passing gradually into a cherry-red, the colour only slowly disappearing.

6. *Narcotine.*—It become first yellow, then bluish-violet when warmed with strong sulphuric acid. Its solution in strong H_2SO_4 becomes red on the addition of a trace of nitric acid. Sulphomolybdic acid turns the alkaloid green.

7. *Veratrine.*—With strong sulphuric acid it becomes yellow, orange, and finally cherry-red. Its solution in cold concentrated hydrochloric acid is colourless, but gradually changes to a deep red when boiled.

8. *Jervine.*—The salts of this alkaloid, except the acetate and phosphate are only very sparingly soluble in water and acid solutions. Its solution in acetic acid is ppd. by nitric acid and by potassium nitrate.

9. *Atropine.*—An odour of hawthorn is developed when the alkaloid is warmed with strong sulphuric acid and potassium dichromate; and the solution becomes green from reduction of chromic acid. Evaporated to dryness with fuming nitric acid, and the residue touched with an alcoholic solution of potash, a fine purple colour is produced.

10. *Aconitine* can only be identified by its physiological properties. The chemical tests for pure aconitine are not characteristic.

11. *Gelsemine.*—With strong sulphuric acid and potassium dichromate, a reddish-purple or cherry-red colour is developed, quickly passing into bluish-green or blue.

12. *Physostigmine.*—Its solutions, whether acid or alkaline, become reddish on exposure, and this colour is discharged by sulphurous acid and the thiosulphates. Treated with sulphuric acid and bromine-water, it yields a brown-red colour.

III. *There remain in the alkaline aqueous solution*:—

Morphine, curarine, and cytisine. The first may be separated by shaking with acetic ether, and is identified by the usual tests—nitric acid, ferric chloride, iodic acid and starch, and sulphomolybdic acid. Curarine may be ppd. by phosphomolybdic acid after acidification with nitric acid. The pp. is decomposed by barium hydrate, and the alkaloid extracted by absolute alcohol (*v.* Sonnenschein's process, *ante*); it gives a reddish colour with sulphuric acid, and reacts somewhat like strychnine with sulphuric acid and potassium dichromate. Curarine, however, is not precipitated from its solutions by potassium dichromate.

Cytisine yields no definite chemical reactions.

The following are the chief trustworthy tests for the more commonly occurring poisonous alkaloids, &c.:—

Aconitine.—This alkaloid, as well as the closely allied alkaloids pseud-aconitine and japaconitine, when pure, yield no characteristic chemical reactions. The colour reactions with sulphuric and phosphoric acids that have been described by authors are untrustworthy, and due to impurities.

Apomorphine.—Its salts turn green on exposure to light and air, and its solutions on boiling. With sodium bicarbonate its solutions yield a pp. which turns green on standing, and forms with ether a purple, and with chloroform a violet, solution. Its solutions strike a red colour with ferric chloride and with nitric acid.

Atropine.—When warmed with strong sulphuric acid—or, more quickly, when evaporated to dryness with baryta-water, and the residue heated—an odour of stale hawthorn flowers is developed.

Brucine.—It is turned of a blood-red colour by nitric acid; and the red solution becomes violet on the cautious addition of a solution of stannous chloride. It yields an orange-red with sulphomolybdic acid; and with sulphuric acid and potassium dichromate a deep orange-red colour.

Caffeine.—Crystallises in silky needles. Evaporated to dryness with dilute hydrochloric acid and a fragment of potassium chlorate, a pink residue is left, which turns violet on the addition of ammonia.

Cinchonine.—It is difficult to get any characteristic reaction for this base. Its sulphate is soluble in chloroform, and is non-fluorescent—characters which distinguish it from quinine.

Cocaine.—Is not coloured by concentrated acids. When evaporated to dryness with alcoholic potash, the residue when warmed with dilute sulphuric acid evolves an aromatic odour of benzoic acid.

Colchicine.—Nitric acid strikes a violet colour, which on the addition of sodium hydrate changes to a fine orange. Strong sulphuric acid dissolves the alkaloid to a greenish yellow colour, and on the addition of a drop of dilute nitric acid a play of colours, beginning with violet, is manifested. The subsequent addition of caustic soda yields a fine rose tint.

Coniine.—Oily, and of a mouse-like odour. Its dilute aqueous solution fumes with strong hydrochloric acid, and after acidification gives no pp. with bromine-water until supersaturated with sodium hydrate, when a white pp. forms.

Curarine.—Is turned blue violet when touched with sulphuric acid and potassium dichromate added; but the colour is more persistent than in the case of strychnine.

Cytisine.—This alkaloid is insoluble in ether, benzene, chloroform, and carbon disulphide. It dissolves in sulphuric acid without colour, but the subsequent addition of nitric acid produces an orange coloration. Nitric acid dissolves cytisine without colour, but on warming the mixture becomes orange-red.

Emetine is said to strike a blood-red colour with strong nitric acid, but the writer believes that this is due to impurities, and that tests for emetine are desiderata.

Gelsemine.—Sulphuric acid and potassium dichromate produce an immediate but evanescent violet coloration, and the chromate is quickly reduced. The alkaloid is naturally associated with gelsemic acid, a substance which in alkaline solution fluoresces strongly, and is yellow by transmitted, blue by reflected light.

Hyoscyamine.—No good chemical test for this alkaloid is known.

Jervine.—The salts of this alkaloid, especially the acetate, are ppd. by nitric acid and by potassium nitrate.

Morphine gives with nitric acid a deep red colour, not materially altered by the subsequent addition of stannous chloride. With sulphuric acid and potassium dichromate a green coloration is gradually developed. Ferric chloride gives a blue or blue-green coloration. It liberates iodine from iodic acid, and the mixture shaken with chloroform imparts a violet tint to this; but the brown colour is only deepened and altered in tint by ammonia. Sulphomolybdic acid gives an immediate purple coloration.

Narcotine.—Uncoloured by sulphuric acid, except this contains a trace of nitric acid, when a fine cherry-red colour is gradually developed, and is persistent. Its acidulated solution when warmed with bromine-water, added drop by drop, develops a purple or violet tint.

Nicotine.—Oily, and having the odour of tobacco. Freely soluble in water. Its acidulated solutions give a copious pp. with bromine-water, and this pp. disappears when excess of sodium hydrate is added.

Physostigmine.—Sulphuric acid gradually produces a reddish colour. Its solutions acquire a red colour on standing, and at once when treated with sodium hydrate and warmed, and on evaporation leave a bluish residue which on acidulation affords a dichroic (red and blue) solution, which becomes permanently red on standing.

Pilocarpine affords no very characteristic chemical reactions. With sulphuric acid and potassium dichromate a green colour, due to reduction, is developed.

Piperine has the pungent fragrant odour of pepper. It is turned of a deep red colour by sulphuric, and of an orange colour by nitric acid.

Quinine.—Its solution in sulphuric acid is fluorescent. Treated with bromine-water and then excess of ammonia added, an emerald green coloration is produced.

Salicin.—A neutral glucoside. It is not withdrawn from its acid or alkaline solutions by ether, benzene, or chloroform, and hence is not obtained in the ordinary processes for the separation of the alkaloids. It is turned of a cherry-red colour by sulphuric acid, and then on the addition of potassium dichromate an odour of meadow-sweet is evolved. Fused and partially sublimed in a test-tube, and then dissolved in water, ferric chloride strikes a violet colour.

Strychnine.—Sulphuric acid gives no colour till potassium dichromate, MnO_2, PbO_2, or ferricyanide of potassium is added, when immediately a fine blue-violet colour is produced which gradually passes into reddish-violet, red, and finally cherry-red. Evaporated to dryness with fuming nitric acid, and the residue moistened with alcoholic potash a deep orange colour is produced.

Veratrine.—Touched with strong sulphuric acid, this alkaloid gradually develops a fine red colour, or immediately on warming. Its solution in cold strong hydrochloric acid is colourless, but becomes intensely red on boiling.

T. S.

ALKAMINES, alcamines, alkines, or alcines. Names used by Ladenburg to denote substances that contain both alcoholic hydroxyl and amidogen, such as oxy-ethyl-amine, $C_2H_4(OH).NH_2$.

ALKANET. The commercial name of two different plants. True alkanet is *Lawsonia inermis*, false alkanet is *Anchusa tinctoria*. The leaves of *Lawsonia* contain a yellow dye, its roots contain a red pigment, used as a cosmetic. The root of *Anchusa* (*Orcannette*, *Radix Alcannæ spuriæ*) contains anchusin.

Anchusin or Alkannin $C_{35}H_{40}O_8$ (Bolley a. Wydler, *A.* 62, 141) or $C_{17}H_{20}O_4$ (Pelletier, *A.* 6, 27) or $C_{15}H_{14}O_4$ (Carnelutti a. Nasini, *G.* 1880, 283; *B.* 13, 1514). Obtained by extracting the root of *Anchusa tinctoria* with petroleum; the crude product is treated with dilute potash, the filtrate is shaken with ether, and the alkannin is ppd. by a current of CO_2. It is a brownish-red mass with a metallic lustre; sol. ether, chloroform, and acetic acid, sl. sol. alcohol. Softens below 100°. Alcoholic solutions give with baryta-water a blue pp. of a barium compound. NaOAc and Ac_2O produce a crystalline diacetyl derivative: $C_{15}H_{12}Ac_2O_4$(?). Nitric acid forms oxalic and succinic acids. Alkannin appears to be allied to santalin. An alcoholic solution of alkannin dyes cotton mordanted with alum, violet; iron mordants give a grey colour. Turned blue by alkalis, especially ammonia (Böttger, *J. pr.* 107, 46; Enz, *J.* 1870, 935). Alkannin, unlike rosaniline, is not abstracted by cubes of gelatin from its solution. Its absorption-spectrum shows 3 bands, dividing the spectrum between D and the blue strontium line into 4 equal parts. On adding ammonia the red solution turns blue, now showing 2 bands, one at D, the other in the red, two-thirds of the way towards the lithium line (A. Dupré, *C. J.* 37, 572).

ALKARSIN. Name given by Bunsen to cacodyl or arsenic dimethide (*q. v.*), C_2H_6As, as being empirically alcohol in which O has been displaced by As (*A.* 24, 271).

ALKYL. An alcohol radicle.

ALKOYL. An acid radicle.

ALLANIC ACID $C_4H_5N_5O_5Aq$.

Formed, together with urea and allanturic acid by the action of nitric acid in the cold on allantoïn (E. Mulder, *A.* 159, 353). Stellate needles (from water). Sl. sol. cold water. Decomposes at 210°-220° without melting. Does not give off gas with HNO_3 containing N_2O_4. Gives no pp. with $CaCl_2Aq$ and NH_3Aq. Gives pps. with $AgNO_3Aq$ and NH_3Aq, and with basic lead acetate, but not with neutral lead acetate.

Salts.—NH_4A': prisms.—$HO.Pb.A'$: ppd. by basic lead acetate.—$2PbA'_2 5Pb(OH)_2$—AgA' aq: amorphous pp.

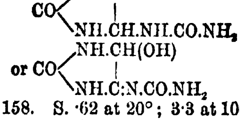
ALLANTOÏC ACID

$C_4H_8N_4O_4$ *i.e.* $NH_2.CO.NH.CH(CO_2H).NH.CO.NH_2$

A solution of allantoïn in aqueous potash which has stood for some days, no longer gives a pp. with acetic acid, even after some time; but if a little alcohol be also added, and the liquid be left in an exsiccator over lime, crystalline potassic allantoate, KA′, separates (E. Mulder, *A.* 159, 362; Schlieper, *A.* 67, 231; Ponomarew, *J. R.* 11, 13). The solution of potassic allantoate gives crystalline pps. with $Pb(OAc)_2$ and $AgNO_3$, but not with $BaCl_2$. $BaCl_2$ and alcohol give a hygroscopic curdy pp.

Salts.—NH_4A'—NaA' aq.—KA'.—BaA'_2 2aq.—PbA'_2 aq.—AgA'.

ALLANTOÏN $C_4H_6N_4O_3$ *i.e.*



$$CO\left\langle\begin{array}{l}NH.CO\\ \quad\;|\\ NH.CH.NH.CO.NH_2\end{array}\right. \quad \text{or } CO\left\langle\begin{array}{l}NH.CH(OH)\\ \quad\;|\\ NH.C{:}N.CO.NH_2\end{array}\right.$$

Mol. w. 158. S. ·62 at 20°; 3·3 at 100°.

Occurrence.—In the allantoïc liquid of the cow (Lassaigne, *A. Ch.* [2] 17, 301; compare Vauquelin, *A. Ch.* 33, 269). In urine of sucking calves (Wöhler, *A.* 70, 229). Occasionally in urine of dogs (Salkowski, *B.* 9, 721; 11, 500; Meissner a. Jolly, *Z.* 1865, 131). In the young leaf-buds of the plane and maple, and in the bark of the horse-chestnut tree (E. Schulze, *B.* 14, 1602; *J. pr.* 133, 147; *H.* 9, 425). In wheat, to the amount of ·5 p.c. of the embryo (Richardson a. Crampton, *B.* 19, 1181).

Formation.—1. By treating uric acid with boiling water and PbO_2 (Liebig a. Wöhler, *A.* 26, 244; E. Mulder, *A.* 159, 349), with KOH and potassic ferricyanide (Schlieper, *A.* 67, 216), or with $KMnO_4$ (Claus, *B.* 7, 227).—2. By heating glyoxylic acid (1 pt.) with urea (2 pts.) eight hours at 100° (Grimaux, *C. R.* 83, 62).—3. By the action of nitrous acid on dialuric acid (Gibbs, *A. Suppl.* 7, 337).—4. By heating mesoxalic acid with urea at 110° (Michael, *Am.* 5, 198).

Properties.—Glassy monoclinic prisms (Dauber, *A.* 71, 68). Tasteless. Neutral. Readily soluble in alcohol.

Reactions.—1. Dry *distillation* gives ammonic carbonate and cyanide, and charcoal.—2. Gently heated with *hydrochloric* or *nitric acid* it gives urea and allanturic acid.—3. Hot *sulphuric acid* forms CO_2, CO, and NH_3.—4. Boiled with *baryta-water*, CO_2, NH_3, oxalic acid, and hydantoïn are got (Baeyer, *A.* 130, 161).—5. Hot conc. *potash* forms CO_2, NH_3, oxalic acid, and acetic acid.—6. Cold *potash* slowly forms allantoïc acid (*q. v.*).—7. *Nitric acid* of S.G. 1·35 forms, on boiling, allanic acid (*q. v.*).—8. *Potassic ferricyanide* and KOH form allantoxanic acid (Mulder, *B.* 8, 1291).—9. *Sodium amalgam* forms glycoluril, $C_4H_6N_4O_2$ (Strecker a. Rheineck, *A.* 131, 119).—10. *Hydric iodide* reduces it to urea, and hydantoïn or glycolyl-urea (Baeyer, *A.* 117, 178).

Tests.—1. A conc. solution of furfurol, to which a little HCl has been added, gives a violet colour with an aqueous solution of allantoïn (Schiff, *B.* 10, 771).—2. Mercuric nitrate (but not chloride) gives a pp., as with urea. 100 g. of dry allantoïn require 172 g. of mercuric oxide. The pp. is $(C_4H_6N_4O_3)_4 5HgO$.

Compounds with Bases.—These are formed by boiling aqueous solutions of allantoïn with metallic oxides. They are sparingly soluble (Limpricht, *A.* 88, 94).—

$(C_4H_6N_4O_3)_2CdO$.—$C_4H_6N_4O_3ZnO$.—
$(C_4H_6N_4O_3)_6 5HgO$.—$(C_4H_6N_4O_3)_3 2HgO$.—
$(C_4H_6N_4O_3)_4 3PbO$.—$(C_4H_6N_4O_3)_6CuO$.

The following are described as true salts: $AgC_4H_5N_4O_3$, got as a pp. by ammoniacal $AgNO_3$.—$KC_4H_5N_4O_3$: from allantoïn, KOHAq, and alcohol, in exsiccator.

Nitrate $C_4H_6N_4O_3HNO_3$. Amorphous. Decomposed by water or alcohol into HNO_3 and allantoïn.

Constitution.—The constitutional formulæ given above are chiefly based upon *Formation* 2 and *Reaction* 10.

ALLANTOXAÏDIN

$C_3H_3N_3O_2$ aq *i.e.*

$$CO\left\langle\begin{array}{l}NH.CO\\ \quad\;|\\ NH.C{:}NH\end{array}\right. \text{aq.}$$

When allantoxanic acid is liberated from its salts, it at once splits up into CO_2 and this body (Ponomarew, *J. R.* 11, 47). Glittering prisms or tables. V. sol. boiling water, sl. sol. cold water or alcohol, insol. ether. Decomposed by heat, giving off HCN, HCNO, and NH_3. Acid reaction. Boiled with water, or treated with cold Na_2CO_3Aq, it splits up into formic acid and biuret.

Salts.—KA': ppd. by alcohol.—AgA'.

ALLANTOXANIC ACID $C_4H_3N_3O_4$ *i.e.*

$$CO\left\langle\begin{array}{l}NH.CO\\ \quad\;|\\ NH.C{:}N.CO_2H\end{array}\right.$$

Formation.—1. Allantoïn dissolved in aqueous KOH is treated with potassic ferricyanide until the colour is permanent. Acetic acid is then added, when $C_4H_2KN_3O_4$ is ppd. (Van Embden, *A.* 167, 39).—2. From allantoïn, KOH, and $KMnO_4$ (Mulder, *B.* 8, 1292; Ponomarew, *J. R.* 11, 19).—3. From oxalyl-di-ureïde and aqueous potash (P. *B.* 18, 982).

Properties.—The acid, liberated from its lead salt by H_2S, splits up into allantoxaïdin and CO_2.

Salts.—NH_4A': needles.—$(NH_4)_2C_4HN_3O_4$.

—KA′: silky needles. S. ·86. Boiled with water, it gives CO_2, biuret, and formic acid. Reduced by sodium-amalgam to hydroxonic acid.—$K_2C_4HN_3O_4$ aq: v. sol. water, insoluble in dry alcohol.—$Ba(C_4H_2N_3O_4)_2$ 6aq. — $BaC_4HN_3O_4$ 2aq. —$Pb(C_4H_2N_3O_4)_2$ 1½aq: very thin needles.—$PbC_4HN_3O_4$. — $AgC_4H_2N_3O_4$: crystalline pp. — $Ag_2C_4HN_3O_4$: gelatinous.

Ethyl ether $C_4H_2EtN_3O_4$: from AgA′ and EtI.

ALLANTURIC ACID $C_3H_4N_2O_3$ *i.e.*

Glyoxyl-urea.

Formation.—1. By boiling allantoïn with HNO_3, HCl or PbO_2 or heating with water at 140° (Pelouze, *A. Ch.* [3] 6, 71; Mulder, *A.* 159, 359).—2. Formed, together with glycoluril and urea, by action of sodium-amalgam on allantoïn (Reinecke, *A.* 134, 220).—3. By boiling allantoïc acid or alloxanic acid with water (Ponomarew, *J. R.* 11, 15; Schlieper, *A.* 56, 5).—4. By oxidation of hydantoïn (Baeyer, *A.* 117, 179; 130, 160).—5. By boiling uroxanic acid with water (Medicus, *B.* 9, 1162; Ponomarew, *B.* 11, 2155).

Properties.—A deliquescent gummy mass. Insol. alcohol. Boiling potash forms CO_2, NH_3, acetic acid, and oxalic acid (Medicus, *B.* 10, 544). —Salts. These are amorphous.— KA′HA′ 2aq. S. 10.—BaA'_2 3aq.

ALLENE. Name sometimes used instead of Allylene.

ALLITURIC ACID $C_6H_8N_4O_4$.
S. 5 or 6 at 100°. Obtained from an aqueous solution of alloxantin, mixed with HCl, by rapidly evaporating to a small bulk, and treating the resulting powder with HNO_3 which dissolves alloxantin but not allituric acid. The latter crystallises from water as a bulky yellowish-white powder (Schlieper, *A.* 56, 20). Not attacked by conc. H_2SO_4 or HNO_3. Evolves NH_3 when boiled with KOH.

ALLO.—A prefix proposed by Michael (*B.* 19, 1378) to denote unexplained isomerism; thus fumaric acid would be called allo-maleic acid.

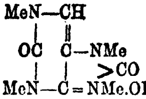
ALLOCAFFEÏNE $C_8H_9N_3O_5$.
[196°]. (E. Fischer, *A.* 215, 276).

Formation.—1. Obtained by action of water on the unstable product of addition of bromine to caffeïne methylo-hydroxide.—2. One of the products of action of HCl and $KClO_3$ on caffeïne methylo-hydroxide (Schmidt a. Schilling, *A.* 228, 162).

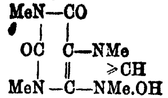
Small white trimetric crystals, $a:b:c=$ ·6953:1:·5401, soluble in benzene, chloroform, and hot water, nearly insoluble in cold water, sparingly in alcohol or ether.

Reactions.—1. Decomposed by *boiling water* into CO_2 and methyl-caffuric acid. Allocaffeïne is therefore probably methyl-apocaffeïne.—2. HNO_3 (S.G. 1·2) gives cholestrophane, methylamine, and CO_2.—3. HCl and $KClO_3$ form di-methyl-alloxan, amalic acid, cholestrophane, methylamine, and CO_2.—4. *Bromine* appears to form an addition product, but it is decomposed by water into allocaffeïne, cholestrophane, and methylamine hydrobromide.—5. Boiling baryta forms sarcosine, formic acid, and CO_2.

Constitution.—Inasmuch as it splits off $NMeH_2$ in reactions where caffeïne splits off NH_3, the Me (and consequently OH also) must be attached to nitrogen, the formula being either:



or



(after Fischer) (after L. Medicus).

ALLOPHANIC ACID $C_2H_4N_2O_3$
i.e. $NH_2.CO.NH.CO_2H$ *Urea ν-carboxylic acid.* The free acid splits up at once into CO_2 and urea. Its ethers are formed by passing vapour of cyanic acid into alcohols: $2CONH + HOEt = NH_2.CO_2Et + CONH = NH_2.CO.NH.CO_2Et$. The ethers are sparingly soluble crystalline solids.

Salts.—BaA'_2: obtained from the ether by cold baryta-water (Liebig a. Wöhler, *A.* 59, 291). When boiled with water it gives off CO_2, deposits $BaCO_3$, and urea is left in solution. Dry distillation produces basic cyanate, NH_3, and CO_2. It gives no pp. with $AgNO_3$.—Salts of Ca, K, and Na have been prepared.

Methyl allophanate $NH_2.CO.NH.CO_2Me$ (Richardson, *A.* 23, 138).

Ethyl allophanate EtA′. [191°]. 1. From alcohol and the vapour of cyanic acid (L. a. W.). 2. From $ClCO_2Et$ and urea (Wilm a. Wischin, *Z.* [2] 4, 5).—3. Together with oxamide and alcohol by heating urea with oxalic ether at 135°-170° (Grabowski, *A.* 134, 115).—4. From potassic cyanate, alcohol, and chloro-acetic ether (Saytzeff, *A.* 135, 230) or chloroformic ether, $ClCO_2Et$ (Wilm, *A.* 192, 244).—5. From potassic cyanate, alcohol, and HCl (Amato, *G.* 3, 469). Small needles. Tasteless. Sl. sol. cold water, more soluble in alcohol. V. sl. sol. cold ether (difference from carbamic ether). At 190° it slowly changes to alcohol and cyanuric acid. Alcohol at 160° converts it into carbamic ether: $NH_2.CO.NH.CO_2Et + HOEt = 2NH_2CO_2Et$ (Hofmann, *B.* 4, 268).

Acetyl derivative, $NHAc.CO.NH.CO_2Et$. [107°]. Silky needles (from alcohol) (Seidel, *J. pr.* [2] 32, 273).

Benzoyl derivative $NHBz.CO.NH.CO_2Et$. [163°]. Together with alcohol, HCl, and CO_2 from benzoyl chloride and urethane (Kretschmar, *B.* 8, 104).

Propyl allophanate PrA′. [150°-160°]. (Cahours, *J.* 1874, 834).

Amyl allophanate $C_5H_{11}A'$. [162°]. From cyanic acid and amyl alcohol (Schlieper, *A.* 59, 23). From amyl alcohol and urea (Hofmann, *B.* 4, 267). Unctuous pearly scales (from water).

Oxethyl allophanate $HO.C_2H_4A'$. [160°]. From glycol and cyanic acid vapour. Shining laminæ (from alcohol) (Baeyer, *A.* 114, 160).

Di-oxy-propyl allophanate $C_3H_5(OH)_2A'$. [160°]. From glycerin and cyanic acid vapour (B.). Plates (from alcohol). Sol. water. Heated with baryta-water, it forms $BaCO_3$, urea, and glycerin.

Phenyl-allophanate PhA′. Cyanic acid vapour is passed into phenol; the product is dissolved in alcohol and ppd. by ether. Slender crystals. At 150° it splits up into cyanic acid and phenol (Tuttle, *J.* 1857, 451).

Propenyl-methoxy-phenyl-allophanate $C_{12}H_{14}N_2O_4$ *i.e.*
$NH_2.CO.NH.CO.O.C_6H_3(C_3H_5).OCH_3$.
From eugenol and cyanic acid vapour (Baeyer.

A. 114, 164). Needles. Insol. water. Sl. sol. cold alcohol.

Amide of allophanic acid $NH_2.CO.NH.CO.NH_2$ v. Biuret.

ALLOTROPY (otherwise turned, otherwise formed, from *ἄλλος* = another, and *τρόπος* = manner) denotes the appearance of one and the same substance in several different states, distinguished from each other by different properties. The term was introduced by Berzelius in 1840 (*J.* No. 20 for 1839, pt. ii. p. 13), because he held the term 'isomerism' to be inadmissible where the subject of modification is an *elementary* substance, isomeric states being traceable to different modes of combining equal numbers of atoms of the same elements. In the view of Berzelius, accordingly, the allotropic modifications of *the elements* are not to be explained by differences in the arrangement of their atoms, but he expressed no opinion whatever about their actual cause. Since, however, he indicated it as probable that even in compounds the elements retain their allotropic states, and thereby often occasion isomeric forms of compounds (*J.* No. 23, p. 51; No. 24, p. 32), he appears to have been of opinion that the cause of the allotropic transformation is to be sought in a change in the atoms themselves. Now that we have learned to appreciate more correctly the doctrine of Avogadro, and so have become accustomed to consider the molecules of the majority of elements as particles composed, like those of compounds, of several atoms, the distinction introduced by Berzelius between allotropy and isomerism has lost its original meaning. But the term allotropy has been retained, being used, however, with reference not to elements only but also to compounds. Accordingly we distinguish between *allotropy of elements* and *allotropy of compounds*. The former, according to the modern use of the expression, embraces all the different forms in which an element appears; the latter only those cases in which, while the composition remains the same, there is a change in the physical, but none, or at any rate none of any consequence, in the chemical, properties, thus apparently warranting the assumption that there has been no change in the linkage of the atoms by which, doubtless, chemical behaviour is essentially determined. Allotropy of compounds is accordingly synonymous with physical, as opposed to chemical, isomerism. But since the two groups of properties are closely connected, and any change of the physical is usually accompanied by a change, however small, of the chemical also, no sharp line is to be drawn between the two kinds of isomerism.

On the other hand, the transformation of one allotropic form into another offers so many analogies to the transformation of one state of aggregation into another that, strictly speaking the three states of aggregation of any substance should be described as three allotropic modifications of it (Lehmann, *Z.K.* 1877. 1, 97). Hitherto, however, it has not been usual so to describe the states of aggregation, and, consequently, on this side also, the notion of allotropy is not to be defined with perfect exactness. The melting of ice, for example, is a transformation of the lighter into the heavier modification of water, for the particles of the lighter are still retained in the liquid state for some degrees above the melting point, and bring it about that the maximum of density appears not at 0° but at +4°. Something similar probably takes place in many, if not in all, other substances, only the difficulties of observation are greater. But as it has been observed that changes in the properties of a substance usually proceed differently and follow different laws according as the substance is near to, or more remote from, its melting-point (no matter whether above or below it), we may conclude that immediately below the melting point the solid substance already contains isolated portions of the liquid modification, and that above the melting point the liquid body still contains portions of the solid modification. But even if we do not account these changes of aggregation as instances of allotropy, the number of cases of allotropy as yet known, while suffering a very important diminution, will still remain pretty considerable.

I. Allotropy of the Elements.—Allotropy, taken in the narrower sense, has hitherto been observed only in the non-metallic or semi-metallic elements. Among metals proper it has been found only as regards crystalline form, in which case it is usually known as *dimorphism* or *polymorphism*. Since, to the best of our present knowledge, the gaseous molecules of the metals consist of single atoms,[1] while those of the semi-metals and non-metals are composed of several atoms, the absence of allotropic modifications of the metals proper tells in favour of the present view, which is different from that of Berzelius, and is to the effect that allotropy of the elements, like isomerism of compounds, depends on differences in the mode of union of the atoms, and not on any changes in the atoms themselves. Polymorphism, occurring as it does even among metals, may be explained by supposing that there are differences in the arrangements of the atoms as well as of the molecules, while the existence of allotropic modifications in the melted, the dissolved, or the gasified, state points to differences in the constitution of the molecules, *i.e.* to different modes of uniting the atoms to form molecules.

The appearance of allotropy seems to be favoured by smallness of atomic weight, for not unfrequently in one and the same natural family allotropy shows itself only in the first members, while the members with higher atomic weights exhibit it either in some properties only or not at all. In the **family of the halogens**, F, Cl, Br, I, allotropy has not been observed, unless we consider as such the splitting of molecules at high temperatures into separate atoms (Victor Meyer). **Hydrogen** does not exhibit allotropy. On the other hand allotropy is found very notably in the first members of the **oxygen-sulphur family**. *Ozone* exhibits much more strongly marked chemical characters, and moreover a greater density, than oxygen. If the molecular weight of ordinary oxygen is represented by O_2, that of ozone is probably O_3, ozone being thus a polymeride of oxygen. *Sulphur* in each of its states of aggregation exhibits allotropic modifications, and these to some extent correspond with each other. In the solid state it is: (1) rhombic;

---

[1] It should not be forgotten that the data are most meagre.—Ed.

D. = 2·07, melting-point 113° (Gernez), soluble in CS_2: (2) monoclinic; D. = 1·96, M.P. 117° (Gernez), soluble in CS_2: (3) amorphous plastic; D. = 1·90 to 1·93, insoluble in CS_2: (4) according to Gernez (*C. R.* 98, 144) and Sabatier (*C. R.* 100, 1346) crystallised in little rods with a lustre like that of mother-of-pearl. The last modification Maquenne (*C. R.* 100, 1499) considers to be distorted rhombic crystals, which according to Gernez are very easily produced out of the fourth modification (*C. R.* 100, 1584) without being identical with it. Liquid sulphur is: (1) immediately above the melting-point thin and clear: (2) at about 200° thick and dark: (3) at about 340° thin and dark. The vapour: (1) between the boiling-point (446°) and about 500° has V.D. = 6·6, molecular weight = S_6: (2) above 700° V.D. = 2·2, molecular weight = S_2. The behaviour of *selenion* is analogous to that of sulphur. When solid this substance is: (1) red, amorphous, vitreous, or pulverulent, D. = 4·26, soluble in CS_2: (2) red, crystallised, monoclinic, isomorphous with sulphur, D. = 4·51, soluble in CS_2: (3) gray, granularly crystalline, D. = 4·80, insoluble in CS_2. Whether the black foliated crystals, insoluble in CS_2, D. = 4·80, obtained from a solution of potassium selenide, are identical with the third modification remains to be determined. Liquid selenion is: (1) at low temperatures in a thin stratum light-red and transparent: (2) at higher temperatures, dark. Gaseous selenion under 1400° consists in part of molecules composed of more than two atoms: above 1400° all the molecules are diatomic, V.D. = 5·68, molecular weight Se_2. Of *tellurium* no allotropic form is known with certainty, yet it is worthy of remark that its electrical conductivity, like that of selenion, but contrary to that of all other conductors of the first class, increases with rising temperature. This may be explained by supposing the production of a modification with better conductivity. As regards the nitrogen family, the existence of any allotropic forms of *nitrogen* has not yet been conclusively proved, but solid *phosphorus* exists in three forms: (1) colourless, very easily burnt, soluble in CS_2 and in many oils, crystallising out of these solutions according to the regular system, D. = 1·83: (2) red, amorphous, D. = 2·18: (3) dark-red crystallised in rhombohedral forms, in the highest degree indifferent, D. = 2·34. The last two forms perhaps represent one and the same modification. In the liquid state there seems to be only one modification—the colourless; in the gaseous state, on the contrary, there appear to be two, since the vapour-pressure over colourless phosphorus is greater than that over red at the same temperature, and the vapour condenses under certain circumstances into the one modification and under other circumstances into the other. *Arsenic* is: (1) amorphous, D. = 4·72, less easily oxidised than the following variety: (2) crystallised in rhombohedral forms, D. = 5·73. Whether explosive *antimony* (Gore), D. = 5·83, is a distinct modification cannot be quite definitely determined, since it cannot be obtained free from chloride. For ordinary antimony D. = 6·71. Of *bismuth* no allotropic modification is known.

In the carbon family *carbon* exists: (1) as diamond, regular, very hard, D. = 3·52: (2) as graphite, either rhombohedral (Kenngott), or monoclinic (Clarke, Nordenskiöld), D. = 2·32: (3) amorphous charcoal, D. = 1·87 to 2·30, agreeing with graphite in many properties and hence perhaps not to be regarded as a distinct modification. *Silicon*: (1) amorphous, easily oxidised: (2) crystallised according to the regular system, D. = 2·20 to 2·49. The so-called graphitoidal variety consists of distorted regular crystals. Of *titanium* and *thorium* allotropic forms are not known. *Zirconium* has been obtained amorphous and crystallised. *Tin* also appears to be dimorphous.

The element boron is probably capable of allotropic modification, yet hitherto it has been obtained *pure* only in the amorphous form. The crystallised always contains aluminium or carbon. Some of the platinum metals, namely *iridium* and *palladium* are said to occur in two forms, regular and hexagonal.

II. ALLOTROPY OF COMPOUNDS, OR PHYSICAL ISOMERISM, may be theoretically defined as *isomerism with identity of atomic linkage*. The following inorganic compounds exhibit remarkable instances of allotropy: *calcium carbonate* (as calc-spar and arragonite); *silica* (quartz, tridymite, agate); *titanium oxide* (rutile, brookite, anatase); the *nitrates of sodium, potassium, ammonium*, and *silver*; *sodium metaphosphate*; *arsenious* and *antimonious oxides*; the *sulphates* of *magnesium, iron*, and *copper*; *potassium dichromate*; *silver iodide*; *zinc chloride*; *mercuric chloride*; *manganous chloride*; and indeed many other substances. Many instances of allotropy have also been observed among the compounds of carbon, particularly in the following substances: *benzophenone*; *isohydrobenzoin diacetate* (Zincke); *dibromopropionic acid* (Tollens); *tolylphenyl ketone* (Van Dorp, Zincke); *metachloronitrobenzene*; *chlorodinitrobenzene* (1:3:4) (Laubenheimer); *oxycamphoronic acid* (Zepharowich); the benzoylated and anisylated *hydroxylamines* (Lossen); *hydroquinone*; *paranitrophenol*; *stilbene chloride*; *dibromofluorene* (Lehmann); *tetramethyldiamido-triphenyl-methane*; *diphenylnaphthylmethane*; *pentamethylleukaniline* (E. Fischer, Lehmann); *dibenzoyl-diamidodibromodiphenyl* (E. Lellmann). No definite and regular relation between the composition of carbon compounds and the existence of allotropic forms of these compounds has as yet been recognised.

The production of allotropic modifications, and the transformation of one modification into another, are effected, as a general rule, by changes of temperature. The cases in which we are entirely ignorant of the conditions under which allotropic modifications are produced, are but few. The most notable is that of one of the modifications of carbon—the diamond, but on the other hand the transformation of diamond into graphite has been observed. One of the allotropic states usually corresponds to a specified interval of temperature, so that at a definite limit of temperature the one modification passes into the other. Yet we frequently succeed in cooling the modification belonging to the higher temperature below the lower limit, and sometimes also in heating the other modification above this limit, without any transformation taking place. But when such a modification is preserved above its fixed limit, the state of equilibrium attained by its particles is unstable, and is often destroyed by very trifling causes, a particularly easy means of upsetting it being to bring the substance into contact with a crystal of the modification that is stable at the prevailing temperature. On transformation into the stable form thereupon ensuing, heat is produced or disappears, according as contraction or expansion takes place. This thermal effect may be very considerable.

The temperature of transformation has been determined for rhombic and monoclinic sulphur by L. Th. Reicher (*Z. K.* 1884. 8, 6) to be 95·6°. Below this the rhombic form is stable, above it the monoclinic, the other being unstable. The amorphous form is unstable at all temperatures below, and also for a considerable interval above, the melting point; the temperature at which it becomes stable has not been determined, but probably it lies not far below the boiling point. When cooled quickly both the monoclinic and the amorphous form may be kept a considerable time at comparatively low temperatures. One might be tempted to suppose that the modifications that have thus become unstable would pass into the stable forms the more easily the greater the distance of their temperature from that of transformation; yet below the temperature of transformation this is not the case; on the contrary, transformation into the rhombic modification ensues the more easily the higher the temperature and therefore the nearer it comes to the temperature of transformation. This is undoubtedly due to the circumstance that the mobility of the particles increases as the temperature increases. The behaviour of selenion is similar to that of sulphur. Amorphous selenion is produced only above the melting point, which is 217°, nevertheless when this variety is quickly cooled it remains stable for some time, and begins to pass into the grey crystalline form only at 80° (Hittorf); the progress of this change is however more rapid at 125°. The temperature of transformation of the red soluble crystals of selenion is about 110° (Mitscherlich).

The conditions under which phosphorus passes from one of its modifications into another are very remarkable. If colourless phosphorus is vaporised in a vessel too small to contain the whole of the phosphorus as vapour, the red variety is formed at 210° and upwards; the change proceeds more rapidly at 260°, and very quickly above 300°. Conversely, red phosphorus, if it can transform itself freely into vapour, and if the vapour is allowed to cool, is re-converted at 260° into the colourless form: the red modification is formed only if the vapour has been heated above a red heat and then allowed to cool (Hittorf). Arsenic vapour condenses below 220° to form amorphous arsenic; at a higher temperature to form crystallised. At 360° the former passes into the latter with production of heat. Tin is converted by very great cold, under conditions not yet exactly determined, into loosely cohering columnar aggregations of grey colour and diminished density (Fritsche, Petri, Schertel). Light too may bring about the production of allotropic modifications; through its influence selenion and tellurium temporarily acquire a better electric conductivity—a fact which has been applied in telegraphy. Phosphorus becomes red through the action of light. Electricity likewise may convert phosphorus, *in vacuo*, into the red modification, but perhaps the transformation may be due only to the heat produced.

Among compound substances the phenomenon of the transformation of one allotropic modification into another has been observed by many authors, but it has been studied with special attention by O. Lehmann (*passim*, and in later papers in *Z. K.*) He has proved that it obeys the same laws that hold for the elements. In most cases an unstable modification, differing from the ordinary stable one, is obtained by raising a substance to a high temperature and then cooling it quickly to a temperature a long way below that of transformation. It is supposed that in such circumstances the particles do not find time and opportunity to assume the position of equilibrium corresponding to the lower temperature. The unstable state thus produced may be assumed alike by solid, melted, and dissolved, substances, and may be maintained, especially at pretty low temperatures, for a long time. In many cases, *e.g.*, in that of hydroquinone, the one modification (in this case the unstable) is obtained by melting or subliming; the other form is obtained from solutions. In other cases, either form may be obtained from the same melted body, or from the same solution, according as it is brought into contact with a crystal of the one form or of the other. If fragments of crystals of both modifications are introduced simultaneously, both of them at first increase in size; but as soon as the two crystalline masses come into contact the form that is stable at the prevailing temperature grows into, and at the expense of, the unstable, while the latter dissolves or is consumed. As a general rule the modification that is unstable at a low temperature has a lower melting point than the stable, so that many substances on being heated are observed first to melt, then to solidify again, with transformation into the other modification, and finally to melt a second time. This phenomenon may be observed with special distinctness in the case of dibenzoyldiamidodibromodiphenyl, because here the melting points of the two forms lie unusually far apart. The needles of this substance crystallised out of alcohol melt at 195°, when quickly cooled the melted substance solidifies to a vitreous mass, which, when again heated, melts at 99°, re-solidifies in a crystalline form between 125° and 130°, and then melts once more at 195° (Lellmann).

Many compounds, especially inorganic compounds, behave like selenion; the form produced at high temperatures may remain stable far below the temperature of transformation, and may become unstable only on being heated to the neighbourhood of the temperature of transformation. Arragonite, the rhombic form of calcium carbonate, which separates from hot solutions (and according to G. Rose from very dilute cold solutions also) is perfectly stable at ordinary temperatures. If, however, a crystal is heated, it breaks up, long before giving off carbon dioxide, into a mass of small crystals of calc-spar (Haidinger), thus passing over into the rhombohedral form, which is produced at lower temperatures. Rock-crystal and amorphous silica are perfectly stable at ordinary temperatures, but at the temperatures of the porcelain-kiln they are changed into tridymite, the third modification, which in turn is likewise stable at lower temperatures. As regards other substances, particularly organic compounds, the forms to be classed as unstable usually possess much less stability, but still of course they are not altogether destitute of it. This persistence in a state no longer completely stable may be explained by supposing that a certain impulse, or an increase of the proper motion of the particles, is required to change the state—to make the particles leave their respective positions and pass over into new ones. That the change is attained most easily and most surely by contact with a crystal of the stable modification, is undoubtedly due to the power of every crystal to give to the particles settling on it a definite and regular orientation and arrangement. L. M.

ALLOXAN $C_4H_2N_2O_4$ aq (and 4aq.)

i.e.
$CO<\begin{smallmatrix}NH.CO\\NH.CO\end{smallmatrix}>CO$. *Mesoxalyl-urea.* Mol. w. 142.—Discovered in 1817 by Brugnatelli, who named it erythric acid. Subsequently examined by Liebig a. Wöhler (*A.* 26, 256), and by Schlieper (*A.* 55, 253).

Formation.—1. By oxidation of uric acid by HNO_3 (S.G. 1·42) diluted with water (9 pts.) at 70°. By adding $SnCl_2$, alloxantin is ppd., and, after washing, is re-oxidised to alloxan by nitric acid (2 pts. of S.G. 1·52 mixed with 1 pt. of S.G. 1·42) in the cold (Liebig, *A.* 147, 366, *Bl.* [2] 9, 152).—2. From uric acid and aqueous Br, Cl, or I (M. E. Hardy, *Bl.* [2] 1, 445).—3. From xanthine, $KClO_3$, and HCl (E. Fischer, *A.* 215, 310).

Properties.—A warm saturated aqueous solution deposits on cooling trimetric efflorescent crystals (with 4aq). If the solution is kept warm while evaporating monoclinic prisms (with aq) are got. V. sol. water or alcohol, ppd. from solution by HNO_3. Astringent taste, reddens litmus, does not decompose $CaCO_3$. Aqueous solution turns the skin purple, imparting a peculiar smell.

Reactions.—1. Hot dilute *nitric acid* forms CO_2 and parabanic acid, the latter then becoming CO_2 and urea.—2. Boiling *potash* forms mesoxalic acid and urea.—3. Boiling very dilute *sulphuric acid* forms ammonic hydurilate.—4. Boiling aqueous HCl or H_2SO_4 forms alloxantin, which separates; dialuric acid, ammonic oxalate etc., remain in solution.—5. Boiled a long time with *water*, it forms CO_2, parabanic acid, and alloxantin.—6. By *reducing agents* (H_2S, $SnCl_2$, Zn and HCl) it is converted into alloxantin, and finally into dialuric acid.—7. Boiled with *ammonia and sulphurous acid*, it forms ammonic thionurate (*q. v.*).—8. KHO or *baryta* converts it into alloxanic acid; baryta or lime-water giving white pps. of baric or calcic alloxanate. If the alkali be in excess, the pp. contains mesoxalate. 9. Warm aqueous *ammonia* forms a yellow jelly of the ammonium salt of 'mycomelic acid' $C_4H_4N_4O_2$ (L. a. W.).—10. *Ferrous sulphate* gives a deep blue colour.—11. Boiled with water and PbO_2 there results CO_2, $PbCO_3$, and urea.—12. Boiling aqueous *lead acetate* forms lead mesoxalate and urea.—13. Boiling aqueous $NaNO_2$ and acetic acid form sodic oxalurate (Gibbs, *Am. S.* [2] 48, 215).—14. *Hydroxylamine hydrochloride* forms violuric acid.—15. With a dilute solution of *pyrrol* it forms crystalline pyrrol-alloxan (Ciamician a. Silber, *B.* 19, 106, 1708).—16. PCl_5 mixed with $POCl_3$ at 130° forms tetra-chloro-pyrimidine (Ciamician a. Magnaghi, *B.* 18, 3444).

Metallic derivatives. — $C_4Ag_2N_2O_4$.— $C_4H_2N_2O_4HgO$ 7aq: ppd. by mercuric nitrate.—

Compounds with Bisulphites.— $C_4H_2N_2O_4NaHSO_3 1\frac{1}{2}$aq: large crystals, v. sol. water.—$C_4H_2N_2O_4KHSO_3$ aq: m. sol. cold water, v. sol. hot water.—$C_4H_2N_2O_4NH_4HSO_3$ (Limpricht a. Wuth, *A.* 108, 41).

ALLOXANIC ACID $C_4H_4N_2O_5$ *i.e.* $NH_2.CO.NH.CO.CO.CO_2H$. *Mesoxaloxyl-urea.* S. (alcohol) about 20. (Liebig a. Wöhler, *A.* 26, 292; Schlieper, *A.* 55, 263; 56, 1; Städeler, *A.* 97, 122; Baeyer, *A.* 119, 126; 130, 159). Formed from alloxan by treatment with aqueous fixed alkalis or alkaline carbonates. White needles or warty masses. V. sol. water; sl. sol. ether.

Reactions.—1. *Boiling* the aqueous solution produces CO_2, leucoturic acid (*q. v.*), allanturic acid and hydantoïn.—2. Alloxanates are converted by *boiling water* into mesoxalates and urea.—3. *Nitric acid* forms CO_2 and parabanic acid.—4. HI reduces it to hydantoïn, giving off CO_2 (Baeyer).

Salts. The alkaline alloxanates are soluble in water. The normal salts of other metals are usually insoluble. Ferrous sulphate gives a dark blue pp. with potassic alloxanate. $NH_4C_4H_3N_2O_5$. S. about 30.—$BaH_2A''_2$2aq.—BaA''4aq.—$CaH_2A''_2$6aq. S. 5.—CaA''5aq.—CuA''4aq. S. 17 to 20.—$CuA''Cu(OH)_2$.—$PbH_2A''_2$2aq.—$Pb_3H_2A''_4$7aq.—PbA''aq.—$Pb_3A''_2(OH)_2$.—MgA''5aq.—NiA''2aq.—KHA''.—K_2A''3aq.—Ag_2A''.—SrA''4aq.—$ZnH_2A''_2$4aq.—$Zn_3OA''_2$8aq.

Iso-alloxanic acid $C_4H_4N_2O_5$. Obtained by the action of alkalis upon the red substance got by heating alloxan at 260° (L. Hardy, *A. Ch.* [4] 2, 372). A similar body may be got by the action of bromine-water on uric acid (Magnier de la Source, *Bl.* [2] 22, 56). Its solution then gives with baryta-water a splendid violet pp. of baric iso-alloxanate, which, however, when exposed to moist air soon changes to colourless baric alloxanate.

Salts.—$(NH_4)_2A''$: red powder: v. sol. water forming a purple solution, which gives with $AgNO_3$ an indigo blue pp., and with K_2CO_3 a violet colour.

ALLOXANTIN $C_8H_4N_4O_7$ 3aq.

(Liebig a. Wöhler, *A.* 26, 262; Fritzsche, ***J. pr.*** 14, 237).

Formation.—1. By action of warm dilute HNO_3 on uric acid.—2. By action of electrolysis or of reducing agents on alloxan (*q. v.*).—3. By dissolving alloxan in a concentrated aqueous solution of dialuric acid: $C_4H_2N_2O_4 + C_4H_4N_2O_4 = C_8H_4N_4O_7 + H_2O$.—4. By heating uranil or ammonium thionurate with dilute H_2SO_4.—5. By action of air on dialuric acid.—6. In the decomposition of caffeïne by chlorine.—7. By heating a mixture of malonic acid and urea with excess of $POCl_3$ (Grimaux, *C. R.* 87, 752; 88, 8[illegible]).—8. By the prolonged action of H_2S upon di-bromo-barbituric acid (G.).

Properties.—Small oblique rhombic prisms.

Reddens litmus. V. sl. sol. cold water. Gives with baryta-water a violet pp. Reduces $AgNO_3$.

Reactions.—1. At 170° gives hydurilic acid, oxalic acid, CO_2, CO, and NH_3.—2. *Oxidation* gives alloxan.—3. *Reduction* forms dialuric acid.—4. *Ammonia gas* turns it red, forming murexide.—5. *Aqueous ammonia* forms a purple solution, long boiling bleaches it, uramil being formed. This is then converted into murexide by atmospheric oxidation.—6. The purple pp. produced by *baryta-water* disappears on boiling, baric alloxanate and dialurate being formed.

ALLOYS.—The word *alloy* was originally employed to designate the product obtained by mixing gold or silver with other metals; its application is now general, all mixtures or compounds of metals with each other being named alloys, except those containing mercury, which are termed 'amalgams.' For a detailed description of special alloys, reference must be made to one of the constituent metals; only the general properties of the alloys will be here considered.

On melting two metals together, or on melting one and adding the other, complete assimilation takes place in some cases and not in others. Thus, silver easily mixes or alloys with gold, copper, or lead; but neither silver nor copper can be readily induced to unite with iron. In the cases of those metals which do not completely mix when melted together it usually happens that a small quantity of one is taken up by the other; thus, Faraday and Stodart found that iron is able to absorb $\frac{1}{500}$th of its weight of silver with production of a homogeneous alloy, the properties of which are considerably different from those of iron; but that if more silver than $\frac{1}{500}$th of the mass of the iron is present, the greater part of the silver separates during cooling, and that which remains can be detected by the microscope. If silver is melted with addition of a small quantity of iron, the latter metal alloys to some extent; but it is impossible to obtain mixtures of these metals in any desired proportion. On the other hand, silver and copper, or silver and gold, form alloys in which the proportion of the two metals may be varied at will.

The physical properties of alloys are in some cases nearly the mean of those of their constituent metals; but in other cases a wide difference is observable between the properties of the alloy and the properties of the metals which have been used to form it. Matthiessen, to whom we owe most of our knowledge of the properties of alloys, divides all metals into two classes: (1) those which impart to an alloy their own physical properties, to a less or greater degree, according to the proportion in which they themselves exist in the alloy; and (2) those which do not come under class (1). To the first class belong the metals lead, tin, zinc, and cadmium; and to the second, in all probability, the other metals. The alloys themselves may also be divided into three groups: (*a*) those made of the metals belonging to class (1), (*b*) those made of metals of class (1) with class (2); and (*c*) those made of class (2) with one another. This classification is largely based on the relative conductivity for electricity of the metals and of the alloys which they form with each other. Matthiessen found that the metals placed in class (1), when alloyed with each other, give products the conducting powers of which for heat and for electricity are proportional to the relative quantities by volume of the constituent metals; but that this is not the case with alloys of the metals of class (1) with those of class (2), nor with the alloys of metals of class (2) with each other. As regards conductivity for heat and for electricity, Wiedemann and Franz have added to our knowledge by showing that the conducting powers of metals and their alloys for heat vary in a similar manner to that in which their conductivity for electricity varies. This statement has been confirmed and amplified by Sundall.

Matthiessen regards alloys of the metals of class (1) as solidified solutions of one metal in the other; but supposes that metals of class (2) enter into alloys in an allotropic form; and he further supposes that when metals are alloyed together one or more of the metals may undergo allotropic change. Thus, he regards as solidified solutions of the metals, alloys of lead with tin, cadmium with tin, zinc with tin, cadmium with lead, zinc with cadmium, and zinc with lead. He supposes that in the alloys of lead or tin with bismuth, tin or zinc with copper or with silver, one metal is dissolved in an allotropic modification of the other; and that in alloys of bismuth with gold or silver, palladium or platinum with silver, or of gold with copper or silver, both metals exist in allotropic forms. Matthiessen does not, however, ignore the fact that certain alloys contain their constituent metals in simple atomic proportions; for example, the alloys whose composition may be expressed by the formulæ $AuSn_5$, $AuSn_2$, and $AuSn$; but he regards alloys of intermediate composition as solidified solutions of such definite compounds in each other. It is known that zinc will not alloy with more than 1·2 p.c. of lead, nor will lead alloy with more than 1·6 p.c. of zinc; yet, by stirring, it is possible to obtain mechanical mixtures of such alloys with excess of one or other metal. Such mixtures are placed by Matthiessen in a class by themselves. Most of the alloys of silver and copper with each other are regarded by him as mixtures of various solidified solutions. The hypothesis of the existence in an alloy of one of the constituent metals in an allotropic form has received a certain degree of confirmation from experiments by Deville and Debray, who have observed that the iridium separated by the action of an acid on an alloy of that metal with zinc explodes when heated to 300°, and is changed by the explosion into ordinary iridium. Wiedemann has suggested that the contraction of alloys after solidification, which sometimes goes on for days, is due to the gradual occurrence of an allotropic change in the constituent metals, one modification being stable at high, and the other at low, temperatures. If the hypothesis of the occurrence of allotropic change during the formation of certain alloys is tenable, it is remarkable that such allotropic modifications of metals should be producible by pressure; for Spring has succeeded in producing Wood's alloy (containing bismuth, cadmium, and tin), and also brass, but the latter only partially, by exposing mixtures of the metals in fine powder to very high pressures.

On the whole, there appears to be a marked analogy between alloys and solutions. It is well known that the conductivity of water for electricity is nearly nil, but becomes considerable when the minutest trace of any salt is dissolved in it. Similarly, the conductivity of copper is greatly diminished by the admixture with it of minute quantities of other metals. Moreover, in many other cases a great modification is produced in the tenacity, malleability, &c., of metals by very small additions of foreign substances; as, for example, by the addition of small quantities of carbon, silicon, sulphur, or phosphorus, to iron, of phosphorus to copper, or of magnesium to nickel. And just as an aqueous solution of a salt must be heated to a temperature higher than that of the boiling-point of water before the whole of the water is removed, so it has been found that alloys of zinc, sodium, mercury, &c., must be heated to temperatures above those at which these metals volatilise before the metals in question are entirely removed from the alloys. The analogy between alloys and solutions has been strikingly shown by Guthrie. This physicist has found that that alloy of two metals which has the lowest melting-point does not contain the metals in atomic proportion, but is strikingly similar to an 'alloy' of two salts, such as that of nitrate of potassium and nitrate of lead. Alloys were obtained by him of bismuth and zinc (Bi = 92·85 p.c. Zn = 7·15 p.c.), melting at 248°; of bismuth and tin (Bi = 46·1 p.c. Sn = 53·9 p.c.), melting at 133°; of bismuth and lead (Bi = 55·58 p.c. Pb = 44·42 p.c.), melting at 122·7°; and of bismuth and cadmium (Bi = 59·19 p.c. Cd = 40·81 p.c.), melting at 144°. None of these alloys contains the metals in the proportion of their atomic weights, and the melting-point of each alloy is the lowest of all possible alloys of the specified pair of metals. Such alloys are termed by Guthrie *eutectic* alloys; they appear to be in some sense solidified solutions, resembling cryohydrates. We are still ignorant of the true nature of such mixtures, if mixtures they be.

Spring (*B.* 15, 595) has prepared several alloys by subjecting mixtures of the constituent metals to pressures of about 7,000 atmos. In this way he obtained brass, Wood's alloy (Bi, Cd, and Sn), and Rose's alloy (Bi, Pb, and Sn).

W. R.

ALLURANIC ACID $C_5H_4N_4O_4$ (?). Formed by evaporating an aqueous solution of equivalent quantities of urea and alloxan (Mulder, *B.* 6, 1012). Crystals; sl. sol. water. AgA′2aq.

ALLYL.—The radicle $CH_2{:}CH.CH_2$ is called Allyl, the isomeric radicle $CH_3.CH{:}CH$ being termed Propenyl.

DI-ALLYL C_6H_{10} *i.e.* $CH_2{:}CH.CH_2.CH_2.CH{:}CH_2$. *Hexinene.* Mol. w. 82. (59·3°) at 769 mm. (R. Schiff, *A.* 220, 91); (59·5°) (Zander, *A.* 214, 148). S.G. $\frac{11\cdot9}{4}$ ·6983; $\frac{0}{0}$ ·7074 (Z.); $\frac{20}{4}$ ·688 (Brühl). C.E. (0°–10°) ·00138; (11·9°–59·3°) ·00156. S.V. 125·8 (S.); 125·7 (Z.). V.D. 2·84 (for 2·84). H.F.p. − 9260. H.F.v. − 11580 (Thomsen). μ_β 1·4079. R_∞ 45·99 (B.). *Critical temperature* 234·4°.

Formation.—1. From allyl iodide and Na (Berthelot a. de Luca, *A.* 100, 361), an alloy of sodium and tin (Würtz a. Leclanché, *A. Ch.* [4] 3, 155), or iron (Linnemann, *Bl.* [2] 7, 424).—2. By heating mercury allyl iodide, $IHgC_3H_5$, alone (Linnemann, *A.* 140, 180) or with aqueous KCy (Oppenheim, *B.* 4, 672).

Reactions.—1. Oxidised by *chromic acid mixture* gives carbonic and acetic acids.—2. Oxidised by $KMnO_4$ in neutral solution gives CO_2, acetic, oxalic, and succinic acids.—3. Oxidised by $KMnO_4$ in acid solution gives CO_2, acetic acid, and succinic acid (E. Sorokin, *J. pr.* 131, 1).

Constitution.—The formation of acetic acid by oxidation of di-allyl seems to favour the formula $CH_3.CH{:}CH.CH{:}CH.CH_3$; while the formation of succinic acid is more in accordance with the formula $CH_2{:}CH.CH_2.CH_2.CH{:}CH_2$, a formula that is further supported by the conversion of di-allyl into di-propargyl. The oxalic acid may be supposed to be formed by oxidation of the succinic acid. Acetic acid may be considered to be formed from intermediate hydrates,

$$CH_3.CH(OH).CH_2.CH_2.CH{:}CH_2$$

and $CH_3.CH(OH).CH_2.CH_2.CH(OH).CH_3$.

These bodies do, in fact, yield acetic acid when oxidised. According to Sabaneeff (*J. R.* 1885, 35) di-allyl forms two tetrabromides and must therefore be a mixture of two hydrocarbons.

Combinations.—1. When gaseous HI is passed into strongly cooled di-allyl, combination takes place, the product $CH_3.CHI.CH_2.CH_2.CHI.CH_3$ being formed, *v.* IODO-HEXANES.—2. A smaller quantity of HI forms the mono-hydro-iodide, $C_6H_{10}HI$, (165°), also formed from preceding by alcoholic KOH (*v.* IODO-HEXYLENE).—3. Similarly, fuming HCl forms two hydrochlorides.—4. HOCl forms $C_6H_{10}(HOCl)_2$, di-chloro-di-oxy-hexane (*q. v.*).—5. Br forms tetra-bromo-hexane.

ALLYL ACETATE $C_5H_8O_2$ *i.e.* $C_3H_5C_2H_3O_2$. Mol. w. 100. (103°–103·5°) at 735 mm. (R. Schiff, *A.* 220, 109), S.G. $\frac{20}{4}$ ·9276 (Brühl). S.V. 121·37 (S.). μ_β 1·4106. R_∞ 42·21 (B.).

ALLYL-ACETIC ACID

$C_5H_8O_2$ *i.e.* $CH_2{:}CH.CH_2.CH_2.CO_2H$. *Pentenoic acid.* (185°–188° cor.). S.G. $\frac{12}{12}$ ·9866; $\frac{15}{15}$ ·9842; $\frac{25}{25}$ ·9767. M.M. 6·426 at 14° (Perkin, *C. J.* 49, 211). Prepared by heating allyl-malonic acid (Conrad a. Bischoff, *B.* 13, 598) or from allyl-aceto-acetic ether (Zeidler, *B.* 8, 1035). Combines with Br_2 or HBr. Not reduced by *sodium-amalgam.* Oxidised by chromic acid to succinic and formic acids.

Salts.—KA′: scales; v. sol. water; solution not ppd. by Fe_2Cl_6.—CaA′$_2$ 2aq.: laminæ.—BaA′$_2$ 2aq.—AgA′ (Messerschmidt, *A.* 208, 92).

Ether.—EtA′: (142°–144°).

DI-ALLYL-ACETIC ACID $C_8H_{12}O_2$ *i.e.* $(C_3H_5)_2CH.CO_2H$. *Octinoic acid.* (220°) (C. a. B.); (218°-222°) (H.); (224°-226°) (R.); (227° cor.). S.G. $\frac{12}{12}$ ·9576; $\frac{15}{15}$ ·9555; $\frac{25}{25}$ ·9491. M.M. 10·344 at 16·4° (Perkin, *C. J.* 49, 212).

Formation.—From di-allyl-aceto-acetic ether (Wolff, *A.* 201, 49; Reboul, *Bl.* [2] 29, 228) or from di-allyl-malonic acid (Conrad a. Bischoff, *R.* 13, 598). From iodo-di-allyl-acetic acid (*q. v.*) by reduction (Schatzky, *J. R.* 17, 79).

Properties. — Oil, of disagreeable odour. Insol. water. Volatile with steam.

Reactions.—1. Conc. HBr forms, probably, an addition product $(CH_3.CHBr.CH_2)_2CH.CO_2H$ which instantly splits off HBr forming

$$CH_3.CHBr.CH_2.CH\left\langle\begin{array}{l}CH_2.CH.CH_3\\ \qquad\quad\;|\\ CO.O\end{array}\right.$$

v. BROMO-OXY-OCTOIC ACID (Hjelt, *A.* 216, 73).—2. Br in $CHCl_3$ forms, probably, an addition compound, $(CH_2Br.CHBr.CH_2)_2CH.CO_2H$, but this instantly splits up into HBr and a lactone

$$CH_2Br.CHBr.CH_2.CH\left\langle\begin{array}{l}CH_2.CH.CH_2Br\\ \qquad\quad\;|\\ CO.O\end{array}\right.$$

v. Tri-BROMO-OXY-OCTOIC ACID.

—3. HNO_3 (S.G 1·3) forms tri-carballylic acid (W.).

Salts.—CaA'_2 2aq: leaflets.—AgA'. S. ·41 at 15°. Ether.—EtA' (195°) (R.).

ALLYL-ACETO-ACETIC ETHER *v.* pp. 23, 25.

ALLYL-ACETONE

$C_6H_{10}O$ *i.e.* $CH_2:CH.CH_2.CH_2.CO.CH_3$

Methyl butenyl ketone. (129°). S.G. $\frac{27}{17\cdot5}$ ·834. From allyl-aceto-acetic ether (Zeidler, *A.* 187, 35). Unpleasant smell. Forms with $NaHSO_3$ an amorphous compound, $C_6H_{10}O\,2NaHSO_3$ (O. Hofmann, *A.* 201, 81). Reduced by sodium-amalgam to hexenyl alcohol (*q. v.*).

DI-ALLYL-ACETONE

$C_9H_{14}O$ *i.e.* $(C_3H_5)_2CH.CO.CH_3$. (175°).

From di-allyl-aceto-acetic ether (Wolff, *A.* 201, 47).

ALLYL-ACETOPHENONE *v.* PHENYL BUTENYL KETONE.

ALLYL-ACETOXIM

$C_6H_{11}ON$ *i.e.* $C_3H_5.CH_2.C(N.OH).CH_3$ (188° corr.). Formed by the action of hydroxylamine on allyl-acetone. Liquid. Soluble in alcohol, ether, benzene, CS_2, ligroine, acids, and alkalis. By aqueous acids it is resolved into its constituents. It combines with bromine to form a di-bromide (Nageli, *B.* 16, 496).

ALLYL ALCOHOL

C_3H_6O *i.e.* $CH_2:CH.CH_2OH$. [–50°]. (96·6°). S.G. $\frac{0}{0}$ ·8706; $\frac{15}{15\cdot5}$ ·8576. S.V. 74·19. C.E. (0°–20°) ·00104 (Thorpe, *C. J.* 37, 208). S.H. ·6569 (Reis, *P.* [2] 13, 447). H.F.p. 31,200. H.F.v. 29,750. R∞ 27·09 (Brühl, *A.* 200, 175).

Occurrence.—Crude wood spirit contains not more than one-fifth per cent. (Aronheim, *B.* 7, 1381; Grodzki a. Krämer, *B.* 7, 1492).

Formation. — 1. Dry gaseous ammonia is passed into oxalate of allyl till a solid mass of oxamide, saturated with allyl alcohol, is obtained. The latter is then distilled off (Zinin, *A.* 96, 362).—2. Produced, together with isopropyl alcohol and acropinacone (*q. v.*), when acroleïn is treated with zinc and hydrochloric acid (Linnemann, *A. Suppl.* 3, 257).—3. By the action of sodium on dichlorhydrin (Hübner a. Müller, *Z.* 6, 344). — 4. The two atoms of chlorine may also be removed from dichlorhydrin by sodium-amalgam (Lourenço, *A. Ch.* [3] 67, 323), or by copper and potassic iodide (Swarts, *Z.* 1868, 259).—5. Allyl iodide (1 pt.) is heated with water (20 pts.) for 60 hours in a soda-water bottle at 100°. The yield is excellent (Niederist, *A.* 196, 350).

Preparation.—Glycerine (400 pts.) is slowly distilled with crystallised oxalic acid (100 pts.) and a little ammonic chloride (1 pt.), to convert any potassic oxalate into chloride. The receiver is changed at 190°, and the distillation continued up to 260°. The distillate, containing aqueous allyl alcohol, allyl formate, acroleïn, and glycerin, is rectified, dried, first with K_2CO_3, then over solid potash, and distilled. It then boils at 90°, but when the last traces of water are removed by quicklime, it boils at 96°. The yield is one-fifth of the weight of oxalic acid used (Tollens a. Henninger, *Bl.* [2] 9, 394; Brühl, *A.* 200, 174; Linnemann, *B.* 7, 854).

Theory of the Process. — Carbonic acid is first evolved freely (at 130°), but formic acid which must be produced at the same time ($H_2C_2O_4 = CO_2 + H_2CO_2$) reacts upon glycerin, producing monoformin: $C_3H_5(OH)_3 + H_2CO_2 = H_2O + C_3H_5(OH)_2(OCHO)$. The monoformin can be extracted with ether, and boils about 165° *in vacuo.* When distilled, monoformin splits up into allyl alcohol and carbonic acid:

$$C_3H_5(OH)_2(OCHO) = CO_2 + H_2O + C_3H_5(OH)$$

(Tollens, *A.* 156, 140). When a large quantity of oxalic acid is used, the excess of formic acid does not produce diformin, but comes off as formic acid (*q. v.*).

Properties.—A pungent liquid, with a burning taste. It mixes with water, alcohol, and ether.

Constitution.—That allyl alcohol has the formula $CH_2:CH.CH_2OH$ and not $CH_3.CH:CH.OH$ may be inferred from the fact that it yields no acetic acid when oxidised by nitric acid. A similar remark applies to allyl iodide (Kekulé a. Rinne, *B.* 6, 386).

Reactions.—1. *Chromic acid* oxidises it to CO_2 and formic acid; no acrylic acid is formed, but a pungent odour, which may be due to acroleïn, is observed (Hofmann a. Cahours, *A.* 100, 257; Rinne a. Tollens, *A.* 159, 110).—2. When allyl alcohol is heated, with inverted condenser, for 5 hours in a water-bath with *zinc* and dilute H_2SO_4, about 16 p.c. is reduced to *n*-propyl alcohol: $CH_2:CH.CH_2OH + H_2 = CH_3.CH_2.CH_2OH$ (Linnemann, *B.* 7, 862).—3. Solid *potash* at 100°–150°, in a flask with inverted condenser, forms *n*-propyl alcohol (by reduction), formic acid (by oxidation), ethyl alcohol, hydrogen, and other products (Tollens, *A.* 159, 92).—4. *Potassium* displaces hydrogen, forming gelatinous potassic allylate.—5. H_2SO_4 forms $(C_3H_5)HSO_4$.—6. Dilute H_2SO_4 or HCl at 100° forms an aldehyde, $C_6H_{10}O$ (c. 137°) (Solonina, *J. R.* 1885, i. 145).

Combinations.—1. With *chlorine* it forms *u*-dichlorhydrin $CH_2Cl.CHCl.CH_2OH$ (*q. v.*)—2. With *bromine* it forms a dibromide, called also dibromhydrin, $CH_2Br.CHBr.CH_2OH$, (214°). 60 grms. Br are dissolved in 300 grms. CS_2 and dropped slowly (in 4 hours) into a solution of 20 grms. of allyl alcohol in 100 grms. of CS_2. The product is distilled in vacuo (Michael a. Norton, *Am.* 2, 16; compare Kekulé, *A. Suppl.* 1, 138; Markownikoff, *J.* 1864, 490). Linnemann says there are two bromides (*B.* 7, 859).—3. When *iodine* is added to a solution of allyl alcohol in $CHCl_3$, it combines, and on evaporatine $CH_2I.CHI.CH_2OH$ separates as needles. Dilute Na_2CO_3 converts this into iodallyl alcohol [160°] (Hübner a. Lellmann, *B.* 14, 207).—4. ICl unites, forming $C_3H_5ICl(OH)$ (Henry, *B.* 3, 851).—5. With *cyanogen* it unites, forming $C_3H_5(CN)_2(OH)$, (151°) (Tollens, *B.* 5, 1045).—6. BaO combines, forming $BaO,2C_3H_6O$.—7. HClO unites, forming a little chlorhydrin (*q. v.*).—8. *Chloral* combines with allyl alcohol; the compound, $CCl_3.CH(OH)(OC_3H_5)$ [20·5°], (116°), is analogous to chloral alcoholate (Oglialoro, *G.* 4, 463).

DI-ALLYL-*p*-AMIDO-BENZOIC ACID $C_{13}H_{15}NO_2$ *i.e.* $(C_3H_5)_2N.C_6H_4.CO_2H$ [127°]. From allyl iodide and potassic *p*-amido-benzoate (Michael a. Wing, *Am.* 7, 198).

Di-allyl-*m*-amido-benzoic acid [90°] (Griess, *B.* 5, 1041).—HA'HCl aq.

DI-ALLYL-AMIDO-ETHYL ALCOHOL *v.* OXYETHYL-DI-ALLYLAMINE.

ALLYLAMINE C_3H_7N *i.e.* $CH_2:CH.CH_2.NH_2$ Mol. w. 57. (56°) (R. Schiff, *B.* 19, 565); (58°) (Oeser, *A.* 134, 7). S.G. ^{15} ·864 (O.) S.V. 78·38 (S.). H.F.p. – 1140. H.F.v. – 2880.

Formation.—1. From allyl cyanate (Cahours a. Hofmann, *A.* 102, 301).—2. From oil of mustard, Zn, and HCl (O.).—3. From oil of mustard and conc. H_2SO_4 (Hofmann, *B.* 1, 182; Rinne, *A.* 168, 262).

Properties.—Liquid with pungent ammoniacal odour. Miscible with water. Strong base. Dissolves ppd. $Cu(OH)_2$ and Ag_2O.

Reactions.—1. Combines with bromine.—2. H_2SO_4 at 140° forms a compound which, on pouring into water, produces oxy-propyl-amine $HO.C_3H_6.NH_2$.

Salts.—$(B'HCl)_2PtCl_4$: monoclinic tables. Changed by boiling into $(B'HCl)_2PtCl_2$ (Liebermann a. Paal, *B.* 16, 530).—$B'_2H_2SO_4$ (Andreasch, *M.* 5, 33).

Di-allyl-amine $C_6H_{11}N$ *i.e.* $(C_3H_5)_2NH$ (111°) (Ladenburg, *B.* 14, 1879).

Tri-allyl-amine $C_9H_{15}N$ *i.e.* $(C_3H_5)_3N$. (156° i.V.) S.G. $\frac{0}{0}$ ·8206. S.V. 200·3 (Zander). C.E. (0°–10°) ·00103. Formed when tetra-allyl-ammonium hydroxide is distilled (C. a. H.; Pinner, *B.* 12, 2054; Grosheintz, *Bl.* 31, 391).—$B'HCl$.—$B'_2H_2PtCl_6$.

Tetra-allyl-ammonium hydrate $(C_3H_5)_4NOH$: liquid. — $((C_3H_5)_4NCl)_2PtCl_4$. — $(C_3H_5)_4NBr$. — $(C_3H_5)_4NI$. The three last are crystalline (C. a. H.).

ALLYL-AMYL-AMINE $C_8H_{17}N$ *i.e.* $(C_3H_5)(C_5H_{11})NH$. (c. 150°). S.G. $\frac{18}{18}$ ·777. From amyl bromide and allyl-amine (Liebermann a. Paal, *B.* 16, 531).

ALLYL AMYL OXIDE $C_8H_{16}O$ *i.e.* $C_5H_{11}.O.C_3H_5$ (120°) (Berthelot a. de Luca, *A. Ch.* [3] 48, 292).

ALLYL-ANILINE $C_9H_{11}N$ *i.e.* $PhN(C_3H_5)H$. (209°). S.G. ^{25} ·982 (Schiff, *A. Suppl.* 3, 364).

Di-allyl-aniline $C_{12}H_{15}N$ *i.e.* $PhN(C_3H_5)_2$. (244°). S.G. $\frac{0}{0}$ ·9680. S.V. 225·2 (Zander, *A.* 214, 149). C. E. (0°–10°) ·00083.

ALLYL-BENZENE C_9H_{10} *i.e.* $Ph.CH:CH.CH_3$(?) *Phenyl-propylene. Propenyl-benzene.* Mol. w. 118. (175°) (P.); (178°) (E.). S.G. ^{15} ·92.

Formation. — 1. By-product in action of sodium-amalgam on warm aqueous cinnamyl alcohol (Fittig a. Krügener, *B.* 6, 214; Rügheimer, *A.* 172, 129).—2. From propyl-benzene by Br at 160° and distilling the product (Radziszewski, *C. R.* 78, 1153): $PhC_3H_6Br = PhC_3H_5 + HBr$. So prepared it boils at (165°), and its di-bromide forms needles.—3. From bromo-hydro-phenyl-crotonic acid (Perkin, *C. J.* 32, 660).—4. From chloro-propyl-benzene and alcoholic potash (Errera, *G.* 14, 504).

Di-bromide $C_9H_{10}Br_2$ [66·5°]. Plates or needles. On distillation it yields an allyl-benzene (178°), which polymerises forming a viscid solid (330°).

Iso-allyl-benzene $Ph.CH_2.CH:CH_2$(?) (155°). Chojnacki (*C. R.* 76, 1413) got this body from allyl iodide or bromide, benzene, and zinc dust at 100°. Others have failed to get it. Allyl chloride, benzene, and Al_2Cl_6 give di-phenyl propane, $CH_3.CHPh.CH_2Ph$, and *n*-propyl-benzene (*q. v.*) (Wispek a. Zuber, *A.* 218, 378).

ALLYL BENZOATE *v.* BENZOIC ACID.

ALLYL-BENZOYL-ACETIC ACID $C_{12}H_{12}O_3$ *i.e.* $BzCH(C_3H_5)CO_2H$ [122°–125°]. From benzoyl-acetic ether, NaOEt, and allyl iodide. The resulting ether is saponified by standing for three weeks with dilute alcoholic KOH (W. H. Perkin, jun., *C. J.* 45, 186; 47, 240). Colourless crystals.

Reaction.—Boiled with dilute alcoholic KOH forms phenyl butenyl ketone (*q. v.*), benzoic acid and (probably) allyl-acetic acid.

Ether.—EtA' (220°) at 100 mm.; (241°) at 225 mm. Combines with Br.

ALLYL BORATE $C_9H_{15}BO_3$ *i.e.* $(C_3H_5)_3BO_3$ (168°–175°). From B_2O_3 and allyl alcohol at 130° (Councler, *J. pr.* [2] 18, 376). Combines with bromine, forming $(C_3H_5Br_2)_3BO_3$.

ALLYL BROMIDE C_3H_5Br *i.e.* $CH_2:CH.CH_2Br$ (71°). S.G. $\frac{0}{0}$ 1·459; ^{15} 1·436. S.V. 90·5 (Zander, *A.* 214, 144). C E. (0°–10°) ·00123. H.F.p. –340; H.F.v. –1500.

Formation.—1. From allyl alcohol, bromine, and phosphorus (Tollens, *A.* 156, 152).—2. From glycerine and PBr_3 (Henry, *Z.* [2] 6, 575).—3. From allyl iodide and cupric bromide: $2C_3H_5I + 2CuBr_2 = Br_2 + Cu_2I_2 + 2C_3H_5Br$ (Oppenheim, *B.* 3, 442).

Preparation.—Potassic bromide, hydric sulphate (2 pts.), and water (1 pt.) are warmed till hydric bromide begins to come off. Allyl alcohol is then dropped in (Grosheintz, *Bl.* 30, 98).

Combinations.—1. With concentrated *hydric bromide* forms a mixture of propylene bromide $(CH_3.CHBr.CH_2Br)$ and trimethylene bromide $(CH_2Br.CH_2.CH_2Br)$ which may be separated by distillation (Geromont, *A.* 158, 369).—2. With dry HBr it forms chiefly trimethylene bromide (*q. v.*).—3. With *bromine* it forms tribromhydrin (*q. v.*).—4. With ICl it forms C_3H_5IClBr.—5. With ClBr at 20° forms $C_3H_5ClBr_2$, but at 100° forms $C_3H_4Cl_2Br$ (M. Simpson, *Pr.* 27, 119).—6. With HClO it produces $C_3H_5(OH)BrCl$.—7. It combines with NEt_3.

ALLYL BUTYRATE *v.* BUTYRIC ACID.

ALLYL-ISO-BUTYL-MALONIC ETHER $C_{14}H_{24}O_4$ *i.e.* $(C_3H_5)C(C_4H_9)(CO_2Et)_2$ (247°–250°). From di-sodio-malonic ether, allyl iodide, and iso-butyl iodide (Ballo, *B.* 14, 335). On saponification it gives an acid [129°] which appears to be propyl-iso-butyl-malonic acid.

ALLYL CARBAMINE C_4H_5N *i.e.* $CH_2:CH.CH_2.NC$ (96°–106°). S.G. ^{17} ·794. Produced by the action of silver cyanide on allyl iodide. It is a liquid of disagreeable odour Somewhat soluble in water (Lieke. *A.* 112, 316).

DI-ALLYL CARBINOL *v.* HEPTINYL ALCOHOL.

DI-ALLYL-DI-CHLORHYDRIN $C_6H_{12}Cl_2O_2$ *i.e.* $C_6H_{10}(OH)_2Cl_2$. From HClO and di-allyl (Przybytek, *B.* 18, 1350; Lauch, *B.* 18, 2288).

ALLYL CHLORIDE C_3H_5Cl *i.e.* $CH_2:CH.CH_2Cl$ (46°) (Thorpe); (44·6°) at 744 mm. (Brühl). S.G. $\frac{0}{0}$ ·9547; $\frac{20}{4}$ ·9379 (Brühl). C.E. (0°–10°) ·00137. S.V. 84·7 (Zander). S.H. ·3984 (Reis). μ_β 1·4225. R_∞ 32·63 (Brühl). H.F.p. 7100. H.F.v. 5940. M.M. 6·008 at 19·6°.

Formation.—1. From allyl iodide and $HgCl_2$. 2. From allyl oxalate, calcic chloride, and alcohol (Oppenheim, *A.* 140, 205).—3. From allyl alcohol and HCl in sealed tubes.

Preparation.—From allyl alcohol and PCl_3 (Tollens, *A.* 156, 154).

Properties.—1. Alcoholic *potash*, even below 100°, converts it into ethyl allyl oxide. The isomeric chloropropylene (26°) is converted by alcoholic potash at 120° into allylene.—2. HClO unites, forming unsymmetrical dichlorhydrin, $CH_2Cl.CHCl.CH_2OH$, or dichloride of allyl alcohol. This body, when oxidised by HNO_3, is converted into dichloropropionic acid (Henry, *B.* 7, 757).—3. HCl combines, forming $CH_3.CHCl.CH_2Cl$.—4. HBr forms $CH_2Br.CH_2.CH_2Cl$, together with a little $CH_3.CHBr.CH_2Cl$.—5. Warmed with H_2SO_4 and then diluted and distilled, propylene chlorhydrin is produced (Oppenheim, *A. Suppl.* 6, 367).—6. *Bromine* combines, forming $C_3H_5Cl.Br_2$.—7. With *potassic cyanide* in presence of dilute alcohol it forms chiefly pyrotartaric acid, also propylene cyanide (Claus, *A.* 191, 38) and triallylamine (Pinner, *B.* 12, 2053). The reactions in this case are: (*a*) $CH_2:CH.CH_2Cl + KCN = KCl + CH_2:CH.CH_2.CN$. (*b*) $CH_2:CH.CH_2CN + HCN = CH_3.CH(CN).CH_2CN$ (*c*) $CH_3.CH(CN).CH_2CN + 2KOH + 2H_2O = 2NH_3 + CH_3.CH(CO_2K).CH_2.CO_2K$ (pyrotartrate). The liberated ammonia forms the triallylamine. 8. With *benzene*, in presence of aluminium chloride, forms diphenylpropane: $C_3H_5Cl + 2C_6H_6 = HCl + (C_6H_5)_2C_3H_6$ (Silva, *C.R.* 89, 606).

ALLYL-PSEUDO-CUMYL-PHTHAL-AMIDE. $C_{20}H_{22}N_2O_2$ *i.e.* $C_6H_2Me_3.NH.CO.C_6H_4.CO.NHC_3H_5$. [179°]. Silky needles. Easily soluble in alcohol. Formed by the action of allylamine on phthal-pseudo-cumidine (Fröhlich, *B.* 17, 1808).

ALLYL CYANAMIDE $C_4H_6O_2\,\frac{1}{2}$aq. *i.e.* $(CN.NHC_3H_5)_x$. *Sinamine* [100°]. From allyl-thio-urea and $Pb(OH)_2$ or HgO. (Will, *A.* 52, 15; Andreasch, *M.* 2, 780; Robiquet a. Bussy, *J. pr.* 19, 234). Alkaline. Sol. water, alcohol, and ether. Forms compounds with $HgCl_2$, $\frac{1}{2}PtCl_4$, and oxalic acid.

ALLYL CYANATE C_4H_5NO *i.e.* $C_3H_5N.CO$. *Allyl carbimide.* (82°). V.D. 3·05 (for 2·88). From allyl iodide and silver cyanate (Cahours a. Hofmann, *Tr.* 1857, 555).

ALLYL CYANIDE C_4H_5N *i.e.* $CH_2:CH.CH_2CN$. *Crotonitrile.* Mol. w. 67. (119° cor.). S.G. ^{0} ·8491; ^{15} ·8351; $\frac{12.9}{0}$: ·8398.

Formation.—1. By ppg. potassic myronate (*q. v.*) with silver nitrate and treating the pp. with hydric sulphide $C_4H_4Ag_2NS_2O_4 + H_2S = C_4H_5N + Ag_2S + S + H_2SO_4$.—2. During the fermentation of black mustard.—3. From allyl mustard oil by zinc dust: $C_3H_5NCS + Zn = ZnS + C_3H_5CN$ (Schwarz, *B.* 15, 2508).—4. From allyl sulphocyanide and sodium (Billeter, *B.* 8, 465).

Preparation.—Allyl iodide is heated with KCy for two days at 110°. The product is washed, dried, and heated again with KCy at 110°. It is then washed, dried over $CaCl_2$, distilled, freed from carbamine by shaking with a little HNO_3, and rectified (Rinne a. Tollens, *A.* 159, 106).

Properties.—Liquid smelling faintly of garlic.

Reactions.—1. Aqueous or alcoholic *potash* forms NH_3, and solid crotonic acid [72°]. The formation of this crotonic acid may be explained by the assumption that β-oxybutyrate is first formed: $CH_2:CH.CH_2CN + KOH + 2H_2O = NH_3 + CH_3.CH(OH).CH_2.CO_2K$, and that this splits off water: $CH_3.CH(OH).CH_2.CO_2K = H_2O + CH_3.CH:CH.CO_2K$, forming potassic crotonate. This view is supported by the behaviour of allyl cyanide towards HCl.—2. With fuming *hydric chloride* at 60° it forms β-chlorobutyric acid: $CH_2:CH.CH_2.CN + 2HCl + 2H_2O = NH_4Cl + CH_3.CHCl.CH_2.CO_2H$. This is an unstable acid, which easily changes to crotonic acid.—3. HNO_3 forms acetic and oxalic acids.—4. CrO_3 forms acetic acid.

Combinations.—1. With *alcohol.* When potassic cyanide acts on allyl iodide in alcoholic solution, a compound of allyl cyanide and alcohol, of boiling point (174°), is obtained: $CH_2:CH.CH_2CN + HOEt = CH_3.CH(OEt).CH_2.CN$. Saponified by strong HCl, this forms ethoxybutyramide, $CH_3.CH(OEt).CH_2.CONH_2$ [71°], which, when warmed with HCl, gives ethoxybutyric acid, $CH_3.CH(OEt).CH_2.CO_2H$, boiling about 215°. Saponified by potash, the compound of allyl cyanide and alcohol (β-ethoxybutyronitrile) gives ordinary crotonic acid as follows: $CH_3.CH(OEt).CH_2.CN + KOH + H_2O = NH_3 + HOEt + CH_3.CH:CH.CO_2K$ (Rinne, *B.* 6, 389). Dry hydrogen chloride converts the compound of allyl cyanide and alcohol into the chloride of β-chlorobutyrimid-ether (166°), $CH_3.CHCl.CH_2.C(OEt)NH$. This last compound is converted by alcoholic potash into crotonic acid (Pinner, *B.* 17, 2007).

2. With *allylalcohol.* A similar compound, $CH_3.CH(OC_3H_5).CH_2CN$ (96°), is formed when KCy acts on allyl chloride mixed with allyl alcohol.

Constitution.—From its mode of preparation, allyl cyanide ought to be $CH_2:CH.CH_2.CN$, but from its reaction with potash it should be the nitrile of ordinary crotonic acid $CH_3.CH:CH.CN$. From the fact that allyl cyanide and crotonic acid both produce acetic acid on oxidation, while allyl iodide and allyl alcohol yield no acetic acid, Kekulé assumes the presence of a methyl group in the two former and its absence in the two last named (*B.* 6, 386). This reasoning seemed conclusive until the experiments of Pinner, mentioned above, showed that, when the cyanide is converted into crotonic acid by hydric chloride, an intermediate compound β-chlorobutyric acid) is produced, and it is therefore possible that when nitric or chromic acid is used, an unstable derivative of butyric acid (say, β-oxybutyric acid) is first formed, and that it is this which gives acetic acid on oxidation.

ALLYLENE C_3H_4 *i.e.* Me.C:CH. *Methyl-acetylene. Propinene.* Mol. w. 40. S. (ether) 30 at 16°. H.F.p. −39950 (Thomsen); −37500 (Berthelot). H.F.v. −41530 (Th.).

Formation.—1. By action of alcoholic NaOH upon bromo-propylene (Sawitsch. *C. R.* 52, 399), chloro-propylene, or propylene bromide (Miasnikoff, *A.* 118, 332).—2. By the action of Na upon $CH_3.CCl_2.CHCl_2$ (Borsche a. Fittig, *A.* 133, 111), $CH_2Cl.CCl_2.CH_2Cl$, or $CH_2:CCl.CH_2Cl$ (Pfeffer a. Fittig, *A.* 135, 357).—3. By electrolysis of calcium mesaconate or citraconate (Aarland, *J. pr.* [2] 7, 142).—4. By heating (citra-) bromo-pyrotartaric anhydride with ammoniacal $AgNO_3Aq$ at 130° (E. Bourgoin, *C. R.* 85, 710). Colourless gas, with unpleasant smell; burns with smoky flame. V. sol. alcohol, sol. water.

Reactions.—1. Ammoniacal *cuprous chloride* gives a canary coloured pp.—2. Absorbed by conc. H_2SO_4 much more readily than acetylene, allylene sulphonic acid, $C_3H_3SO_3H$, being produced. An aqueous solution of this acid, when heated, yields mesitylene and acetone (A. Schroke, *B.* 8, 17, 367).—3. Aqueous *mercuric salts* form pps. containing the mercuric salt, HgO, and allylene. These pps. are decomposed by acids with formation of acetone (Kutscheroff, *B.* 14, 1541; *J. R.* 1882, 326).—4. $KMnO_4Aq$ forms, in the cold, malonic, oxalic, and formic acids (Berthelot, *A. Suppl.* 5, 97).—5. CrO_3Aq forms propionic acid (Berthelot, *A. Suppl.* 8, 47).

Metallic Derivatives. — $CH_3.C:CNa$: white powder, decomposed by water into NaOH and allylene (Berthelot, *A. Ch.* [4] 9, 395; *J. R.* 12, 288).—$(C_3H_3)_2Hg$: crystalline pp. formed by passing allylene into Nessler's solution (Kutscheroff, *B.* 17, 25).

Combinations.—1. Cold fuming HCl forms $CH_3.CCl_2.CH_3$; HBr, and HI act similarly.—2. *Bromine* forms di-bromo-propylene (*q. v.*) and tetra-bromo-propane (*q. v.*). *Iodine* acts similarly.

Iso-allylene $CH_2:C:CH_2$. 1. Formed by electrolysis of potassic itaconate (A.).—2. By the action of sodium on di-chloro-propylene, $CHCl:CH.CH_2Cl$ (from symmetrical tri-chlorhydrin, Hartenstein, *J. pr.* [2] 6, 295).

Properties.—A gas that does not pp. ammoniacal silver or cuprous solutions. Forms a tetrabromide.

Di-allylene C_6H_8 or $CH_2:CH.CH_2.CH_2.C:CH$ *Allyl-allylene* (70°). S.G. ^{18} ·858. V.D. 2·79 (for 2·76). Allyl-acetone is converted by PCl_5 into $C_3H_5.CH_2.CCl_2.CH_3$, which is converted by alcoholic KOH into di-allylene (L. Henry, *C. R.* 87, 171).

Reactions.—1. Aqueous *silver nitrate* gives a pp. C_6H_7Ag aq.—2. Ammoniacal *cuprous chloride* gives a canary-yellow pp. C_6H_7Cu aq.—3. Alcoholic $AgNO_3$ gives a pp. $C_6H_7AgEtOH$.—4. *Bromine* forms $C_6H_8Br_6$.

Iso-allylene tetra-carboxylic acid *v.* Propane tetra-carboxylic acid.

ALLYLENE DI-CHLORIDE *v.* Di-chloro-propylene.

ALLYLENE OXIDE C_3H_4O (63°). Formed by oxidising allylene with CrO_3Aq (Berthelot, *Bl.* 14, 116). Pungent neutral liquid. Not attacked by baryta-water at 150° or by KOHAq at 300°. Reduces $AgNO_3Aq$.

ALLYL ETHANE *v.* Pentinene.

ALLYL ETHER *v.* Allyl oxide.

ALLYL ETHYL OXIDE *v.* Ethyl allyl oxide.

DI-ALLYL HYDRATE *v.* Hexenyl alcohol.

DI-ALLYL-DI-HYDRATE *v.* Di-oxy-hexane.

ALLYLIN *v.* Glycerin.

ALLYL IODIDE C_3H_5I *i.e.* $CH_2:CH.CH_2I$ (102·7° i. V.). S.G. $\frac{0}{4}$ ·8696. C.E. ·00106. S.V. 100·9 (Zander, *A.* 214, 145); V.D. 5·77 (obs.).

Formation.—1. Allyl alcohol, P, and iodine (Tollens, *Bl.* [2] 9, 396).—2. Glycerin and PI_2 (Berthelot a. de Luca, *A. Ch.* [3] 43, 257).—3. Glycerin distilled with hydriodic acid; excess of the latter is to be avoided, as it would convert the allyl iodide into isopropyl iodide:

$$CH_2:CH.CH_2I + 2HI = CH_3.CHI.CH_2I + HI =$$
$$CH_3.CH:CH_2 + I_2 + HI = CH_3.CHI.CH_3 + I_2$$

(Erlenmeyer, *A.* 139, 211).—4. From allyl chloride and calcic iodide (Romburgh, *R.* 1, 151; Spindler, *A.* 231, 270).

Preparation.—200 grms. of glycerin, previously dried by heating to 280°, are mixed with 125 grms. of iodine. The tubulus of the retort is connected by a flexible tube with a flask containing 40 grms. of clear phosphorus in small pieces; this flask has also a side tube through which carbonic acid is passed until the air is cleared out of the entire apparatus. The clear phosphorus is added to the contents of the retort by tilting the flask from time to time. Allyl iodide distils over rapidly. The addition of phosphorus takes about 2½ hours. The distillation is then continued until the contents of the retort begin to carbonise and vapours of acroleïn are given off. The distillate is washed with dilute NaOH, dried over $CaCl_2$, and rectified. Yield 110 grms. (98°-102°).

Theory of the Process.—It is usually held that triiodhydrin is first formed:

$$CH_2(OH).CH(OH).CH_2(OH) + P + I_3 =$$
$$H_3PO_3 + CH_2I.CHI.CH_2I,$$

and that this splits up into iodine and allyl iodide: $CH_2I.CHI.CH_2I = I_2 + CH_2:CH.CH_2I$. But the fact that allyl alcohol accompanies the allyl iodide renders it quite likely that the intermediate body is diiodhydrin:

$$CH_2I.CHI.CH_2OH = I_2 + CH_2:CH.CH_2OH.$$

The allyl alcohol formed in this way being converted into iodide by HI (Henry, *B.* 14, 403).

Reactions.—1. *Zinc* and HCl reduce it to propylene.—2. Salts of *silver* form silver iodide and salts of allyl.—3. Dry *hydric iodide* converts it into isopropyl iodide (Simpson, *Pr.* 12, 533). 4. With *zinc ethyl* at 100° it forms amylene, pentane, and diallyl (Wurtz, *C. R.* 56, 387).—5. With *cacodyl* it reacts thus: $As_2Me_4 + 2C_3H_5I = AsMe_2I + AsMe_2(C_3H_5)_2I$ (Cahours, *A. Ch.* [3] 62, 291).—6. With *dry copper zinc couple* at 100° it forms diallyl: $2C_3H_5I + Zn = ZnI_2 + (C_3H_5)_2$.—7. With *wet* copper-zinc couple it forms propylene: $C_3H_5I + H_2O + Zn = IZnOH + C_3H_6$.—8. With *zinc* and alcohol (S.G. ·805) it also forms propylene (Gladstone a. Tribe, *C. J.* 27, 208).—9. With $HgBr_2$ at 200° it gives HgI_2, HBr and propane (Montgolfier a. Girand, *B.* 12, 1211).—10. Heated at 100° for a long time with *water* it forms allyl alcohol (*q. v.*).—11. With KCN and alcohol it forms a di-cyanide which, when boiled with KOH, produces potassic pyrotartrate (Claus, *A.* 191, 38).

Combinations.—1. With *chloride of iodine* it unites, forming $C_3H_5I_2Cl$ (205°-210°), a colourless oil (M. Simpson, *Pr.* 13, 540).—2. *Bromine* forms $C_3H_5Br_3$.—3. *Mercury* unites with it, forming C_3H_5HgI, mercuric-allyl iodide.

ALLYL-MALONIC ACID
$C_6H_8O_4$ *i.e.* $C_3H_5CH(CO_2H)_2$. [103°].
(Conrad a. Bischoff, *B.* 13, 597; *A.* 204, 166; Hjelt, *A.* 216, 52). Large prisms. V. sol. water, alcohol, and ether. At 180° it splits up into CO_2 and allyl-acetic acid. Combines with HBr forming liquid $(CO_2H)_2CH.C_3H_6Br$ which, when boiled with water gives a lactone of oxy-propyl-malonic acid (*q. v.*). Combines with Br_2 forming di-bromo-propyl-malonic acid (*q. v.*).

Salts.—CaA″: crystalline powder.—Ag_2A''.

Ether.—Et_2A'' (218°–225°); (194°) at 330 mm. S.G. $\frac{16}{15}$ 1·018 (C. a. B.); $\frac{15}{15}$ 1·014. M.M. 11·28 at 13·7° (Perkin). From sodio-malonic ether and allyl iodide.

Di-allyl-malonic acid
$C_9H_{12}O_4$ *i.e.* $(C_3H_5)_2C(CO_2H)_2$. [133°].
Rhombic prisms; *a*:*b*:*c* = ·9916:1:1·0179 (Haushofer, *Z. K.* 11, 147). Sol. water, alcohol, and ether; v. sl. sol. CS_2.

Reactions.—1. *Heat* splits it up into CO_2 and di-allyl-acetic acid.

Ether Et_2A''. (240°) (C. a. B.); (203°) at 225 mm. S.G. $\frac{14}{15}$ ·996 (C. a. B.); $\frac{15}{15}$ 1·000; $\frac{25}{25}$ ·993 (Perkin). M.M. 15 at 22°. From allyl iodide and sodio-malonic ether (Conrad a. Bischoff, *B.* 13, 598; *A.* 201, 171; Hjelt, *A.* 216, 61).

ALLYL MERCAPTAN C_3H_5SH. Mol. w. 74. (90°) (Hofmann a. Cahours, *A.* 102, 292).—C_3H_5SHgCl: pearly plates (from alcohol) (Gerlich, *A.* 178, 88).

ALLYL METHYL ETHER *v.* METHYL ALLYL OXIDE.

ALLYL MUSTARD OIL *v.* ALLYL THIO-CARBIMIDE.

ALLYL NITRATE $C_3H_5NO_3$. (106°). S.G. ^{10} 1·09. V.D. 3·54 (for 3·56). From allyl bromide and $AgNO_3$ (Henry, *B.* 5, 452).

ALLYL NITRITE $C_3H_5NO_2$ *i.e.* $C_3H_5.O.NO$. (44°). S.G. ^{2} ·955. Prepared by distilling glyceryl tri-nitrite with allyl alcohol. An oil. Decomposed by MeOH into allyl alcohol and methyl nitrite. Its vapour explodes at 100° (Bertoni, *G.* 15, 361).

ALLYL OXALATE *v.* OXALIC ACID.

DI-ALLYL-OXALIC ACID (so called) *v.* OXY-OCTINOIC ACID.

DI-ALLYL-OXAMIDE $C_8H_{12}N_2O_2$ *i.e.* $C_3H_5NH.CO.CO.NHC_3H_5$. [154°]. (274°). White plates. Soluble in hot water. Prepared by the action of allylamine on oxalic ether.

Tetrabromide $C_2O_2(NHC_3H_5Br_2)_2$. Insoluble in most ordinary solvents, except hot acetic acid (Wallach a. Stricker, *B.* 13, 513).

DI-ALLYL OXIDE $C_6H_{10}O$ *i.e.* $(C_3H_5)_2O$. *Allyl ether.* Mol. w. 98. (82°) (Cahours a. Hofmann, *A.* 102, 290); (94·3° i.V.) (Zander, *A.* 214, 146). S.G. $\frac{0}{0}$ ·8223. S.V. 135·5. C.E. (0°–10°) ·00127. H.F.p. 12460. H.F.v. 9850 (Thomsen).

DI-ALLYL DI-OXIDE

$$\overbrace{CH_2\,.\,CH}^{O}.CH_2.CH_2.\overbrace{CH\,.\,CH_2}^{O}$$

(180°). V.D. = 3·7 (obs.). Mobile colourless fluid of slight smell and burning taste. Heavier than water. Combines with acids, and pps. magnesia from a solution of $MgCl_2$. Obtained by the action of solid caustic alkalis upon di-allyl-di-chlorhydrin. By boiling with water it is converted into the alcohol-oxide

$$\overbrace{CH_2\,.\,CH}^{O}.CH_2.CH_2.CH(OH).CH_2(OH),$$

which only by long heating with water is converted into the tetra-hydric alcohol
$CH_2(OH).CH(OH).CH_2.CH_2.CH(OH).CH_2(OH)$ (Przybytek, *B.* 18, 1350).

o - **ALLYL - PHENOL.** *Methyl derivative* $C_{10}H_{12}O$ *i.e.* $C_6H_4(OMe).CH_2.CH:CH_2$. (233°). S.G. $\frac{15}{15}$ ·9972; $\frac{30}{30}$ ·9884; $\frac{45}{45}$ ·9793. Formed by the action of Na_2CO_3Aq on the product of the union of HI with the methyl derivative of (α)- or (β)-oxy-phenyl-crotonic acid (*q. v.*). It is an oil; combines with bromine; forms a red solid with H_2SO_4 (Perkin, *C. J.* 39, 425).

p - **Allyl-phenol.** *Methyl derivative.* (232°) S.G. $\frac{30}{30}$ ·985. Prepared as above from corresponding *p*-compound. Anethol (*q. v.*) is isomeric with this body. Anol (*q. v.*) is isomeric with allyl-phenol.

ALLYL-PHENYL-THIO-UREA $C_{10}H_{12}N_2S$ *i.e.* $C_3H_5.NH.CS.NHPh$. [98°]. S. (alcohol) 71 at 18°. From oil of mustard and aniline (Zinin, *A.* 84, 348); from allyl-amine and phenyl thio-carbimide (Weith, *B.* 8, 1529). Monoclinic crystals; v. sol. ether, insol. water. Cyanogen passed into an alcoholic solution forms $C_{10}H_{12}N_2S(CN)_2$, ppd. by water (Maly, *Z.* 1869, 261). When this is warmed with alcohol and dilute H_2SO_4 it forms the oxalyl derivative.

Oxalyl Derivative

$$\left.\begin{matrix}CO.NC_3H_5\\ |\\ CO.NC_6H_5\end{matrix}\right>CS$$

[161°]. Lemon-yellow needles, insol. water, sl. sol. cold alcohol.

ALLYL-PHENYL-UREA $C_{10}H_{12}N_2O$ *i.e.* $C_3H_5.NH.CO.NHPh$. [97°]. Needles. Got from its oxalyl derivative by baryta (Maly, *Z.* 1869, 263).

Oxalyl-derivative

$$\left.\begin{matrix}CO-NC_3H_5\\ |\\ CO-NC_6H_5\end{matrix}\right>CO.$$

From the oxalyl derivative of allyl-phenyl-thio-urea (*q. v.*) and warm $AgNO_3$ in alcoholic solution. Long needles. Insol. water, v. sol. alcohol, benzene, and CS_2.

ALLYL-PHTHALIMIDE *v.* PHTHALIC ACID, *Allylamide.*

ALLYL - PROPYL ALCOHOL *v.* HEXENYL ALCOHOL.

ALLYL-PROPYL-AMINE $C_6H_{13}N$ *i.e.* $C_3H_7NHC_3H_5$. (c. 112°). S.G. $\frac{18}{18}$ = ·7708 Colourless fluid. S. = about 6. Prepared by the action of propyl bromide on allylamine.

Salts: $B'_2H_2Cl_2PtCl_4$: orange crystals.—$B'H_2C_2O_4$: sl. sol. needles.—$B'_2H_2C_2O_4{}^{\times}$: thin plates (Liebermann a. Paal, *B.* 16, 525).

Allyl-di-propyl-amine $(C_3H_7)_2NC_3H_5$. (c. 147°). Colourless fluid. S = about 2. Formed by the action of propyl bromide on allylamine.

Salts.—$B'_2H_2Cl_2PtCl_4$: orange-red trimetric crystals, *a*:*b*:*c* = ·9831:1:1·1217. $B'HClPtCl_2$: sparingly soluble yellow needles [152°]; formed by boiling the preceding salt with water (Liebermann a. Paal, *B.* 16, 527).

ALLYL-ISO-PROPYL-BENZENE *v.* PROPENYL-ISO-PROPYL-BENZENE.

ALLYL DI-PROPYL CARBINOL *v.* DECENYL ALCOHOL.

Di-allyl propyl carbinol *v.* DECINYL ALCOHOL.

α-ALLYL-PYRIDINE $C_5H_4(C_3H_5)N$. (c. 190°).

S.G. $^{\underline{0}}$ **·9595. Colourless refractive oil; sl. sol. water. Prepared by heating pure (*a*)-picoline with paraldehyde for 10 hours at 250°-260°. On oxidation it gives picolinic acid [133°]. On reduction in alcoholic solution by means of sodium it yields (*a*)-propyl-pyridine (inactive coniine).**

Salts.—$(B'HCl)_2PtCl_4$: [186°], sparingly soluble needles.—$B'HClAuCl_3{}^{\times}$: [136°], oily pp. solidifying to small needles.—$(B'HCl)_2HgCl_2{}^{\times}$: very sparingly soluble crystalline pp. (Ladenburg, *B*. 19, 2578).

ν-**ALLYL-PYRROL** C_7H_9N *i.e.* $C_4H_4N.C_3H_5$. [105°] at 48 mm. Formed by the action of allyl bromide on pyrrol-potassium. Colourless oil. Volatile with steam. Almost insoluble in water. $HgCl_2$ gives a white pp. (Ciamician a. Dennstedt, *B*. 15, 2581; *G*. 13, 17).

ALLYL-RESORCIN $C_6H_3(C_3H_5)(OH)_2$. *Monomethyl ether* $C_6H_3(C_3H_5)(OMe)(OH)$. (245°-250°); V.D. 165 (obs.); colourless oil (Pechmann a. Cohen, *B*. 17, 2132).

ALLYL-SUCCINIC ACID

$C_7H_{10}O_4$ *i.e.* $CO_2H.CH_2.CH(C_3H_5).CO_2H$.

[94°]. Plates (from alcohol). Prepared by heating allyl-ethane tri-carboxylic acid to 160°, CO_2 being evolved. Strong aqueous HBr converts it into the corresponding lactonic acid—

$$\begin{array}{l}CH_3.\underset{|}{CH}.CH_2.\underset{|}{CH}.CH_2.CO_2H\\ \quad\;\; O\text{———}CO\end{array}$$

Salts: $A''Ca^{\times}$: crystalline, soluble.—$A''Ba^{\times}$: easily soluble, amorphous.—$A''Ag_2{}^{\times}$: sparingly soluble, amorphous.—$FeSO_4$ gives a flocculent pp. (Hjelt, *B*. 16, 334).

ALLYL SULPHATE $C_3H_6SO_4$ *i.e.* $C_3H_5O.SO_2.OH$. *Hydrogen allyl sulphate. Allyl-sulphuric acid.* From allyl alcohol and H_2SO_4 (Cahours a. Hofmann, *C. J.* 10, 316).

Salts.—(Szymanski, *A*. 230, 43.) BaA'_2.—SrA'_2.—CaA'_2 2aq.—CuA'_2 4aq.—PbA'_2PbO 6aq.—MgA'_2 4aq.—KA'.—NaA'.—NH_4A'.

ALLYL SULPHIDE $C_6H_{10}S$ *i.e.* $(C_3H_5)_2S$. *Oil of Garlic.* M. w. 114. (140°).

Occurrence.—In the essential oils obtained by distilling, with steam, the leaves, seeds, or bulbs, of various plants (*allium sativum, alliaria officinalis, allium cepa, thlaspi arvense*). Often associated with allyl-thio-carbimide (*q.v.*) (Wertheim, *A*. 51, 289; 55, 297; Pless, *A*. 58, 36).

Formation.—From allyl iodide and alcoholic K_2S (Hofmann a. Cahours, *A*. 102, 291).

Properties.—A light oil, smelling of garlic.

Combinations.—1. Forms pps. with salts of Au, Hg, Pd, Pt, and Ag.—$(C_3H_5)_2SPtS_2$ (W.)—$(C_3H_5)_2SAgNO_3$ (Ludwig, *A*. 139, 121).

$HgS(HgCl_2)_32(C_3H_5)_2S$ (W.)

2. Combines with MeI (Cahours, *Z*. 1865, 438).

ALLYL SULPHOCYANIDE C_4H_5NS *i.e.* $C_3H_5.S.CN$. *Allyl thio-cyanate.* (161°). S.G. $^{\underline{0}}$ 1·071; $^{\underline{15}}$ 1·056.

Formation.—1. From lead salt of allyl mercaptan and cyanogen chloride in ethereal solution (Billeter, *B*. 8, 464):

$$(C_3H_5S)_2Pb + 2Cl(CN) = 2C_3H_5.S.CN + PbCl_2.$$

2. From ammonium sulphocyanide and a cold alcoholic solution of allyl bromide (Gerlich, *A*. 178, 85).

Properties.—Changes spontaneously into the isomeric allyl-thio-carbimide, especially when boiled. Alcoholic KOH forms KSCN. Does not give immediate pps. with ammoniacal $AgNO_3$ or alcoholic $HgCl_2$. Zn and HCl in alcohol form $(C_3H_5)_2S$ and HCN (G.). *Sodium amalgam* forms Na_2S and allyl carbamine (B.).

ALLYL-SULPHONIC ACID *v.* Propylene sulphonic acid.

ALLYL SULPHYDRATE *v.* Allyl mercaptan.

ALLYL-TAURINE $C_5H_{11}NSO_3$ *i.e.* $C_3H_5NH.CH_2.CH_2.SO_3H$. [190°-195°]. From $CH_2Cl.CH_2.SO_3H$ and allylamine at 160° (James, *C. J.* 47, 369). Prisms (from alcohol). V. e. sol. water.

ALLYL-THIO-CARBAMIC ACID *Ethyl ether* $C_6H_{11}NSO$ *i.e.* $C_3H_5NH.CS.OEt$. *Allyl-thio-urethane* (210°-215°). S.G. $^{\underline{14}}$ 1·036. From oil of mustard and alcohol at 110°:

$$C_3H_5N{:}CS + HOEt = C_3H_5NH.CS.OEt$$

(Hofmann, *B*. 2, 119). Ppd. by $HgCl_2Aq$.

Allyl-di-thio-carbamic acid $C_3H_5NH.CS.SH$. From allyl thio-carbimide and alkaline sulphydrates: $C_3H_5N{:}CS + HSK = C_3H_5NH.CS.SK$. The free acid is unstable.

Salts.—NH_4A' : unstable laminæ.—KA': large rhombic plates.—NaA' 3aq: unstable nacreous laminæ.—BaA'_2 4aq: laminæ; v. sol. water.—PbA'_2 : white pp. (Will, *A*. 52, 30).

ALLYL THIO-CARBIMIDE C_4H_5NS *i.e.* $C_3H_5N{:}CS$. *Oil of mustard, allyl mustard oil, allyl thio-cyanate, allyl iso-thio-cyanate, allyl sulphocyanide, allyl iso-sulpho-cyanide, allyl sulpho-carbimide.* M. w. 99. (151°). S.G. $^{\underline{0}}$ 1·028. S.V. 113·12 (R. Schiff, *B*. 19, 568). H.F.p. −45,540. H.F.v. −46,700. V.D. 3·54 (for 3·42).

Occurrence.—In the oil distilled from the seeds of black mustard (*sinapis nigra*). Also present in oil of garlic, and in horse-radish.

Formation.—1. Seeds of black mustard contain potassic myronate, and also an unorganised nitrogenous ferment, myrosin. When treated with water, the ferment splits up the potassic myronate thus:

$$C_{10}H_{18}NS_2O_{10}K = C_3H_5.NCS + C_6H_{12}O_6 + KHSO_4.$$

At low temperatures a little allyl sulphocyanide is also formed (E. Schmidt, *B*. 10, 187).—2. Allyl sulphocyanide (*q. v.*) changes, slowly at 15°, quickly on boiling, into allyl thio-carbimide. Consequently, when allyl iodide is distilled with alcoholic potassic sulphocyanide (Zinin, *A*. 95, 128; Berthelot a. De Luca, *A. Ch.* [3] 44, 495), or allyl sulphide (Wertheim, *A*. 55, 297), the product is allyl thio-carbimide.

Properties.—Oil with pungent odour and burning taste. Blisters the skin. Sl. sol. water, v. sol. alcohol or ether. Slowly decomposed by water, sulphur being liberated.

Reactions.—1. *Zinc and hydric chloride* reduce it to allylamine and thio-formic aldehyde: $C_3H_5NCS + 2H_2 = C_3H_5NH_2 + H_2CS$, the latter being partly reduced to methane and H_2S (Hofmann, *B*. 1, 179).—2. HClAq at 200° forms allylamine, CO_2, and H_2S (H.).—3. *Alcohol* at 100°, or *alcoholic potash*, forms allyl-thio-carbamic ether (*q. v.*).—4. *Aqueous alkalis*, or *water* and the oxides BaO, PbO, Ag_2O, or HgO, form di-allyl-urea: $2C_3H_5NCS + 3PbO + H_2O = (C_3H_5)_2N_2H_2CO + 2PbS + PbCO_3$.—5. K_2S at 100° forms potassic sulphocyanide and allyl-sulphide.—6. NH_3 forms allyl-thio-urea (*thio-sinamine*).—7. *Aldehyde-ammonia* forms needles of $C_{14}H_{31}N_5S_2O_2$ [108°] (R. Schiff *B*. 9, 571).—8. *Furfuramide* in alcoholic solution at

100° forms $C_{18}H_{12}N_2O_4C_3H_5NCS$ [118°] (R. Schiff, *B.* 10, 1191).—9. Boiling conc. $KHSO_3$ forms $C_3H_5NH.CS.SO_3K$. Pearly plates (form alcohol) (Böhler, *A.* 154, 59).

Combination.—$C_3H_5NCS\ Ag_2SO_4$. Formed by adding $AgNO_3Aq$ to aqueous potassic myronate (Will a. Körner, *A.* 125, 257).

Additional References.—Boutron a. Robiquet, *J. Ph.* 17, 296; Henry a. Plisson, *J. Ph.* 17, 451; Dumas a. Pelouze, *A. Ch.* [2] 53, 181; Aschoff, *J. pr.* 4, 314; Robiquet a. Bussy, *A. Ch.* [2] 72, 328; Boutron a. Fremy, *J. Ph.* 16, 112; Löwig a. Weidmann, *J. pr.* 19, 218; Will, *A.* 52, 1; Gerhardt, *A. Ch.* [3] 14, 125; Hubatka, *A.* 47, 153; Vollrath, *J.* 1871, 408; Grabowski, *A.* 138, 173.

ALLYL-THIO-HYDANTOIN $C_6H_8N_2SO$ *i.e.*

$$HN{:}C\begin{cases}N(C_3H_5){\cdot}CO\\ \quad\quad\quad\ \ |\\ S\text{———}CH_2\end{cases}$$

Formation.—(1) By the action of chloroacetic acid on allyl-thio-urea in aqueous solution at 100°. (2) By the action of allyl-cyanamide on thio-glycollic acid.

Minute needles. Sol. hot, sl. sol. cold, water.

The hydrochloride (B'HCl) forms glistening prisms. (Andreasch, *B.* 15, 326; *M.* 2, 775).

ALLYL-THIO-PARABANIC ACID *v.* THIO-PARABANIC ACID.

ALLYL-THIO-URAMIDO-BENZOIC ACID. $C_{11}H_{12}N_2SO_2$ *i.e.* $C_3H_5NH.CS.NH.C_6H_4.CO_2H$. [1:3] [189° uncor.]. Formed by boiling *m*-amido-benzoic acid with an alcoholic solution of allyl-thio-carbimide. Plates. (Aschan, *B.* 17, 431.)

ALLYL-THIO-UREA. $C_4H_8N_2S$ *i.e.* $C_3H_5NH.CS.NH_2$. *Thiosinamine.* M. w. 116. [74°].

Formation.—From allyl mustard oil and ammonia (Dumas a. Pelouze, *A. Ch.* [2] 53, 181; Aschoff, *J. pr.* 4, 314; Löwig a. Weidmann, *J. pr.* 19, 218; Robiquet a. Bussy, *J. pr.* 19, 232; Will, *A.* 52, 1).

Properties.—Prisms, without smell. M. sol. water, v. sol. alcohol, and ether.

Reactions.—1. HgO or PbO converts it into allyl-cyanamide (*q. v.*).—2. Warm $AgNO_3Aq$ forms allyl-urea.

Combinations. — $(C_4H_8N_2S\ HCl)_2PtCl_4$. — $C_4H_8N_2S2HgCl_2$: curdy white pp.—$C_4H_8N_2SAgNO_3$. —$C_4H_8N_2\ SBr_2$ [147°], six-sided columns; sol. water, and alcohol. Converted by moist Ag_2O into alkaline $C_4H_8N_2S\ BrOH$, whence HCl forms $C_4H_8N_2SBrCl$ [130°]. (Maly, *Z.* 1867, 42).— $(C_4H_8N_2SBr_2)_2PtCl_4$. — $(C_4H_8N_2SBrCl)_2PtCl_4$. — $C_4H_8N_2SBrClAuBr_3$. — $C_4H_8N_2SI_2$ [90°]. — $C_4H_8N_2SClI$.—$C_4H_8N_2SCy_2$: converted by hot dilute H_2SO_4 into allyl-THIO-PARABANIC ACID (*q. v.*). (Maly, *Z.* 1869, 259).—$C_4H_8N_2SICyAgCy$.

Ethyloiodide $C_4H_8N_2SEtI$. [72°] (Welzien, *A.* 94, 103; M.).

ALLYL-UREA $C_4H_8N_2O$ *i.e.* $C_3H_5NH.CO.NH_2$. *Allyl carbamide.* [85°]. *Formation.*—1. From allyl cyanate and hot NH_3Aq (Hofmann a. Cahours, *Tr.* 1857, 555).—2. From allylamine sulphate and potassic cyanate (Andreasch, *M.* 5, 34).—3. From allyl thio-urea and $AgNO_3Aq$, the liberated HNO_3 being neutralised by baryta. The yield is 92 p.c. of the theoretical.

Properties.—Needles. V. e. sol. water, and alcohol, v. sl. sol. $CHCl_3$, and ether. Br_2 forms di-bromo-propyl-urea.—Salt.—$B'HNO_3$.

Di-allyl-urea $(C_3H_5NH)_2CO$. *Sinapoline.* [100°].

Formation.—1. By action of water and PbO or baryta on allyl thio-carbimide (Simon, *P.* 50, 377; Will, *A.* 52, 25).—2. By heating allyl cyanate with water or aqueous potash.

Properties.—Unctuous shining laminæ. V. sol. alcohol, ether or hot water; volatile with steam. Its aqueous solution is ppd. by $HgCl_2$ and $PtCl_4$. Dry HCl liquefies sinapoline forming B'HCl.

ALMONDS.—Bitter almonds contain a glucoside, amygdalin (*q. v.*), and a nitrogenous unorganised ferment, emulsin. Sweet almonds contain amygdalin but not emulsin. When bitter almonds are ground up with cold water, the amygdalin is split up by emulsin:

$$C_{20}H_{27}NO_{11} + 2H_2O = C_7H_6O + CNH + 2C_6H_{12}O_6.$$

The *essential oil* of bitter almonds is obtained by distilling the product with steam. It contains benzoic aldehyde, prussic acid and mandelonitrile, the product of their union. The presence of mandelonitrile is indicated by the formation of phenyl-ethylamine when the oil is acted upon by nascent hydrogen (Fileti, *G.* 9, 416). Both sweet and bitter almonds yield by pressure a *fixed oil*, S.G. ^{15} ·913; this consists of oleïn with some stearin and palmitin. It is called *oil of almonds.*

ALNEÏN.—A golden yellow colouring matter in the alder, birch, and beech (Savigny a. Collineau, *C. C.* 1881, 703; *C. J.* 42, 309).

ALOES.—The thickened juice of various species of aloe.

ALOETIC ACID $C_{14}H_4N_4O_{10}$ aq, *i.e.* $C_{14}H_4(NO_2)_4O_2aq$(?). *Tetra-nitro-anthraquinone*(?) Obtained, together with chrysammic acid, by warming aloes with HNO_3 (Schunck, *A.* 39, 24; 65, 235; G. J. Mulder, *A.* 72, 286; Finck, *A.* 134, 236). Yellow amorphous powder. Sl. sol. cold water, m. sol. hot water or alcohol, forming purple solutions, which become yellow on addition of acids, and red again when neutralised. It has a bitter taste. Boiling HNO_3 converts it into chrysammic acid, and ultimately into picric acid. Warm *potassium* or *ammonium sulphide* containing excess of alkali forms an indigo-blue gelatinous mass. **Salts:** $BaC_{14}H_2N_4O_{10}$. Ag_2A'': insoluble, dark red powder.

ALOÏN.—The purgative principle in aloes. There are several varieties classified by Shenstone (*Ph.* [3] 13, 461) as follows: (1) *Nataloïns.*—Are not reddened by HNO_3, but converted by it into picric and oxalic acids.—(2) *Barbaloïns*—are reddened by HNO_3, aloetic, chrysammic, picric and oxalic acids being formed. These may be subdivided into (α)-*barbaloïns*, reddened by cold HNO_3 (S.G. 1·4), (β)-*barbaloïns*, reddened by fuming HNO_3, not by cold HNO_3 (S.G. 1·4). The aloïns may be extracted by hot water or hot spirit from the various aloes, and purified by re-crystallisation. They dissolve in caustic and carbonated alkalis, forming orange solutions. Their solutions are ppd. by lead subacetate.

(α)-**Barbaloïn,** $C_{16}H_{18}O_7$ and (β)-**Barbaloïn, Zanzaloïn** or **Socaloïn** $C_{16}H_{18}O_7$ occur in aloes from Barbadoes, Socotrina, Zanzibar and Jafferabad (T. a. H. Smith, *Chem. Gaz.* 1851, 107; Stenhouse, *P.M.* [3] 37, 481; Tilden, *C. J.* 25, 488; 28, 1270).

Reactions.—1. By distilling with *zinc dust* a very little methyl-anthracene may be got (

Schmidt, *B.* 8, 1275).—2. *Potash-fusion* gives orcin, *p*-oxybenzoic acid, and alorcinic acid.—3. Boiling *dilute sulphuric acid* forms *p*-coumaric acid.—4. HCl and $KClO_3$ form tri-chloro-aloïn, $C_{16}H_{15}Cl_3O_7$, yellow prisms (from alcohol).—5. *Bromine* forms tri-bromo-aloïn; yellow needles (from alcohol).—6. Ac_2O forms tri-acetyl-aloïn, $C_{16}H_{15}Ac_3O_7$: amorphous.

Nataloïn $C_{16}H_{18}O_7$ (?). Occurs in Cape aloes (Flückiger, *Ar. Ph.* [2] 149, 11; *Bl.* 17, 328; Tilden, *C. J.* 25, 153). Thin bright yellow scales; sl. sol. water, benzene, ether, CS_2, and $CHCl_3$. Its solution in H_2SO_4 is turned green by KNO_3, the colour changing through red to blue.

Additional References.—T. B. Groves, *Ph.* 16, 128; Orlowski, *Fr.* 5, 309; Hlasiwetz, *A.* 134, 287; Rembold, *A.* 138, 186; Bornträger, *Fr.* 20, 234; R. H. Groves, *Ph.* [3] 11, 1045; Lenz, *Fr.* 21, 220; Plenge, *Ph.* [3] 15, 330; Cripps a. Dymond, *Ph.* [3] 15, 633).

ALORCIC ACID $C_9H_{10}O_3$aq. [97°]. $C_9H_{10}O_3$ [115°] *i.e.* $C_6H_2(OH)Me_2.CO_2H$. Formed in small quantity, along with *p*-oxy-benzoic acid and orcin, by fusing aloes with KOH (Weselsky, *A.* 167, 65). Long needles. Sl. sol. cold water, v. sol. hot water, alcohol, and ether. The aqueous solution is not coloured by Fe_2Cl_6Aq, but alkaline solutions are turned cherry-red by air. *Hypochlorites* turn the aqueous solution of the acid purple-red, colour destroyed by excess. Basic, but not neutral, *lead acetate* gives a pp. Alorcic acid reduces *silver nitrate* and *Fehling's solution.* Fused with *potash* it forms orcin and K_2CO_3.

Salts. BaA'_2 6aq: small needles.—CaA'_2: needles—CuA'_2 4aq.

Acetyl derivative $C_9H_9AcO_3$: [125°]; needles.

Anhydride $C_9H_8O_2$: [138°]; formed by distilling the acid.

ALOXANTHIN $C_{15}H_{10}O_6$ *i.e.* $C_{14}H_3Me(OH)_4O_2$. From barbaloïn and socaloïn, but not from nataloïn, by chromic mixture. Reduced, by distillation with *zinc dust*, to methyl-anthracene. Its alkaline solutions are cherry-red. *Nitric acid* converts it into aloetic and chrysammic acids (Tilden, *Ph.* [3] 8, 231; *C. J.* 32, 903). It forms an acetyl derivative $C_{15}H_9AcO_6$.

ALPHA. To find compounds beginning with this prefix, remove the prefix and look for the remaining word.

ALPININ $C_{17}H_{12}O_6$. [174°]. Light yellow needles ($+H_2O$). Occurs, together with camphoride and galangin in the galanga-root (Jahns, *B.* 14, 2810).

ALSTONIDINE. [181°]. An alkaloid occurring along with alstonine (*q. v.*) and porphyrine (*q. v.*) in the bark of *Alstonia constricta.* It may be separated from porphyrine by its more sparing solubility in petroleum. It crystallises in radiating needles, sol. alcohol, chloroform, and ether. Its solutions display intense blue fluorescence. It is not coloured by conc. H_2SO_4 or HNO_3. Its salts crystallise in colourless needles. The gold and platinum salts are golden flocculent pps. (Hesse, *A.* 205, 368).

ALSTONINE $C_{21}H_{20}N_2O_4$ 3½aq. *Chlorogenine* (F. v. Müller a. L. Rummel, *C. J.* 35, 31; Oberlin a. Schlagdenhauffen, *Ph.* [3] 10, 1059; O. Hesse, *A.* 205, 360). An alkaloid in the bark of *Alstonia constricta* (F. v. M.), from which it may be extracted by alcohol. The extract is evaporated, treated with very dilute HCl, filtered, ppd. by NH_3, dissolved in ether and evaporated.

Properties.—Orange-yellow, brittle, pellucid, bitter, mass. It melts below 100°. When dry, it melts at 195°. It dissolves easily in alcohol, ether, chloroform, and dilute acids, but sparingly in water. All dilute solutions show blue fluorescence. Salts. Ppd. by excess of acid.—$(B'HCl)_2PtCl_4$ 4aq.—$(B'HCl)_2HgCl_2$.—$B'_2H_2Cr_2O_7$.

ALUMINA.—Oxide of Aluminium, Al_2O_3, *v.* Aluminium, Oxide of.

ALUMINATES.—Certain minerals are known, *e.g.* Al_2O_3MgO, Al_2O_3BeO, &c., which may be regarded as derived from the hydrate $Al_2O_3.H_2O$ (*v.* Aluminium, Hydroxides of), by replacing H_2 by Mg, Be, &c. Some of these minerals have been prepared by Ebelmen (*A. Ch.* [3] 22, 211) by dissolving Al_2O_3 and the other metallic oxide in molten boric acid, and removing part of the solvent by long-continued heating; in this way he prepared spinelle Al_2O_4Mg, chrysoberyl Al_2O_4Be, &c. By heating Al_2F_6 with boric acid and ZnF_2, Deville and Caron obtained gahnite Al_2O_4Zn.

Barium aluminate $Al_2O_4Ba.4H_2O$ was obtained in crystals by fusing Al_2O_3 and carbon with BaO, $BaCO_3$, $Ba2NO_3$, or $BaSO_4$, dissolving in water and crystallising (Deville, *C. R.* 54, 327; *v.* also Gaudin, *C. R.* 54, 687; also Beckmann, *J. pr.* [2] 26, 388 a. 474). Compounds of Al_2O_3 and BaO obtained by action of BaOAq on Al_2O_3 and Al_2Cl_6Aq are described by Beckmann (*B.* 14, 2151).

Potassium aluminate $Al_2O_4K_2.3H_2O$ was obtained in crystals by Fremy (*A. Ch.* [3] 12, 362) by fusing Al_2O_3 and KOH in a silver dish, dissolving in water, and evaporating *in vacuo*; this salt may be recrystallised from *con.* aqueous solutions, from dilute solutions $Al_2O_6H_6$ separates out.

Sodium aluminate has not been obtained crystallised. An impure salt is used in manufactures; it is obtained by heating cryolite and CaO, or bauxite and NaOH, in steam, dissolving in water and evaporating to dryness (Morin, *J.* 1862. 668). Tissier (*C. R.* 48, 627) described four compounds to which he assigned the compositions $Al_2O_6Na_6$, $Al_4O_9Na_6$, $Al_2O_5Na_4$, and $Al_2O_4Na_2$; but no analyses are given in the original paper. M. M. P. M.

ALUMINIUM.—Al. At w. 27·02 (Mallet, *T.* 171, 1003). Mol. w. unknown as V.D. has not been determined. [About 700°]. S.G. $\frac{4°}{4}$ (fused) 2·583 (Mallet, *T.* 171, 1003); (after pressure of 6,000 atmos.) 2·562 (Spring, *A. Ch.* [5] 22, 170). S.H. ·218 (Louguinine, *A. Ch.* [5] 27, 398); (0°–100°) ·2253 (Mallet, *l.c.*). C.E. (lin. at 40°) ·002313; (lin. 50°) ·002336 (Fizeau, *C. R.* 68, 1125) T.C. (Ag = 100) 31·33 (Lorenz, *W.* 13, 422). E.C. (Hg at 0° = 1) 20·97 at 0°, 16·15 at 15° (Lorenz, *l.c.*). S.V.S. 10·4. Chief lines in spectrum, 3960·9, 3943·4, 3612·4, 3091·9, 3081·2, 2815·3, 2630·6 (Hartley, *T.* 175, 101).

Occurrence.—The metal aluminium does not occur native; but as silicate (in all clays and in very many minerals, especially the felspars), and oxide (corundum, diaspore, &c.), and fluoride (cryolite), it is very widely and largely distributed, forming nearly $\frac{1}{12}$ of the earth's crust. Alumina was shown to be a distinct earth by Marggraff in 1754; the metal was separated by Wöhler in

1328 (*P.* 11, 146), and in purer form in 1854 (*A.* 53, 422).

Preparation.—Wöhler decomposed Al_2Cl_6 by K; in 1854 Deville employed Na and decomposed $2NaCl.Al_2Cl_6$ (*J. pr.* 61, 83, 113, 219, 386). Bunsen (*P.* 92, 648) decomposed fused $2NaCl.Al_2Cl_6$ by an electric current. Rose (*P.* 96, 152) decomposed $6NaF.Al_2F_6$ (cryolite) by fusing it with KCl and Na. Basset (*J.* 1869. 753) reduced $2NaCl.Al_2Cl_6$ by Zn, and heated the Zn-Al alloy to white heat to remove the Zn. The Al_2Cl_6 may also be reduced by KCN (Wagn, *J.* 1858. 1); a compound of Al and S may be reduced by Fe, or by hydrocarbons (Petitjean, *J.* 1858. 136); and in other ways. The usual method of preparation is to heat $2NaCl.Al_2Cl_6$ with about 36 p.c. Na and 40 p.c. cryolite (as a flux), on the hearth of a reverberatory furnace, and to run off the molten Al into iron moulds. The $2NaCl.Al_2Cl_6$ is prepared by heating bauxite (silicate of Al containing Fe) with Na_2CO_3, whereby Na aluminate is formed, dissolving in water, ppg. Al_2O_3 by a stream of CO_2, collecting, washing, and drying the Al_2O_3, mixing it with charcoal and NaCl and heating strongly in Cl whereby $2NaCl.Al_2Cl_6$ is formed and distilled off into receivers. Mallet (*T.* 171, 1003), prepared very pure Al by fusing Al_2Br_6 with KCl and NaCl in the ratio $2(KCl.NaCl):Al_2Br_6$, and then heating with Na in clay crucibles lined with Al_2O_3 and Na aluminate; the reduced metal was heated on a support of Al_2O_3, washed with HClAq, then with water, and dried at a gentle heat.

Properties.—A tin-white metal; grey when in powder. Odourless and tasteless. After fusion about as hard as silver; hammered metal is about as hard as soft iron. Very malleable, and ductile; very sonorous; may be highly polished. Tenacity nearly equal to that of Cu (V. Burg, *D.P.J.* 151, 286); less than that of Zn (Karmarsch, *D.P.J.* 152, 441; 172, 55). Very feebly magnetic. Melts fairly easily (about 700°) and crystallises, apparently in regular octahedra, on cooling. Non-volatile, and non-oxidisable in air; heated in oxygen becomes covered with film of Al_2O_3. Unacted on by H_2S or ammonium sulphides, and by S only at high temperatures. Scarcely attacked by HNO_3Aq, but dissolved by HClAq, H_2SO_4Aq, KOHAq, and NaOHAq. Most specimens of Al contain Fe and Si; they are more easily oxidised than the pure metal.

Aluminium forms one series of salts the simplest formulæ of which represent them as derived from acids by replacement of H_3 by Al; *e.g.* $Al_2.3SO_4$, $Al3NO_3$ &c.

The atom of Al is trivalent in the gaseous molecule $AlCl_3$. Many experiments have been conducted to determine the mol. w. of Al chloride; Nilson a. Pettersson have finally shown (*Z. P. C.* 4, 206) that the only molecules which exist throughout a considerable range of temperature have the composition $AlCl_3$. Odling (*P. M.* [4] 29, 316) stated the V.D. of Al methide to be 36·2 at temperatures above 200° (and 72·4 at 130°); and hence mol. w. $Al(CH_3)_3$. It remained, however, uncertain whether the gas was homogeneous or not (*v.* Wanklyn, *P. M.* [4] 29, 313; Williamson, *ibid.* 395; Le Roux a. Louïse, *C. R.* 106, 73). Quincke (*Z. P. C.* 3, 164) has shown that the molecular formula of Al methide is $Al(CH_3)_3$.

The atomic weight of Al has been determined; (i.) by analyses and determination of V.D. of Al_2Cl_6, Al_2Br_6, and Al_2I_6; (ii.) by measurements of S.H. of Al; (iii.) by comparison of various compounds (*e.g.* Al_2O_3, and alum) with isomorphous compounds of Cr and Fe; (iv.) by analyses of ammonia-alum and Al_2Br_6, and by measuring the H evolved by the action of Al on NaOHAq (Mallet, *T.* 171, 1003 i.; *v.* also for older determinations Berzelius, *P.* 8, 187; Dumas, *A.Ch.* [3] 55, 151; Tissier, *C.R.* 46, 1105; Terreill, *Bl.* 31, 153).

Aluminium is a distinctly metallic element; no allotropic forms of it are known. According to the investigations of Wheatstone (*J.* 1855. 22), in KOHAq Al is electropositive to Cd, Sn, Pb, Fe, Cu, and Pt, and negative to Zn; in HClAq Al is positive to Sn and Pb, and negative to Zn and Cd. Al decomposes H_2O at 100°. It reacts with acids to form definite salts, but at the same time hydrated Al_2O_3 dissolves in alkalis to form unstable salts in which the Al forms a part of the negative, or acid, radicle (*v.* ALUMINATES).

The thermal value of the action of acids on $Al_2O_3.3H_2O$ is a large positive number approximately equal to the value for CdO_2H_2 and FeO_2H_2, although considerably less than the values of the corresponding actions with CaO_2H_2, SrO_2H_2, and BaO_2H_2 thus (Thomsen):—

M	(M, 2HCl Aq]	M	[M, 2HCl Aq.]
CaO_2H_2	30,490	$\frac{Al_2O_6H_6}{3}$	18,640
SrO_2H_2	27,630	CdO_2H_2	20,290
BaO_2H_2	40,012	FeO_2H_2	21,390

The difference between the heat of formation of a metallic chloride and hydroxide has usually a positive value; in the case of a non-metallic chloride and oxide the difference is usually a negative quantity (Thomsen, *Th.* 3, 531); in the case of Al the difference in question has a large negative value, thus $[Al^2, Cl^6] - [Al^2, O^3, 3H^2O] = -22,320$. Al shows several analogies with Be; they both very readily form basic and double salts; Al_2O_3 is less basic than BeO; both metals readily alloy with Si; neither seems to be easily acted on by S. For fuller discussion of the chemical relations of Al *v.* EARTHS, METALS OF THE.

Reactions.—1. Pure Al is unacted on by *ordinary air;* impure specimens of the metal become covered with a film of oxide.—2. *Water* is decomposed by Al at 100° with evolution of H.—3. *Con.* or dilute *nitric acid* has no action on Al.—4. The metal is easily dissolved by *hydrochloric acid.*—5. Dilute *sulphuric acid* evolves H, forming $Al_2.3SO_4$; hot *con.* H_2SO_4 evolves SO_2.—6. Most *carbon acids*, *e.g.* acetic, tartaric, have little or no action on Al; but in presence of NaClAq the action becomes marked, Al_2Cl_6 being formed.—7. *Sulphuretted hydrogen* has no action even at high temperatures.—8 *Aqueous potash or soda* dissolves Al, evolving H, and forming an aluminate (*v.* Cavazzi, *G.* 15, 202); molten KOH or NaOH does not act on Al.—9. *Sulphates, carbonates, borates, and silicates, of the alkali metals* are decomposed by Al at high temperatures.—10. *Potassium nitrate* oxidises Al when the two react at a white heat. 11. *Alkali sulphides* are without action even at high temperatures; *silver sulphide* when heated with Al is partly reduced with formation of a Ag-Al alloy.—12. Many *metallic oxides* are deoxidised by Al at high temperatures, *e.g.* oxides of Pb, Cu, Fe; oxides of Zn and Mn are not acted on.—13. *Alkaline*, but not neutral or slightly acid, *solutions of lead, silver, and tin*, are reduced by Al with ppn. of the metals; Cu is ppd. from $CuSO_4Aq$.—14. Most *metallic chlorides* in solution are reduced by Al (KClAq, NaClAq are exceptions; Cossa, *Z.* [2] 6, 380, 443). Fused zinc chloride, but not $MgCl_2$, is reduced by Al (Flavitsky, *B.* 6, 195).

Combinations.—1. With *oxygen* to form Al_2O_3; only at high temperatures, and then superficially.—2. With *sulphur* to form an unstable compound (*v.* ALUMINIUM, SULPHIDE OF) only at very high temperatures.—3. Wöhler (*P.* 11, 160) states that Al combines with *phosphorus, selenion, tellurium, and arsenic*, when heated in the vapours of these elements; but little is known of the compounds.—4. With *boron* Al forms at least two compounds (*v.* ALUMINIUM, BORIDES OF).—5. With *chlorine, bromine*, and *iodine*, Al combines to form Al_2Cl_6, Al_2Br_6, and Al_2I_6 (*q. v.*).—6. Al forms *alloys* with most of the metals; these alloys are usually formed by heating the metals together; or sometimes by heating Al_2O_3 and carbon with the other metal. The properties of many metals are considerably changed by alloying with small quantities of Al. The alloys of Al with Cu, Ag, and Sn are much used because of their colour, hardness, and stability, and the ease with which they are worked. The alloys of Al have been chiefly studied by Calvert a. Johnson (*P. M.* [4] 10, 240); Tissier (*C. R.* 43, 885; 49, 54); Debray (*C. R.* 44, 925); Wöhler (*A.* 106, 118; 113, 248; 138, 253; *P.* 11, 161); Michel (*A.* 115, 102). The alloys with *copper* containing from 6 to 10 per cent. Al are yellow, hard, unacted on by moist air, water, or salt solutions, and are easily worked. The alloys with *silver* are also very stable, have a fine colour and may be highly polished. When a little Al is alloyed with *tin* the products are very hard and elastic. (These alloys will be more fully described under COPPER, SILVER, and TIN.) Alloys of Al with the following metals have been prepared:—Bi (a very little Bi makes Al extremely brittle); Ca (by heating Al, Na, and much $CaCl_2$, Wöhler); Cu, Cr (by heating Al with $Cr_2Cl_6.KCl$, Wöhler); Au, Fe, Mg, Mn (by heating $MnCl_2$, KCl, NaCl, and Al); Hg (Cailletet, *C. R.* 44, 1250); Mo, Ni, Pt, Ag, Na (this alloy easily decomposes H_2O); Sn, Ti, W (by heating WO_3 with Al, cryolite, and KCl, and NaCl); and Zn.

Detection.—Many Al compounds are soluble in water; most are dissolved by HClAq. Strongly heated Al_2O_3 is nearly insoluble in acids; it, and also the insoluble Al-containing minerals, may be dissolved by fusion with $KHSO_4$ and treatment with water (H. Rose, *P.* 1, 275).

Estimation.—1. Usually as Al_2O_3: a fairly *con.* solution is ppd. by a small excess of NH_3Aq (if Mg salts are present a good deal of NH_4ClAq is added), the free NH_3 is removed by warming, the pp. is washed, thoroughly dried, and strongly heated for some time.—2. $Al_2O_6H_6$ may also be ppd. by $Na_2S_2O_3Aq$. This method is specially applicable in presence of Fe salts; the two metals are ppd. as hydrates, the pp. is dissolved in HClAq, the solution is nearly neutralised by Na_2CO_3Aq and diluted so that 50 c.c. do not contain more than ·1 gram Al_2O_3 a slight excess of $Na_2S_2O_3Aq$ is added, and after a little the liquid is boiled so long as SO_2 comes off, the pp. of $Al_2O_6H_6$ mixed with S is filtered hot, washed with hot water, and strongly heated until all S is burnt off; ($Al_2Cl_6Aq + 3Na_2S_2O_3Aq + 3H_2O = Al_2O_6H_6 + 6NaClAq + 3S + 3SO_2$; $Fe_2Cl_6Aq + 2Na_2S_2O_3Aq = Fe_2Cl_4Aq + 2NaClAq + Na_2S_4O_6Aq$) (*v.* Chancel, *C. R.* 46, 987).—3. Al is also sometimes estimated as a basic acetate (*v.* Atkinson, *Fr.* 3, 329; also Schulze, *J. pr.* 47, 313); or as basic formate (Schulze, *C. C.* 1861, 3). For methods of separating Al from alkaline earths *v.* Deville, *A. Ch.* [3] 38, 5; from Co, Ni, and Zn *v.* Haidlen a. Fresenius, *A.* 43, 129; from iron *v.* Macivor, *C. N.* 29, 199; from iron and phosphoric acid *v.* Flight, *C. J.* [2] 13, 592; also Esilman, *C. N.* 28, 208; from chromium *v.* Dexter, *P.* 89,142.

Aluminium, Alloys of, *v.* ALUMINIUM; *Combinations*, No. 6.

Aluminium, Arsenide of. According to Wöhler (*P.* 11, 160) Al combines with As when the elements are heated together; the product is a grey metal-like mass, decomposed by water with evolution of AsH_3. No analyses are given.

Aluminium, Borides of. Al seems to form two definite compounds with boron, AlB_2 and AlB_{12}. They may be obtained by packing a rod of Al in amorphous B in a carbon crucible, placing this in a Hessian crucible with powdered charcoal between the crucibles, covering, and heating to redness for 1½ or 2 hours; B_2O_3 may be used in place of B (10 parts B_2O_3 to 8 parts Al). On cooling, the fused mass is treated with HClAq, whereby Al dissolves and crystals of the borides remain, which may be separated by hand (Hampe, *A.* 183, 75). Both borides were obtained by Wöhler and Deville and regarded by them as crystallised boron (*A.* 101, 113, and 347; 141, 268); the compositions represented by the formulæ AlB_2 and AlB_{12} are assigned by Hampe (*l. c.*). AlB_2 crystallises in thin, lustrous, pale copper-coloured, six sided, plates; unchanged by heating in air; slowly dissolved by hot *con.* HClAq and NaOHAq, easily soluble in warm HNO_3Aq. This compound may be prepared by the action of BCl_3 vapour on hot Al; or by heating $BF_3.KF$ with KCl, NaCl, and Al. AlB_{12} forms black, monoclinic crystals, transparent in very thin plates; harder than corundum, softer than diamond S.G. = 2·534. These crystals are unacted on by *con.* HClAq or KOHAq, and very slowly by hot *con.* H_2SO_4Aq; they are soluble in hot *con.* HNO_3Aq. They are oxidised by molten KOH and $PbCrO_4$; also by molten $KHSO_4$; but are not acted on by molten KNO_3. Heated with Pt an easily fusible alloy is formed.

Aluminium, Borocarbide of. $Al_3C_2B_{48}$. Originally obtained by Wöhler and Deville, and supposed to be crystallised boron; examined more fully by Hampe (*A.* 183, 90). Prepared by long-continued heating at a very high temperature of B_2O_3 and Al in a graphite crucible (for details, *v.* Hampe, *l.c.*). The compound crystallises in yellowish, sparkling, crystals of the dimetric system. S.G. = 2·615; hardness between that of diamond and corundum. The crystals

are slowly dissolved by hot *con.* HNO_3Aq, but not by $HClAq$, H_2SO_4Aq, or $KOHAq$; they behave towards molten KOH, $PbCrO_4$, and $KHSO_4$ similarly to AlB_{12} (*q.v.*).

Aluminium, Bromide of. $AlBr_3$ or Al_2Br_6; **not certain.** [abt. 90°] (Weber, *P.* 103, 251). (263°·3) at 747 mm. (Mallet, *T.* 1880. 1003). S.G. 2·54. V.D. 266·8 (Deville a. Troost, *A. Ch.* [3] 58, 257). H.F. $[Al^2,Br^6]$ = 239,440 (*Th.* 3, 240).

Formation.—By passing Br vapour over a heated mixture of alumina and charcoal.

Preparation.—By the action of Br on excess of powdered Al, and subsequent repeated distillation from Al, and finally in atmosphere of N. (Mallet, *l.c.*)

Properties.—White, lustrous, plates; fumes in air; melts to a mobile liquid; soluble in CS_2, alcohol, and water, in latter with production of much heat $[Al^2Br^6, Aq]$ = 170, 600 (*Th.* 3, 240).

Reactions and Combinations.—Aqueous solution on evaporation *in vacuo* yields crystals of Al_2Br_6, $12H_2O$; this solution is decomposed on heating into $Al_2O_6H_6$ and HBr. Al_2Br_6 is decomposed into Al_2O_3 and HBr when heated in air; it combines with the bromides of the alkali metals to form double salts, *e.g.* $2KBr.Al_2Br_6$ (Weber, *P.* 103, 259); it absorbs NH_3, also H_2S, forming compounds which are decomposed by heat (Weber, *l.c.*).

Aluminium, Chloride of. $AlCl_3$. Mol. w. 133·13 (800°–1500°) (Nilson a. Pettersson, *Z. P. C.* 4, 206). V.D. 66·5 (N. a. P. *l.c.*). H.F. $[Al,Cl^3]$ = 160, 980 (*Th.* 3, 240).

Formation.—1. By heating powdered Al to redness in dry Cl.—2. By passing HCl mixed with CS_2 vapour over crude alumina or clay heated to redness; Al_2S_3 is formed but is at once decomposed by the HCl (Curie, *C. N.* 28, 307).—3. By heating Al with various metallic chlorides, *e.g.* $ZnCl_2$ (Flavitsky, *B.* 6, 195).—4. By heating Al_2O_3 with NH_4Cl (Rose, *P.* 74, 569), or with PCl_5, BCl_3, or $SiCl_4$ (Troost a. Hautefeuille, *C. R.* 75, 1710 and 1819).

Preparation.—100 parts Al_2O_3 are made into a thick paste with 40 parts carbon by the help of starch paste, or oil; the paste is kneaded to a cylinder, which is dried, heated in a covered crucible, and removed while hot to a porcelain tube connected with a Cl apparatus; as soon as the apparatus is full of Cl, the cylinder is heated to redness; Al_2Cl_6 distils over into a receiver. It is purified by sublimation from Al in a closed tube bent to an obtuse angle.

Properties.—Transparent, deliquescent, hexagonal plates; colourless when pure, but usually yellowish because of presence of chlorides of Fe, S, &c. Fusible in large masses but volatilises without fusion if heated in small quantities. Soluble in water with production of much heat $[Al^2Cl^6,Aq]$ = 153,690 (*Th.* 3, 240); soluble in alcohol, and ether; insoluble in benzene; unacted on by HClAq.

Reactions.—1. Fumes in *moist air* absorbing H_2O and giving off HCl.—2. Easily decomposed (to Al_2O_3 and HCl) by *steam* (Kuhnheim, *J.* 1861. 149).—3. Partly decomposed by *oxygen* at a red heat with evolution of Cl (Berthelot, *C. R.* 86, 787).—4. Heated to redness with *lime*, corundum (Al_2O_3) is formed; with *magnesia*, spinelle (Al_2O_4Mg) is produced (Daubree, *C. R.* 39, 135).—5. **Decomposed below red heat by *potassium or sodium*, with production of Al, and KCl, or NaCl.—6. Molten Al_2Cl_6 is *electrolysed* to Al and Cl (Buff, *A.* 110, 257).—7. *Sulphuric anhydride* forms $Al_2.3SO_4$, SO_2, and Cl.—8. *Solution in water* is decomposed by *heat* into Al_2O_3 and HCl.**

Combinations.—1. Dissolves in *water*; solution when slowly evaporated gives deliquescent crystals of $Al_2Cl_6.12H_2O$ (Bonsdorff, *P.* 27, 279).—2. Absorbs dry *ammonia* to form yellow $Al_2Cl_6.6NH_3$; when this is heated in a stream of dry H, $Al_2Cl_6.2NH_3$ is obtained (Persoz, *A. Ch.* 44, 319).—3. Combines with *phosphoretted hydrogen* to form a yellow powder $3Al_2Cl_6.2PH_3$, decomposed by H_2O giving off PH_3 (Rose, *P.* 24, 295).—4. *Phosphoric chloride* at 180° forms $Al_2Cl_6.2PCl_5$; crystalline, easily fusible, easily decomposed by H_2O (Weber, *P.* 107, 375).—5. Combines with some other *non-metallic chlorides*; chief combinations are $Al_2Cl_6.2POCl_3$ (Casselmann, *A.* 98, 220); $Al_2Cl_6.2NaCl$ (Weber, *P.* 118, 471); $Al_2Cl_6.SCl_4$, $Al_2Cl_6.SeCl_4$, and $Al_2Cl_6.TeCl_4$ (Weber, *P.* 104, 421). Forms a compound with H_2S which is decomposed by H_2O (Wöhler, *P.* 11, 160).—6. Combines with *chlorides of alkali metals* to form $Al_2Cl_6.2MCl$ (Degen, *A.* 18, 332; Deville, *A. Ch.* [3] 43, 30); the most important is $Al_2Cl_6.2NaCl$, white crystals, melting at about 185°, volatile at a red heat without decomposition; deliquescent, but much less so than Al_2Cl_6. This salt is prepared on the large scale, as from it the metal Al is obtained (*v.* ALUMINIUM, *Preparation of*).—7. By evaporating solutions of the mixed chlorides the compounds $Al_2Cl_6.2PdCl_2.20H_2O$ and $Al_2Cl_6.2PtCl_4.30H_2O$ were obtained (Welkow, *B.* 7, 304 and 802).—8. With *sulphurous anhydride* forms $Al_2Cl_6.2SO_2$, a heavy liquid, solidifying at −10° (Andrianowsky, *Bl.* [2] 31, 495).

Aluminium, Fluoride of. AlF_3. Mol. w. uncertain, as V.D. not determined. S.G. 3·1.

Occurrence.—In combination with NaF as *cryolite* $Al_2F_6.6NaF$; also with silicates in topaz, &c.

Formation.—1. By action of HF on Al_2O_3.—2. By fusing cryolite with $Al_2.3SO_4$, and digesting in water whereby Na_2SO_4 is dissolved and Al_2F_6 remains (Deville, *C. R.* 42, 49).

Preparation.—A mixture of fluorspar and alumina, in a boat of graphite, is heated to fusion in a tube of graphite, in dry HCl; crystals of Al_2F_6 sublime and $CaCl_2$ remains (Deville, *C. R.* 43, 971).

Properties and Reactions.—White, and very obtuse rhombohedra; unacted on by air, by acids, or by aqueous alkalis (Deville, *C. R.* 43, 970). Volatile at bright red heat.

Combinations.—1. With *hydrofluoric acid* and *water*: by dissolving Al_2O_3 in H_2SiF_6Aq, digesting with Al_2O_3 till SiO_2 is ppd. and solution is neutral, and evaporating, crystals of $Al_2F_6.7H_2O$ are obtained; if digestion with Al_2O_3 is stopped while liquid is distinctly acid but SiO_2 is ppd., and alcohol is added, $3Al_2F_6.4HF.10H_2O$ is formed; if, instead of adding alcohol, the acid liquid is evaporated $Al_2F_6.HF.5H_2O$ is produced (Deville, *A. Ch.* [3] 61, 327).—2. With *alkali fluorides* compounds of the form $Al_2F_6.6MF$ are formed, the most important of these are the K and the Na compounds. $Al_2F_6.6KF$ is obtained as a gelatinous pp. by adding a solution of Al_2O_3 in HFAq to an excess of KFAq. Al_2F_6.

4KF is produced by adding KFAq to excess of Al_2F_6 in HFAq; if the pp. is boiled in the liquid $Al_2F_6.6KF$ is formed. Both pps. form white powders when dry, and are decomposed with loss of all their F by heating with *con.* H_2SO_4Aq. $Al_2F_6.6NaF$ occurs native as cryolite on the west coast of Greenland. S.G. = 2·96. It may be prepared by the action of HFAq on Al_2O_3 and Na_2CO_3, mixed in ratio $Al_2O_3:3Na_2CO_3$, drying, and heating to fusion. Forms colourless, transparent, dimetric crystals; softer than felspar; melts below red heat, forming a colourless glass on cooling. Decomposed to CaF_2 and a solution of Al_2O_3 in NaOHAq, by boiling with milk of lime, or fusing with $CaCO_3$ and boiling in H_2O. Heated with H_2SO_4Aq loses HF, and produces $Al_2.3SO_4$ and Na_2SO_4.

Aluminium, Hydrated Oxide of, *v.* ALUMINIUM, HYDROXIDES OF.

Aluminium, Hydroxides of. Three compounds of Al, H, and O are known; they react rather as hydrated oxides, $Al_2O_3.xH_2O$ where $x = 1$, 2, and 3, than as hydroxides. Al_2O_3 which has not been strongly heated takes up H_2O; but the definite compounds are obtained by indirect methods; Al_2O_3 which has been strongly heated has no action on H_2O. The hydrates of Al_2O_3 lose their water at a red heat. When freshly ppd. they dissolve easily in acids, forming the same salts Al_2X_6 where X = acid radicle (*v.* ALUMINIUM, SALTS OF). Thomsen gives the following thermal values $[Al^2,O^3,3H^2O] = 388{,}920$; $[Al, O^3, H^3] = 297{,}000$; $\left[\frac{Al^2O^6H^6}{3}, H^2SO^4Aq\right] = 20{,}990$; $\left[\frac{Al^2O^6H^6}{3}, 2HClAq\right] = 18{,}640$ (*Th.* 3, 240). The hydrates also dissolve in KOHAq and NaOHAq with formation of easily decomposed aluminates (*q. v.*). The hydrates, especially $Al_2O_3.3H_2O$, form a class of bodies called *lakes* by their action on vegetable colouring matters; they pp. these colouring matters from solutions, hence these hydrates are used as *mordants*.

I. MONOHYDRATE. $Al_2O_3.H_2O$ ($= Al_2O_4H_2$). Occurs native as *diaspore*, in transparent, trimetric crystals, S.G. 3·43, which crumble to powder when heated but lose all H_2O only at about 360°; insoluble in water and in boiling HClAq. By heating amorphous Al_2O_3 in a closed tube with H_2O to 240°–250° Mitscherlich obtained hydrated Al_2O_3 nearly agreeing in composition with formula $Al_2O_3.H_2O$ (*J. pr.* 83, 468). According to Becquerel (*J.* 1868. 87; *J.* 1874. 132) crystalline $Al_2O_3.H_2O$ is produced when a tube containing Cr_2Cl_6Aq and covered with parchment paper is suspended in a solution of Al_2O_3 in KOHAq.

II. DIHYDRATE. $Al_2O_3.2H_2O$ ($= Al_2O_5H_4$). Occurs native as amorphous *bauxite* (Berthier, *S.* 35, 154). Prepared by the action of NH_4ClAq on Al_2O_3 in KOHAq, washing, and drying at 100° (Löwe, *Z.* 3, 247); also by ppg. hot solutions of Al salts by NH_3Aq, digesting the pp. in the warm liquid, washing, and drying at 100° (St. Gilles, *A. Ch.* [3] 46, 58). A dihydrate is also obtained by the slow decomposition of basic aluminium acetate, and subsequent evaporation to dryness at 100° (*v.i.*). The dihydrate is said to be nearly insoluble in acids and aqueous alkalis. Two varieties of $Al_2O_3.2H_2O$ in aqueous solutions were obtained by Crum (*C. J.* 6, 225), and Graham (*T.* 1861. 183), respectively. Crum prepared basic Al acetate

$$(2Al_2(C_2H_3O_2)_6.Al_2O_6H_6.3H_2O),$$

dissolved this by heating with much water, heated this solution to 100° in a closed tube for ten days, whereby the salt was decomposed into acetic acid and $Al_2O_3.xH_2O$, then diluted, and boiled in an open vessel until all acetic acid was removed. The solution of $Al_2O_3.xH_2O$ thus obtained was colourless, tasteless, and neutral to litmus; it was easily coagulated by small quantities of sulphuric, citric, tartaric, and many other acids, and by various salts, not by acetic, formic, boric, and one or two other acids. This solution does not act as a mordant; evaporated at 100° $Al_2O_3.2H_2O$ insoluble in acids is oobtined; the coagulated hydrate dissolves in *con.* acids. Graham dissolved $Al_2O_3.xH_2O$ in Al_2Cl_6Aq or in Al acetate solution, and dialysed; the aqueous solution of $Al_2O_3.xH_2O$ thus obtained was very easily coagulated by acids, alkalis, and salts; it acted as a mordant; the coagulated hydrate dissolved easily in dilute acids.

III. TRIHYDRATE. $Al_2O_3.3H_2O$ ($= Al_2O_6H_6$). Occurs native, in hexagonal, fibrous, crystals, as *gibbsite*, and *hydrargyllite*. Prepared by ppg. cold solution of Al salts by NH_3Aq, or $(NH_4)_2CO_3Aq$, washing, dissolving in HClAq, reppg., washing, and drying at 100°. A soft, friable, white powder; easily soluble in acids and fixed aqueous alkalis; insoluble in water. When freshly ppd. it forms a gelatinous mass, soluble to some extent in NH_3Aq, but reppd. on standing in air. Heated to redness it loses all its H_2O, and contracts considerably. A crystalline trihydrate is formed by the action of air on a saturated solution of Al_2O_3 in KOHAq (Bonsdorff, *P.* 27, 275); it is insoluble in cold acids, slowly dissolved by boiling HClAq, more rapidly by H_2SO_4Aq. $Al_2O_3.3H_2O$ is also said to be formed by the action of H_2O on Al amalgam (Cossa, *Z.* 13, 443).

Aluminium, Iodide of. AlI_3 or Al_2I_6; not certain. [abt. 185°] (abt. 360°) (Weber, *P.* 101, 465; 103, 259). S.G. 2·63. V.D. 387·4 (Deville a. Troost, *A. Ch.* [3] 58, 257). H.F. $[Al^2,I^6] = 140{,}780$ (*Th.* 3, 240).

Preparation.—Al in small pieces is placed in a retort, about ½ to 1 p.c. of the calculated quantity of I is added, CO_2 is led in, and the retort is heated until combination occurs; rather less than the quantity of I needed to convert all the Al into Al_2I_6 is then added, and heating, in a steam of CO_2, is continued until Al_2I_6 sublimes (Gustavson, *A.* 172, 173).

Properties, &c.—White, deliquescent, plates; soluble in alcohol, and CS_2; soluble in water with production of much heat $[Al^2I^6,Aq] = 178{,}000$ (*Th.* 3, 240). Solution in H_2O on standing over H_2SO_4 gives $Al_2I_6.12H_2O$. Decomposed by heating in O (Schulze, *J. pr.* [2] 21, 40). Forms double salts with alkali iodides; absorbs NH_3; apparently does not combine with H_2S (Weber, *P.* 101, 465; 103, 259).

Aluminium, Nitride of. Al heated in N increases in weight, and heated with molten NaOH evolves NH_3 (Brieglob a. Geuther, *A.* 123, 238). The compound Al_2N_2 was obtained by Mallet (*C. J.* [2] 15, 349) by heating Al with Na_2CO_3 to the highest temperature of a wind furnace for some hours in a graphite crucible,

and treating the residual mass with HClAq. The compound is pale-yellow when amorphous, bright honey-yellow and very lustrous when crystallised; brittle, not hard enough to scratch glass; in moist air it slowly crumbles down to Al_2O_3 with evolution of NH_3; it is dissolved by aqueous alkalis with evolution of NH_3 and solution of Al; fused with KOH or NaOH, an aluminate is formed and NH_3 is given off; heated in air, NH_3 is evolved and Al_2O_3 remains.

Aluminium, Oxide of. [There are some indications of the existence of an oxide containing more O than Al_2O_3 (*v.* Gibson a. Morrison *P.R.S.E.* 119, 146, 152).] Al_2O_3 (*Alumina*) Mol. w. unknown. S.G. (amorphous) 3·725 to 4·152 (Rose, *P.* 74, 429); (crystalline) 3·928. S.H. (corundum, 9°–98°) ·19762; (sapphire, 8°–97°) ·21733 (Regnault, *A. Ch.* [3] 1, 129).

Occurrence.—Native, nearly pure as *corundum, sapphire, topaz, amethyst,* &c.; also in opaque variety as *emery.*

Formation. — I. Amorphous. — 1. By burning powdered Al in oxygen.—2. By ppg. boiling solution of potash-alum by $(NH_4)_2CO_3Aq$, washing, and strongly heating.—3. By strongly heating ammonia-alum.—4. By digesting clays, felspathic rocks, &c., with *con.* KOHAq under pressure, and ppg. by CO_2.—5. By heating a mixture of cryolite and lime in steam, lixiviating, and ppg. by CO_2.—II. Crystalline.—1. By fusing the amorphous Al_2O_3 in the oxyhydrogen flame (Gaudin, *C. R.* 49, 1342).—2. By heating equal parts of potash alum and K_2SO_4 with charcoal (Gaudin, *A.* 103, 92).—3. By fusing together Al phosphate with three or four parts of K_2SO_4 or Na_2SO_4 (Debray, *C. R.* 52, 895).—4. Along with $Al_2O_3.H_2O$, by heating a solution of Al_2O_3 in HClAq to 350° in a closed tube (Sénarmont, *C. R.* 32, 762).—5. By heating to bright redness equal parts of amorphous Al_2O_3 and PbO (Deville a. Caron, *A. Ch.* [4] 5, 104).

Preparation.—The *amorphous* variety may be prepared by heating dry potash-alum for two or three hours to redness, finely powdering the residue, washing with water, mixing with NaOHAq containing $\frac{1}{10}$ as much NaOH as the potash-alum used, drying, strongly heating, and washing with water (Wöhler, *A.* 53, 422; Brunner, *P.* 98, 488). *Crystalline* Al_2O_3 may be prepared by heating to whiteness a mixture of one part amorphous Al_2O_3 with four parts fused borax (Ebelmen, *A. Ch.* [3] 33, 34). Large crystals 1 cm. long were obtained by Deville a. Caron (*A. Ch.* [4] 5, 104) by the action of Al_2F_6 on boric acid at a high temperature. The Al_2F_6 was placed in a graphite crucible, the boric acid being contained in a small Pt basin fixed above the Al_2F_6; the whole was placed in a Hessian crucible and heated in a wind furnace for some time; BF_3 was volatilised and crystals of Al_2O_3 remained.

Properties.—Known in two forms, amorphous and crystalline. The *amorphous* variety is a white, soft, powder; cakes together when strongly heated, and becomes nearly as hard as corundum; infusible except in oxyhydrogen blowpipe; insoluble in water; soluble in acids and aqueous alkalis, but after strongly heating becomes insoluble in acids except *con.* H_2SO_4Aq and *con.* HClAq. The *crystalline* variety forms colourless rhombohedra; insoluble in all acids; nearly as hard as diamond. Both forms are undecomposed by heat, and are unacted on by Cl.

Reactions.—1. With *acids* amorphous Al_2O_3 reacts to form Al salts—*e.g.* $Al_2.3SO_4$.—2. Fused with *potash* or NaOH, or $KHSO_4$, both amorphous and crystalline Al_2O_3 form aluminates (*q. v.*) which are soluble in water.—3. Amorphous Al_2O_3 heated to whiteness with *potassium* is partly deoxidised with formation of an alloy of K and Al. 4. Heated with *sal ammoniac*, Al_2Cl_6 is formed; the same compound is produced by the action of hot BCl_3, or $SiCl_4$.—5. Al_2S_3 is said to be formed by the action of *carbon disulphide* vapour on hot Al_2O_3.—6. *Water* is taken up by slightly heated amorphous Al_2O_3, but no definite hydrates have been thus obtained (*v.* ALUMINIUM, HYDROXIDES OF).

Aluminium, Oxychlorides of. A series of these compounds seems to exist; they may be obtained by the action of a mixture of Al_2Cl_6 vapour and O on Al; the higher the temperature the more O is there in the product; they are soluble in dilute acids and alkalis, and are decomposed by water (Hautefeuille a. Perrey, *C. R.* 100, 1219). Tommasi (*Bl.* [2] 37, 443), describes three compounds of $Al_2O_6H_6$ with Al_2Cl_6 obtained by the action of Al on $CuCl_2Aq$ under different conditions.

Aluminium, Phosphide of. Described by Wöhler (*P.* 11, 160) as a dark grey mass, which decomposes H_2O evolving PH_3; produced by heating powdered Al to redness in vapour of P.

Aluminium, Salts of. *Salts obtained by replacing H of acids by Al.* These salts belong to the form Al_2X_6, or AlX_3, where X = NO_3, $\frac{PO_4}{3}$, $\frac{CO_3}{2}$, $\frac{SO_4}{2}$ &c.; besides these, many basic salts (compounds of normal salts with $Al_2O_3.xH_2O$) are known. Very many Al salts also form double salts; the most characteristic of which are the alums $Al_2.3SO_4.M_2SO_4.24H_2O$, where M = an alkali metal, Ag, or Tl (*v.* ALUMS). The haloid salts, the normal nitrate, sulphate, and acetate, are soluble in water; most of the other normal salts, and almost all the basic salts, are insoluble in water. The soluble salts possess a sweetish, astringent taste. Aqueous solutions of Al salts generally contain more o less free acid, which is not, however, to b detected by the ordinary tests; Erlenmeyer a. Lewinstein (*Z.* 3, 572) add freshly ppd. $Mg.NH_4.PO_4$, which pps. $Al_2(PO_4)_2$, and form $MgSO_4$ and $(NH_4)_2SO_4$, the acid can then b detected by litmus &c. The number of Al salts i not very large; with some acids, *e.g.* sulphurous carbonic, &c., it forms no salts or very unstabl ones which can hardly be obtained pure. Th chief salts—described under BORATES, PHOSPHATES, &c.—are the *borates, nitrates, phosphates, silicates,* and *sulphates*: *v.* also CARBONATES, SULPHITES, SELENATES, &c.

Aluminium, Selenide of. According t Wöhler, Al when heated in Se vapour combines with the latter to form a black powde which is decomposed by H_2O into $Al_2O_3.xH_2$ and H_2Se (*P.* 11, 160).

Aluminium, Silicides of. Al and Si rea in almost all proportions; the products see to be of the nature of alloys. When Al i heated with silicates in presence of a flux, portion of the silica is reduced and combines with part of the Al. An alloy containing 10·3 p.c. Si, called *cast aluminium*, is grey and very brittle; an alloy with 70 p.c. Si still exhibits metallic properties. The alloys of Si and Al are much more easily acted on by reagents than either of the elements which form them.

Aluminium, Sulphide of. Al_2S_3.

If Al is heated to glowing and S is then thrown on to it, a black mass is produced which is decomposed by H_2O with evolution of H_2S. A mixture of Al_2S_3 and Al_2O_3 is obtained by passing CS_2 vapour over red-hot Al_2O_3. When $Al_2.3SO_4$ is heated in H, Al_2O_3 remains and H_2SO_4 is volatilised (Wöhler, *P.* 11, 160). The best method of preparing Al_2S_3 seems to be to pass S vapour over hot Al in a carbon boat placed in a porcelain tube kept full of H. It is described as yellow crystals, with a bitter taste, which melt with difficulty, and are rapidly acted on by water with formation of H_2S and $Al_2O_3.xH_2O$ (Fremy, *A. Ch.* [3] 38, 322; Sabatier, *A. Ch.* [5] 22, 88; Reichel, *J. pr.* [2] 12, 55). Spring (*Bl.* [2] 39, 64) obtained a sulphide of Al by very strongly compressing an intimate mixture of Al and S.

Aluminium, Telluride of. Described by Wöhler as a black powder produced by heating together Al and Te (*P.* 11, 160).

M. M. P. M.

ALUMINIUM AMYLATE *v.* Amyl alcohol.

ALUMINIUM BROMIDE, Action of, on Organic Bodies.—Aluminium bromide assists the bromination of aromatic hydrocarbons. The action appears to be preceded by the formation of a compound $AlBr_36C_nH_{2n-6}$ (Gustavson, *J.* 1877, 400; 1878, 380; *B.* 18, Ref. 208). $AlBr_3$ also combines with butylene; thus, when HBr mixed with C_2H_4 is passed into $AlBr_3$ at 60°, the compound $AlBr_3C_4H_8$ is formed; the same compound is formed from $AlBr_3$ and C_2H_5Br, and by passing HBr into American or Caucasian petroleum containing $AlBr_3$ at 70° (Gustavson, *J. R.* 16, 95; *B.* 17, Ref. 163).

The compound $AlBr_3C_4H_9$ is an oil, insol. in light petroleum or CS_2; it is decomposed by water with formation of unsaturated hydrocarbons and by alkyl bromides at 70° with formation of paraffins (Gustavson, *J. pr.* [2] 34, 161).

Aluminium bromide converts alkyl chlorides into bromides.

ALUMINIUM ISO-BUTYL $C_{12}H_{27}Al$ *i.e.* $Al(C_4H_9)_3$. From Al and $Hg(C_4H_9)_2$. Fuming liquid (Cahours, *J.*, 1873, 522).

ALUMINIUM ISO-BUTYLATE *v. iso*-Butyl alcohol.

ALUMINIUM CHLORIDE, Action on Organic Bodies.—Aluminium chloride is converted by C_2H_4 and HCl at 100° into the compound $AlCl_3C_4H_8$ (G.).

Aluminium chloride added to a mixture of an aromatic hydrocarbon and an alkyl or alkoyl chloride, bromide or iodide, promotes the evolution of HCl, HBr, or HI and is therefore a most powerful agent in organic synthesis as a means of introducing alkyl or alkoyl groups into an aromatic nucleus (Friedel a. Crafts, *C. R.* 84, 1392, 1450; 85, 74, 672; 86, 1368). Thus methyl-benzenes may be formed by this means from benzene and methyl chloride; acetophenone from benzene and acetyl chloride. The operation is performed by dissolving the aromatic hydrocarbon and the haloid derivative in CS_2 or light petroleum, and adding $AlCl_3$ in successive small portions. The reaction is completed by heating on a water-bath. Condensation is also brought about by $AlCl_3$ by the removal of water; thus benzene and Ac_2O form acetophenone; while benzene and phthalic anhydride form benzoyl-benzoic acid. Under the influence of $AlCl_3$ other reactions also occur; thus benzene is converted by oxygen, sulphur, sulphurous acid, and carbonic acid into phenol, phenyl-mercaptan, benzene sulphinic acid, and benzoic acid, respectively.

These reactions are perhaps due to the formation of such compounds as $AlCl_33C_6H_6$ in which the benzene may be supposed to be more unstable than when in the free state; thus, we might imagine the compound to be $AlH_3Cl_3Ph_3$. Molecular changes may, however, take place in the alkyls; thus both *n*- and *iso*-propyl bromides are converted by $AlBr_3$ into the same iso-propyl-benzene; this is because *n*- propyl bromide is changed by $AlBr_3$, into its isomeride (Gustavson, *J.* 1878, 380; *P.* 16, 958).

In the above cases $AlCl_3$ induces the building up of more complicated compounds, but this reaction may be reversed and alkyl groups removed instead of introduced. Thus ethyl-benzene, heated with $AlCl_3$ in a stream of HCl, evolves ethyl chloride and is reduced to benzene (Jacobsen, *B.* 18, 338). When the alkyl chloride is not carried off by a stream of HCl it may act by substitution upon another portion of the hydrocarbon. Thus toluene is converted by boiling with $AlCl_3$ into benzene and xylene (Anschütz a. Immendorff, *B.* 17, 2816). Somewhat similar reductions occur in other cases, the hydrogen being derived from another portion of the hydrocarbon. Thus naphthalene gives naphthalene dihydride, by reduction, and iso-di-naphthyl, by abstraction of hydrogen; benzene gives toluene and ethyl-benzene together with di-tolyl; di-phenyl-methane is reduced to benzene and toluene (Friedel a. Crafts, *B. A.* 1884, 468; *C. R.* 100, 692).

$AlCl_3$ acting upon *n*-propyl iodide gives propylene and HI, which then react, producing propane (Köhnlein, *B.* 16, 560). Aluminium bromide or iodide acting on propyl chloride or iodide at 130° form propylene but no propane (Kerez, *A.* 231, 286). $AlCl_3$ acting upon alcohols and phenols eliminates HCl; thus phenol gives $(PhO)_3Al_2Cl_3$; resorcin gives $(C_6H_4O_2)Al_2Cl_4$; and di-chlorhydrin gives $C_3H_5Cl_2O.AlCl_2$, which crystallises from CS_2. These compounds are at once decomposed by water into the alcohol, $Al(OH)_3$, and HCl (Claus a. Mercklin, *B.* 18, 2932). Acetyl chloride in CS_2 is converted by $AlCl_3$ into a white solid, $C_{12}H_{14}O_6Al_2Cl_8$, whence water produces a liquid $C_5H_8O_2$ (137°) which may be acetyl-acetone (Combes, *C. R.* 103, 814).

ALUMINIUM ETHIDE AlC_6H_{15} *i.e.* $AlEt_3$ (194°). V.D. 4·5 (for 3·9) at 234°. From mercuric ethide and aluminium heated at 100° for some hours (Buckton a. Odling, *Pr.* 14, 20). Liquid; fumes violently in air, soon taking fire. Decomposed by water. *Iodine* forms EtI.

Aluminium iodo-ethide $Al_2C_6H_{15}I_3$ *i.e.* $Al_2Et_3I_3$, (340°–350°), is a fuming liquid formed by action of EtI on Al at 130° (Cahours, *A. Ch.* [3] 58, 5; *A.* 114, 242).

ALUMINIUM ETHYLATE *v.* ALCOHOL.

ALUMINIUM IODIDE, Action on Organic Bodies. AlI_3 turns out Cl displacing it by I, *e.g.* $3CCl_4 + 4AlI_3 = 3CI_4 + 4AlCl_3$ (Gustavson, *A.* 172, 173). Aluminium iodide and aluminium are singly without action on alcohol, but together they react, forming $Al_2I_3(OEt)_3$ and $Al_2(OEt)_6$. One molecule of aluminium iodide may convert very many molecules of aluminium into aluminium ethylate (*v.* ALCOHOL). Other alcohols act similarly (*v.* PROPYL, BUTYL, and AMYL, ALCOHOLS, CRESOL, PHENOL, NAPHTHOL THYMOL), but methyl and iso-propyl alcohols, glycol, and glycerin do not; the latter forms allyl alcohol (Gladstone a. Tribe, *Pr.* 30, 546, *C. J.* 39, 2; 41, 5; 49, 25; Hodgkinson, *C. N.* 1877, 237). Aluminium behaves in a similar way towards water and ether; it does not attack these bodies until after iodine has been added, when it reacts with water thus: $3H_2O + Al = Al(OH)_3 + H_3$, with which may be compared its action on alcohol: $3HOEt + Al = Al(OEt)_3 + H_3$, while with ether it forms aluminium iodo-ethylate and EtI.

ALUMINIUM METHIDE AlC_3H_9 *i.e.* $AlMe_3$ [c. 0°]. (130°). V.D. 2·8 (for 2·5) at 220°; 4 at 160°. From $HgMe_2$ and Al at 100° (Buckton a. Odling, *Pr.* 14, 19). Takes fire in air. Resembles $AlEt_3$. Just above its boiling-point the compound seems to be Al_2Me_6.

ALUMINIUM PROPYL
AlC_9H_{21} *i.e.* $Al(C_3H_7)_3$. (240°-245°).
From $HgPr_2$ and Al (Cahours, *J.* 1873, 518).

ALUMS.—*Double sulphates or selenates having the composition expressed by the general formula* $M_23S(\text{or}Se)O_4.N_2S(\text{or}Se)O_4.24H_2O$, *where* $M = Al, Cr, Mn, Fe, In$, *or* Ga; *and* $N = Na, K, Rb, Cs, NH_4, Ag$, *or* Tl. These salts crystallise in forms belonging to the regular system, usually in octahedra or cubes. The following are the best-known alums:—I. SULPHATES: (1) M = Al, and N = Na, K, Rb, Cs, NH_4, $NH_3(C_2H_5)$, Ag, or Tl; (2) M = Cr, and N = Na, K, or NH_4; (3) M = Mn, and N = K, or NH_4; (4) M = Fe, and N = K, or NH_4; (5) M = Ga or In, and N = NH_4; (6) M_2 = CrAl, and N = K, or NH_4. II. SELENATES: (1) M = Al, and N = Na, K, or NH_4; (2) M = Cr, and N = K, or NH_4. III. MIXED SELENATES AND SULPHATES, $M_23SeO_4.N_2SO_4.24H_2O$: (1) M = Al, and N = K; (2) M = Cr, and N = K; (3) M = Fe, and N = K. IV. MIXED SULPHATES AND SELENATES, $M_23SO_4.N_2SeO_4.24H_2O$: (1) M = Al, and N = K; (2) M = Cr, and N = K; (3) M = Mn, and N = K; (4) M = Fe, and N = K. Besides these, there are certain double salts which resemble, but are not isomorphous with, the alums; of these **pseudo-alums** the most important are the following:—I. Compounds of Al_23SO_4 with (1) $MnSO_4$, (2) $FeSO_4$, (3) $MgSO_4$; each with $24H_2O$. II. Compounds of $Fe_2.3SO_4$ with (1) $MgSO_4$, (2) $CuSO_4$, (3) $ZnSO_4$; each with $24H_2O$. III. $Mn_23SO_4.MgSO_4.24H_2O$.

In naming the alums, if no prefix is used, a double sulphate of aluminium and one of the metals represented by N in the formula is understood; thus potassium alum is

$$Al_23SO_4.K_2SO_4.24H_2O.$$

The sulphates containing no aluminium are spoken of as chromium-sodium alum, iron-ammonium alum, &c. Similarly, the names ammonium selenio-alum, and chromium-potassium selenio-alum are used for the members of Group II. The salts belonging to Groups III. and IV. may be called selenio-sulphuric alums; the individual bodies are best distinguished by their formulæ.

The alums are all soluble in water, their solubility in hot, being considerably greater than in cold, water; (potash alum, S. 3·29 at 0°; S. 22 at 30°; S. 31 at 60°; S. 357 at 100°). The solutions have a styptic taste and an acid reaction. Some of the alums are separated by water into their constituent salts, *e.g.* silver alum, and manganese-ammonium and potassium alums. Others are partially separated; indeed it appears very probable that every alum is to some extent separated into its constituents when dissolved in a considerable quantity of water. Thus, Favre and Valson (*C. R.* 74, 1165) find the heats of solution of one equivalent of aluminium sulphate (1) in water, (2) in a solution of K_2SO_4, and (3) in a solution of $(NH_4)_2SO_4$, to be the same (about −8,000); hence no combination occurs between the two sulphates in the presence of water. Further the heats of solution in water of the alums have large negative values, and in some cases—*e.g.* iron-ammonium alum—this value increases considerably as temperature rises (Favre and Valson, *C. R.* 74, 1016). G. Wiedemann (*P.* 126, 1; 135, 177), by determining the *specific magnetism* (that is, magnetic moment developed by unit magnetising force ÷ mass of salt in unit volume) of various salts in solution, has shown that an aqueous solution of ferric sulphate is partly separated into sulphuric acid and colloidal ferric oxide, and that the amount of this separation increases the larger the quantity of water added; he has also shown that an aqueous solution of iron-ammonium alum behaves almost exactly in the same way as ferric sulphate; hence the separation of the ferric sulphate by the water is independent of the alkaline sulphate; and hence a dilute aqueous solution of this alum is to a large extent separated into its constituent salts. When an aqueous solution of potassium alum saturated at 12° is heated to 100° a precipitate is slowly formed containing varying quantities of Al_2O_3, K_2O, SO_3, and H_2O; even after 30 days the precipitate continues to be produced. The decomposition of the alum is hastened by adding K_2SO_4 to the solution (A. Naumann, *B.* 8, 1630). Chromium-potassium alum exists in two forms; as violet crystals, and as a green non-crystallisable salt. When a solution of the former salt in water is heated to 70°-80° the colour changes to green, and this change is attended with a gradual increase of the volume of the solution; as the green solution cools the colour slowly changes to violet-blue, and the volume of the liquid slowly decreases (Boisbaudran, *C. R.* 79, 1491). The violet crystals change at 300°-350° to the green salt with loss of all their water of crystallisation; this green dehydrated alum is wholly soluble in hot water, but when heated somewhat above 350° it suddenly changes to greenish-yellow and becomes quite insoluble in water (Lowel, *A. Ch.* [3] 44, 313; Siewert, *A.* 126, 86). When a quantity of barium chloride sufficient to precipitate all the acid in a given mass of chromium-potassium alum is added in four equal portions to an aqueous solution of the green form of this alum, the first and second fourths of the barium are at once precipitated, but the rest only very slowly; moreover, the quantity of heat produced during the precipitation of the first and second fourths is much greater than that produced during the subsequent precipitations (Favre and Valson, *C. R.* 74, 1165). Thus,

Gram-units of heat produced.

Excess of $BaCl_2$.	1st fourth.	2nd fourth.	3rd & 4th fourths.
8251	4104	4102	146

These results taken together show that solution in water of the commoner (probably of all) alums is accompanied by partial separation of these compounds into their constituent salts, and also by partial decomposition of these constituents, certainly at least of the sulphate of the heavy metal; and that the amount of this separation and decomposition is increased by increasing the quantity of water, or by raising the temperature.

The alums are dehydrated by the action of heat; at a higher temperature a portion of the acid radicle is usually volatilised, and a double basic sulphate remains, such as native alum stone $Al_23SO_4.K_2SO_4.2Al_2O_3.8H_2O$; at a still higher temperature more acid is removed and a mixture of alkaline sulphate and oxide of Al, Cr, Mn, or Fe remains; the ammonium alums leave a residue of oxide only. For descriptions of the properties of the individual alums *v.* SULPHATES.
M. M. P. M.

DI-ALURIC ACID *v.* DIALURIC ACID.

AMALGAMS. *Alloys of Mercury* (*v.* ALLOYS). Amalgams are formed (1) by direct union of mercury with other metals; *e.g.* amalgams of alkali metals, of Zn, Pb, Sn, Au: (2) by precipitation of other metals from solutions of their salts on mercury; this is often done by placing sodium-amalgam in the solution of a metallic salt, sometimes by electrolysing a metallic solution in presence of mercury; *e.g.* amalgams of Ag, Fe, Co, Ni, Mn, Ba: (3) by precipitation of mercury on another metal, sometimes it is necessary to electrolyse the mercurial solution, making the other metal one of the electrodes; *e.g.* amalgams of Cu, Ag, Au, Pt: (4) by placing the other metal in contact with mercury and a dilute acid; *e.g.* Zn amalgam. The formation of amalgams is not usually attended with any marked thermal change, but in the production of amalgams of the alkali metals much heat is produced. Thus, $[Na, Hg] = 10{,}300$; $[Na, Hg^6] = 21{,}600$; $[K, Hg^{\frac{5}{2}}] = 20{,}300$; $[K, Hg^{12}] = 34{,}200$ (Berthelot, *C. R.* 88, 1110, 1335). In the formation of amalgams of Sn, Pb, and Bi, heat is absorbed. Little or no contraction of volume accompanies the formation of amalgams, except in the cases of Cu, Ag, Sn, Pb, and a few other metals. The relative conductivity for heat of some solid amalgams is considerably greater than that of either of the metals composing them; *e.g.* amalgams of Sn, Zn, and Bi. Many solid amalgams seem to be chemical compounds in definite proportions; thus when various amalgams containing excess of mercury were subjected to a pressure of about 70 tons on the square inch mercury was removed, and definite bodies remained, containing mercury and metal approximately in the ratios expressed by the formulæ CuHg, AgHg, FeHg, Zn_2Hg, Pb_2Hg, PtHg, (Joule, *C. J.* 16, 378). Again, when amalgams of Au, Ag, Cu, Pb, K, and Na, were heated near to, to, or above, the boiling-point of mercury (360°), the following definite amalgams were obtained (De Souza, *B.* 8, 1616; 9, 1050):—

At 310° Au_8Hg Ag[illegible]Hg $Cu_{11}Hg$
„ 360° Au_9Hg $Ag_{11}Hg$ $Cu_{14}Hg$ Pb_8Hg
„ 440° Au_0Hg $Ag_{13}Hg$ $Cu_{16}Hg$ K_2Hg Na_3Hg.

Some of the liquid amalgams may be regarded as solutions of definite compounds in excess of mercury, *e.g.* liquid Na and K amalgams; others as solutions of metals in mercury, *e.g.* some of the iron amalgams. For descriptions of individual amalgams see the articles on the different metals, also MERCURY.
M. M. P. M.

AMALGAMATION. The process of forming *Amalgams, q. v.*

AMALIC ACID $C_{12}H_{14}N_4O_8$ *i.e.* $C_8H_2Me_4N_4O_8$. *Tetra-methyl-alloxantin.*

Formation.—1. On mixing a solution of di-methyl-alloxan with one of di-methyl-dialuric acid, amalic acid is ppd. (Maly a. Andreasch, *M.* 3, 103).—2. A product in the oxidation of caffeïne by chlorine or nitric acid (Rochleder, *A.* 71, 1).—3. By reducing di-methyl-alloxan by H_2S (E. Fischer, *B.* 14, 1912).

Properties.—Transparent colourless crystals. Stains the skin red. V. sl. sol. cold water or alcohol, sl. sol. hot water. Reduces silver salts. It forms deep violet compounds with baryta, KOH, or NaOH.

Reactions.—1. Oxidised by *nitric acid* to di-methyl-alloxan, or, better, by passing *chlorine* into water in which it is suspended.—2. Amalic acid may be *distilled* without leaving a residue, but it is decomposed and in the distillate there is a crystalline acid, $C_{12}H_{14}N_4O_6$, '*desoxyamalic*' acid [260°]. This acid is v. sol. chloroform or glacial acetic acid, sparingly so in cold alcohol, water or ether. Soluble in alkalis but reppd. by HCl. Is partly decomposed when distilled. Reduces boiling ammoniacal $AgNO_3$. Evaporated with HNO_3 it forms dimethyl-alloxan. Chromic mixture converts it into cholestrophane. Hence it is possibly (Fischer a. Reese, *A.* 221, 339):

$$\begin{array}{ccccc} \mathrm{Me.N} & - & \mathrm{CO} & & \mathrm{CO.NMe} \\ | & & | & & | \quad\; | \\ \mathrm{CO} & & \mathrm{HC} & - & \mathrm{CH} \quad \mathrm{CO} \\ | & & | & & | \quad\; | \\ \mathrm{MeN} & - & \mathrm{CO} & & \mathrm{CO.NMe} \end{array}$$

3. *Hydrogen sulphide* forms di-methyl-dialuric acid (M. a. A.).—4. By *boiling with water* in an open vessel di-methyl-oxamide is produced:

$$C_{12}H_{14}N_4O_8 + H_2O + O_3 = 2C_4H_8N_2O_2 + 4CO_2.$$

5. *Ammonia gas* turns it violet, forming *murexoïn*, a crystalline body resembling murexide.—6. From the solution made by heating amalic acid (4 pts.) with *cyanamide* (2 pts.) and water (100 pts.) there separates out, on cooling, crystalline *cyamido-amalic acid* $C_{13}H_{14}N_6O_7$. Long prisms, sl. sol. cold water, v. sol. hot water, insol. alcohol or ether; reduces silver salts, and yields methylamine and an oxalate when boiled with alkalis. It gives off purple vapours when heated, and forms a sublimate (Andreasch, *M.* 3, 433).

AMANITINE *v.* NEURINE.

AMARINE *v.* BENZOIC ALDEHYDE.

AMBER. A fossil resin from *Pinites succinifer*. S.G. 1·05 to 1·10. It contains from 8 to 8 p.c. succinic acid, also a resin [146°] soluble in ether but not in alcohol, a resin [105°] soluble in alcohol and other bodies. There is about 1 p.c. ash (O. Helm, *P.* [3] 11, 229). When amber is distilled, succinic acid and oil of amber are got. The latter (110°–260°) is a mixture of terpenes (Pelletier a. Walter, *A. Ch.* [3] 9, 89).

AMBREÏN. [25°–30°]. Extracted from ambergris by hot alcohol. Ambergris is found in the intestines of the spermaceti whale in tropical climates, and also floating in the sea. Ambreïn is insol. water, v. sol. alcohol or ether, neutral to litmus. It cannot be saponified. It greatly resembles cholesterin (Pelletier, *A.* 6, 24; *J. Ph.* 5, 49).

AMENYL GLYCERIN *v.* TRI-OXY-PENTANE.

AMENYL-VALERIC ACID *v.* DECENOIC ACID.

AMETHENIC ACID $C_7H_{14}O_2$ (185°–230°). By oxidation of diamylene with chromic mixture (Schneider, *A.* 157, 209).

Properties.—A light oil.

Salts.—SrA'_2, 8aq: needles.—ZnA'_2: warts; aqueous solution forms a gelatinous pp. on heating.—AgA': difficultly soluble pulverulent pp.

AMIC ACIDS. Bodies represented by the formula $X''(CO_2H).CO.NH_2$, being at once amide and acid, *e.g.* oxamic acid.

AMIDES. Bodies derived from ammonia by displacing one-third of its hydrogen by a monovalent acid radicle (Gerhardt a. Chiozza, *A. Ch.* [3] 46, 129). When two-thirds of the hydrogen is displaced by a divalent radicle the product is called an imide, but if the same amount of hydrogen is displaced by two monovalent radicles the product is still called an amide. If the whole of the hydrogen is displaced the product is also called an amide unless it is displaced by one trivalent radicle, when it is called a nitrile.

Amides derived from ammonia by displacing one-third of the hydrogen by an acid radicle, *e.g.* $NH_2.CO.X$, may also be looked upon as derived from mono-basic acids, $X.CO.OH$, by displacement of OH by NH_2.

Di-basic acids, $Y''(CO.OH)_2$, form, in a similar way, first amic acids, $Y''(CO.OH)(CO.NH_2)$, then di-amides, $Y''(CO.NH_2)_2$. Thus a di-amide may be considered to be derived from two molecules of ammonia by displacing one-third of the hydrogen by a di-valent acid radicle.

Formation.—1. By action of ammonia on ethers: $X.CO.OEt + NH_3 = X.CO.NH_2 + HOEt$.—2. By the action of ammonia on acid chlorides:

$$X.CO.Cl + 2NH_3 = X.CO.NH_2 + NH_4Cl.$$

3. By the dehydration of ammonium salts: $X.CO.ONH_4 - H_2O = X.CO.NH_2$. The rate at which this decomposition is brought about by heat has been studied by Menschutkin (*C. R.* 98, 1049).—4. By action of NH_3 on anhydrides:

$$(X.CO)_2O + 2NH_3 = X.CONH_2 + X.CO.ONH_4.$$

The anhydrides of di-basic acids are converted by this reaction into amic acids or imides.—5. From nitriles and cold conc. hydrochloric acid $XCN + H_2O = X.CO.NH_2$.—6. From nitriles, hydrogen peroxide, and very dilute KOH (Radziszewski, *B.* 18, 355).—7. Prepared by heating acids with ammonic sulphocyanide for three or four days, *e.g.*:

$$NH_4SNC + 2HOAc = 2AcNH_2 + COS + H_2O$$

(J. Schulze, *J. pr.* [2] 27, 512).

Properties.—The amides are usually solid, and their melting-points serve to identify the several acids. They are neutral to litmus, but form compounds with acids; their typical hydrogen can in many cases be displaced by metals (Ag or Hg). The typical hydrogen can be displaced by alkoyls, by treatment with acid chlorides, but heating with alkyl iodides does not result in the introduction of alkyls unless sodium has been previously introduced. Alkylated amides can be formed by the action of alkylamines upon acid chlorides or ethers.

Reactions.—1. Converted by dehydration (*e.g.* with P_2O_5) into nitriles: $X.CO.NH_2 = X.C{\vdots}N + H_2O$. 2. Converted into acids by boiling *potash*, boiling dilute HCl, fuming HNO_3, or *nitrous acid*:

$$X.CO.NH_2 + HNO_3 = X.CO.OH + H_2O + N_2O$$

(Franchimont, *R.* 2, 343).

$$X.CO.NH_2 + HNO_2 = X.CO.OH + H_2O + N_2.$$

3. One of the typical atoms of hydrogen may be displaced by *halogens*; when *bromine* and *alkalis* are both present, compounds of the form $X.CO.NKBr$ and $X.CO.NKBr_3$ are produced; these readily split up into KBr and cyanic ethers XNCO (Hofmann, *B.* 17, 1406; 18, 2734). 4. *Phosphorus pentachloride* reacts thus:

$$X.CO.NH_2 + PCl_5 = X.CCl_2.NH_2 + POCl_3.$$

The resulting compound splits off HCl giving $X.CCl_2NH_2 = HCl + XCCl{:}NH$ a chloro-imide and $X.CCl{:}NH = HCl + XC{\vdots}N$.—5. PCl_5 acts upon alkylated amides, forming compounds with twice as many carbon atoms in the molecule. Thus $CH_3.CONHEt$ gives $CH_3CCl{:}NEt$ which then acts thus:

$$2CH_3CCl{:}NEt = NEt{:}CCl.CH_2.CMe{:}NEt + HCl.$$

$CH_3.CONHPh$ acts similarly, while $PhCO.NHPh$ and $CCl_3CONHEt$ form only chloro-imides. Formanilide, HCONPhH does not produce $NPh{:}CCl.CH{:}NPh$ but $NPh{:}CH.NPhH$, di-phenyl-formamidine (Wallach, *A.* 184, 1; 214, 193).

The HCl liberated in the decomposition

$$X.CCl_2.NHY = HCl + XCCl{:}NY$$

may often convert undecomposed amide into amidine

$$2X.CO.NHY + HCl = XCO_2H + XC(NY)(NHY)HCl.$$

Amidines may also be formed thus:

$$XCONHY + XCCl_2NHY = XC(NY)(NHY)HCl + XCOCl.$$

6. Heated with *alcohol* they form alkyl-ammonium salts:

$$X.CO.NH_2 + HOEt = X.CO.O.NH_3Et$$
$$X.CO.NHEt + HOEt = X.CO.O.NH_2Et_2$$
$$X.CO.NEt_2 + HOEt = X.CO.O.NHEt_3$$

(Baubigny, *C. R.* 95, 646).—7. $ZnEt_2$ acts thus:

$$X.CO.NH_2 + ZnEt_2 = X.CO.NZn + 2HEt$$
$$Y''.(CO.NH_2)_2 + ZnEt_2 = Y''.C_2O_2N_2H_2Zn + 2HEt.$$

These compounds are decomposed by water, with reproduction of the amide (H. Gal, *C. R.* 96, 1315).—8. *Phenyl-hydrazine* reacts thus: $PhNH.NH_2 + NH_2.CO.X = PhNH.NH.CO.X + NH_3$ (F. Just, *B.* 19, 1201).—9. Dry HCl converts primary into secondary amides:

$$2NAcH_2 + HCl = NAc_2H + NH_4Cl$$

AMIDINES. The name is applied to compounds that contain amidogen and imidogen attached to the same atom of carbon. Thus, $CH_3.C(NH).NH_2$ is called acetamidine, that is to say, an imide derived from acetamide, while $C_6H_5C(NH)NH_2$ is called benz-amidine, the imide of benzamide. Other names for these

bodies are ethenyl amidine, benzenyl amidine, ethenyl imid-amide, benzenyl imid-amide, acet-imid-amide, benz-imid-amide. The advantage of the imido-amide nomenclature is chiefly seen in naming derivatives, thus $CH_3.C(NEt).NH_2$ and $CH_3.C(NH).NEtH$ may be called acet-ethyl-imido-amide, and acet-imido-ethyl-amide, respectively. But the advantage so gained is lost in the great lengthening of the names, and both bodies will therefore be called ethyl-acetamidine in this dictionary. They might be distinguished as tertiary and secondary ethyl-acetamidine respectively.

Dibasic acids can give rise to a variety of amide-imides, for which Wallach (*A.* 214, 256) proposes the following nomenclature:—

$R\left<\begin{matrix}CO.NH_2\\C(NH).NH_2\end{matrix}\right.$ amid-amidine.

$R\left<\begin{matrix}C(NH).NH_2\\C(NH).NH_2\end{matrix}\right.$ amidine.

$R\left<\begin{matrix}CO\\C(NH)\end{matrix}\right>NH$ imid-imidine.

$R\left<\begin{matrix}C(NH)\\C(NH)\end{matrix}\right>NH$ imidine.

Formation.—1. Amidines are formed by the action of amines on thio-amides or nitriles: $Ph.CN + NPh_2H = Ph.C(NH).NPh_2$ (Bernthsen, *A.* 184, 290, 321).—2. By the action of amines on the compounds (X.CCl:NH or X.CCl:NY) formed by the action of PCl_5 on amides (Wallach, *B.* 8, 1575).

Reactions.—1. H_2S forms thio-amides:
$Ph.C(NPh).NPhH + H_2S = Ph.CS.NPhH + H_2NPh$
$Ph.C(NH).NPhH + H_2S = Ph.CS.NPhH + NH_3$.
Another reaction also takes place:
$Ph.C(NH).NPhH + H_2S = Ph.CS.NH_2 + NPhH_2$.
This may be explained by supposing an intermediate compound, $Ph.C.(SH)(NH_2).NPhH$, to be formed by addition of H_2S.

2. CS_2 acts thus:
$Ph.C(NH).NPhH + CS_2 = Ph.CS.NPhH + HNCS$
$Ph.C(NH).NPh_2 + CS_2 = Ph.CS.NPh_2 + HNCS$
$Ph.C(NPh).NPhH + CS_2 = Ph.CS.NPhH + PhNCS$

3. Action of *aceto-acetic ether*, *v.* p. 19.

The reactions of the amidines are further described in such articles as FORMAMIDINE, ACETAMIDINE, BENZAMIDINE, MANDEL-AMIDINE, PHENYL-ACETAMIDINE, and PHENYL-BENZAMIDINE.

AMIDO-ACETANILIDE *v.* Acetyl-PHENYLENE-DI-AMINE.

AMIDO-ACETIC ACID *v.* GLYCOCOLL.

Acetyl derivative v. ACETURIC ACID.

Benzoyl derivative v. HIPPURIC ACID.

AMIDO-ACETO-ACETIC ACID *v.* ACETO-ACETIC ACID.

AMIDO-ACETO-NAPHTHALIDE *v.* ACETYL-NAPHTHYLENE DI-AMINE.

AMIDO-ACETOPHENONES C_8H_9NO *i.e.* $C_6H_4(NH_2).CO.CH_3$ *Amidophenyl methyl ketone.*

o-**Amido-acetophenone** (c. 249°).

Formation.—1. By reduction of *o*-nitro-acetophenone (Gevekoht, *B.* 15, 2086; *A.* 221, 326).—2. By action of conc. H_2SO_4 on a solution of *o*-amido-phenyl-acetylene (Baeyer a. Bloem, *B.* 15, 2154).—3. By boiling *o*-amido-phenyl-propiolic acid with water (B. a. B.).

Preparation.—*o*-Amido-phenyl-acetylene (50 g.) is slowly dropped into conc. H_2SO_4 (600 c.c.) diluted with water (200 c.c.). After half an hour, the mixture is poured upon ice; neutralised with Na_2CO_3; distilled with steam; and the distillate extracted with ether. 50 p.c. of the theoretical yield is got (Baeyer a. Bloem, *B.* 17, 964). *Properties.*—Thick volatile oil.

Oxim [148°] (Munchmeyer, *B.* 20, 512).

Salts. — $B'H_2SO_4$: needles. — $B'HClSnCl_2$: needles, sol. alcohol.— $B'_2H_2PtCl_6$: yellow pp.

Reaction.—By boiling with alcoholic *aceto-phenone* and some NaOHAq it is converted into flavolin or phenyl-methyl-quinoline (O. Fischer, *B.* 19, 1036): $C_6H_4(NH_2).CO.Me + Ph.CO.CH_3 =$

$$H_2O + C_6H_4\left<\begin{matrix}CMe:CH\\ \qquad\ \ \vert\\ N\quad :\ CPh\end{matrix}\right.$$

Acetyl derivative $C_6H_4(NHAc).CO.CH_3$. [77°]. Silky needles (from benzoline). Sol. alcohol, ether, and hot water, sl. sol. cold water.

m-**Amido-acetophenone** [93°]. Formed by reducing the nitro compound by Sn and HCl (Buchka, *B.* 10, 1714; Hunnius, *B.* 10, 2009; Engler, *B.* 11, 932). Short yellow pyramids, sol. alcohol, and ether.

Salt.—B'HCl: long pointed crystals.

p-**Amido-acetophenone** [106°].

Formation.—From the nitro compound (*q.v.*) by Sn and HCl (Drewson, *A.* 212, 162).

Preparation.—Aniline (2 pts.), $ZnCl_2$ (3 pts.), and Ac_2O (5 pts.) are boiled together for 5 hours; the resulting acetyl derivative is saponified. Yield 55 p.c. of the theoretical (Klingel, *B.* 18, 2687).

Properties.—Long fan-like crystals (from water). V. sol. alcohol, ether and hot water, sl. sol. cold water, benzene, and benzoline.

Salts.—B'HCl: needles.—$B'_2H_2PtCl_6$: slender yellow needles.—$B'_2H_2SO_4$: needles.—$B'_2H_2C_2O_4$: crystals, v. sol. alcohol.

Acetyl derivative $C_6H_4(NHAc).CO.CH_3$. [167°]. Small needles, v. sol. alcohol, and hot water, sl. sol. cold water.

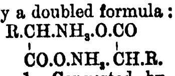
Ethyl derivative v. ETHYL-AMIDO-ACETO-PHENONE.

Benzyl derivative v. BENZYL-AMIDO-ACETOPHENONE.

AMIDO ACIDS.—Amidogen, when attached to carbon in an acid, behaves as it does in amides (*q.v.*) or as in amines (*q.v.*) according as that carbon does or does not belong to carbonyl; in the former case the compound is classed as an amic acid (*q.v.*), the term 'amido acid' is usually restricted to the latter class of bodies.

Formation.—1. From the halogen derivatives of fatty acids, or their ethers, by the action of ammonia.—2. From the nitro-derivatives of (aromatic) acids by reduction.—3. From aldehydes, by action of hydric cyanide and NH_3:
$X.CHO + HCN + NH_3 = X.CH(NH_2)CN + H_2O$.
The nitrile is then converted into amide by conc. HCl, and this is saponified by hot dilute HCl. In this way α-amido acids may be prepared; alkylamido acids can be formed by using alkylamines instead of ammonia (Tiemann, *B.* 14, 1982; Stephan, *C. C.* 1886, 470).

Properties.—Neutral bodies which combine both with acids and bases. Their neutrality is probably due to self-saturation, as may be represented by a doubled formula:



$$\begin{matrix}R.CH.NH_3.O.CO\\ \ \vert\qquad\qquad\ \ \vert\\ CO.O.NH_3.CH.R.\end{matrix}$$

Reactions.—1. Converted by *nitrous acid* into oxy-acids (*v.* p. 57, *l.* 6); di-AZO derivatives (*q. v.*) are first formed, and this formation may be utilised as a test for amido-acids (Curtius, *B.* 17, 959).—2. When heated with *lime* or *baryta*, they split off CO_2 forming amines. This separation of CO_2 sometimes occurs in *formation* 2: thus $C_6H_3(NO_2)Br(CO_2H)$ [4:2:1] reduces to *m*-bromo-aniline (Scheufelen, *A.* 231, 176); $C_6H_3(NO_2)_2CO_2H$ [4:1:2] reduces to *m*-phenylene diamine (Wurster, *B.* 7, 149; Griess, *B.* 7, 1225); while $C_6H_3(NO_2)(CO_2H)_2$ [4:1:2] becomes *m*-amido-benzoic acid. In all these cases the CO_2 is split off from the position *para* to NO_2.—3. AcCl forms acetyl-amido acids. 4. Excess of *methyl iodide*, in presence of KOH, converts (fatty) amido acids into ammonium iodides:

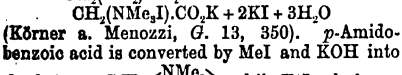
$$CH_2(NH_2).CO_2H + 3MeI + 3KOH = CH_2(NMe_3I).CO_2K + 2KI + 3H_2O$$

(Körner a. Menozzi, *G.* 13, 350). *p*-Amido-benzoic acid is converted by MeI and KOH into the betaïne $C_6H_4{<}\begin{smallmatrix}NMe_3\\CO.O\end{smallmatrix}{>}$, while EtI only forms di-ethyl-amido-benzoic acid (Michael a. Wing, *Am.* 7, 195).—5. Saturated with cupric hydroxide, suspended in hot water, they form blue solutions from which on cooling the copper salt separates. This occurs with leucine, glutamic acid, and aspartic acid. In the case of leucine, a portion remains dissolved, forming a blue mother liquor. In the case of mixtures of amido-acids, the copper salts are not so readily ppd., for they seem to render one another soluble (Schulze a. Barbieri, *J. pr.* [2] 27, 351).—6. The methods of displacing amidogen by halogens in aromatic bodies are mentioned under AMINES.

AMIDO-ACRYLIC ACID $C_3H_5NO_2$ *i.e.* $CH(NH_2):CH.CO_2H$, is formed by the action of alcoholic ammonia on β-chloracrylic acid at 100° (Pinner a. Bischoff, *A.* 179, 97). H. W.

AMIDO-ALCOHOLS or Alkamines (*q. v.*) are formed by action of bases on chlorhydrins or on alkylene oxides, *e.g.*:

$$CH_2Cl.CH_2OH + NH_3 = CH_2(NH_2HCl).CH_2.OH,$$
and



$$\begin{matrix}CH_2\\|\\CH_2\end{matrix}{>}O + NMe_3 + H_2O = CH_2(NMe_3OH).CH_2OH.$$

V. OXY-ETHYL-AMINE, NEURINE, &c.

AMIDO-ALIZARIN *v.* OXY-AMIDO-ANTHRAQUINONES.

DI-AMIDO-AMARINE *v.* *Amarine* under BENZOIC ALDEHYDE.

AMIDO-AMYL ALCOHOL *v.* OXY-AMYL-AMINE.

AMIDO-AMYL-BENZENE $C_{11}H_{17}N$ *i.e.* $C_6H_4(C_5H_{11})NH_2$. (258°) (C.); (260°-265°) (H.). An oil. Formed by heating amyl-aniline hydrochloride at 320° (Hofmann, *B.* 7, 529), or by heating aniline with amyl alcohol and $ZnCl_2$ at 270° (Calm, *B.* 15, 1643).

Salts.—$B'_2H_2SO_4$: silky needles.—$B'_2H_2PtCl_6$: slender orange-yellow needles.

Benzoyl derivative $C_6H_4(C_5H_{11})NHBz$. [c. 149°]. Pearly plates; sol. alcohol, ether, benzene.

AMIDO-ANISIC ACID *v.* *Methyl*-OXY-AMIDO-BENZOIC ACID.

AMIDO-ANISOL *v.* *Methyl*-AMIDO-PHENOL.

AMIDO-ANTHRACENE *v.* ANTHRAMINE.

AMIDO-ANTHRAQUINONES $C_{14}H_9NO_2$. M.w. 223. Three have been described, but theory indicates only two; (*a*) and *m*- are perhaps identical.

***o*-Amido-anthraquinone**

$$C_6H_4{<}\begin{matrix}CO(1)\\CO(6)\end{matrix}{>}C_6H_3.NH_2\ (2).\quad [241°].$$

Formation.—1. By reducing *o*-nitro-anthraquinone (Roemer, *B.* 15, 1790).

Properties.—Ruby-red iridescent needles; may be sublimed. Sol. alcohol, ether, benzene and HOAc, forming orange liquids, v. sl. sol. water. It is a weak base, dissolving in conc. HCl. Converted by nitrous acid into *erythro*-oxy-anthraquinone.

Salt.—B'HCl: unstable white needles.

Acetyl derivative $C_{14}H_7O_2NAcH$ [202°]. Orange-red needles, sol. alcohol and cold HClAq.

(α)-Amido-anthraquinone [254°].

Formation.—1. From bromo-nitro-anthraquinone (Claus a. Hertel, *B.* 14, 980) or from di-bromo-nitro-anthraquinone (Claus a. Dierenfellner, *B.* 14, 1334) by sodium-amalgam.—2. From (α)-nitro-anthraquinone and sodium-amalgam (Böttger a. Petersen, *A.* 166, 149).

Properties.—Red needles, may be sublimed. Sol. benzene and chloroform, sl. sol. alcohol, and ether. Differs from the preceding by insolubility even in fuming HClAq.

***m*-Amido-anthraquinone**

$$C_6H_4{<}\begin{matrix}CO\ (1)\\CO\ (6)\end{matrix}{>}C_6H_3NH_2\ (3).\quad [302°].$$

Formation.—1. From anthraquinone *m*-sulphonic acid and NH_3Aq at 200° (Perger, *B.* 12, 1566; according to Bouchardat, *Bl.* 33, 264, this reaction produces amido-oxy-anthraquinone) 2. From its acetyl derivative, which is got by oxidising acetyl-anthramine by CrO_3 in glacial HOAc (Liebermann, *A.* 212, 61).

Properties.—Red needles. Sol. aqueous HCl, insoluble in alkalis. By the action of HNO_2 and boiling alcohol it is converted into anthraquinone.

Acetyl derivative $C_{14}H_7O_2NAcH$. [257°] (P.); [263°] (L.); colourless needles.

Di-amido-anthraquinones
$C_{14}H_{10}N_2O_2$ *i.e.* $C_{14}H_6O_2(NH_2)_2$.

(α)-Di-amido-anthraquinone [236°].

Formation.—1. From (α)-di-nitro-anthraquinone either (*a*) by ammonic sulphide, (*b*) by aqueous NH_3 at 200°, nitrogen coming off (J. Fischer, *J. pr.* [2] 19, 209), or (*c*) by $SnCl_2$ and NaOHAq (Böttger a. Petersen, *A.* 160, 148). 2. By reduction of tetra-bromo-di-nitro-anthraquinone (Claus a. Hertel, *B.* 14, 981).

Properties.—Red needles (from ether), with greenish reflex (when sublimed). V. sl. sol water, m. sol. alcohol, ether or acetone, v. sol. benzene. The solutions are purple. Hardly soluble in dilute acids; does not form salts.

Reactions.—1. *Nitrous acid* passed into its alcoholic solution forms anthraquinone (B.a.P.). 2. *Nitrous acid* passed into its ethereal solution forms a brownish-violet powder, $C_{14}H_8N_4O_4$, which detonates at about 68° (B.a.P.).—3. *Potash-fusion* produces alizarin (Böttger a. Petersen, *B.* 4, 778), or some similar body (Liebermann, *B.* 4, 231, 779).

(β)-Di-amido-anthraquinone [above 300°].

Formation.—1. By boiling (β)-di-nitro-anthraquinone with $SnCl_2$ and NaOHAq (Schmidt, *J. pr.* [2] 9, 266).

Properties.—Reddish-brown powder; sublimes in dark red needles. Sl. sol. water, v. sol. alcohol, ether, and benzene, forming red solutions. Sol. conc. acids, but re-ppd. unaltered by water.

(γ)-Di-amido-anthraquinone.

Preparation.—Alizarin (20 grms.) is heated for 7 hours at 170° with ammonia solution (200 c.c., S.G. ·915). Alcohol extracts the greater portion (6·2 grms.) of the insoluble residue (7·3 grms.). Water is added to the alcohol, and the pp. is dried *in vacuo* and washed with ether (H. v. Perger, *J. pr.* [2] 18, 135).

Properties.—Indigo-blue powder, which acquires a coppery lustre when rubbed. When HCl is added to its blue alcoholic solution (at 0°), the liquid turns cherry-red and deposits brown-red needles of a hydrochloride, which, however, is so unstable as to be reconverted into the amorphous blue base by merely washing with water. It does not dye mordanted goods.

Reactions.—1. Boiled with *potash* it is converted into oxy-amido-anthraquinone (*q. v.*): $C_{14}H_6O_2(NH_2)_2 + KOH = C_{14}H_6O_2(OK)NH_2 + NH_3$. 2. Similar reaction by boiling HCl.—3. *Fused with potash*, or heated with HCl at 250°, forms alizarin.—4. By passing N_2O_3 into its alcoholic solution until the blue colour is changed to pure yellow, it is converted into erythro-oxy-anthraquinone, which is thrown down when water is added. Yield 95 p.c.

(δ)-Di-amido-anthraquinone

$$(3)\ NH_2.C_6H_3{<}\begin{smallmatrix}CO\ (1)\\ CO\ (2)\end{smallmatrix}{>}C_6H_3.NH_2\ (6).$$

[above 300°].

Formation.—By reducing the corresponding di-nitro-anthraquinone, [above 300°] (Roemer, *H.* 16, 366).

Properties.—Splendid red metallic needles (by sublimation). Sl. sol. alcohol, ether, acetone, and chloroform, with orange colour; v. sl. sol. water. Very weak base.

Reactions.—1. Boiling *potash* has no action. 2. *Diazotisation* followed by boiling with water converts it into anthrarufin (*v.* DI-OXY-ANTHRAQUINONE).

Di-acetyl derivative $C_{14}H_6O_2(NHAc)_2$. Reddish yellow needles, v. sol. alcohol, and ether.

AMIDO-ANTHRAQUINONE SULPHONIC ACIDS

$C_{14}H_9NSO_5$ *i.e.* $C_{14}H_6O_2(NH_2).SO_3H$

o-Amido-anthraquinone sulphonic acid

$$C_6H_4{<}\begin{smallmatrix}CO(1)\\ CO(2)\end{smallmatrix}{>}C_6H_2(NH_2)(SO_3H)\ [1:6:2:4].$$

Formed by reducing nitro-anthraquinone sulphonic acid (Lifschutz, *B.* 17, 899). Silvery needles.

(α)-Amido-anthraquinone sulphonic acid.—Prepared by reducing (α)-nitro-anthraquinone sulphonic acid (Claus, *B.* 15, 1519). Sol. dilute acids, and in hot water, sl. sol. cold water, alcohol, and ether.

Salts.—NaA′ 1½aq: small red needles.—CaA′$_2$ 5aq: red needles.—BaA′$_2$ 3½aq: slender red needles.—CuA′$_2$ 7aq: yellowish-red needles.

(β)-amido-anthraquinone sulphonic acid.—Formed by reducing the lead salt of (β)-nitro-anthraquinone sulphonic acid with H_2S (Claus, *B.* 15, 1520). Red powder; v. sol. water forming a red solution, sl. sol. alcohol, insol. ether. A weak acid.

(α)-Di-amido-anthraquinone sulphonic acid

$C_{14}H_{10}N_2SO_5$ *i.e.* $C_{14}H_5O_2(NH_2)_2SO_3H$. Obtained from (α)-di-amido-anthraquinone by means of H_2SO_4 containing dissolved SO_3 (30 p.c.); ppd. by water. The solution is a splendid red. It may be crystallised from alcohol. Sol. glacial HOAc, and in acetic ether. Insol. ether, benzene or benzoline. On passing nitrous gas into its alcoholic solution anthraquinone (α)-sulphonic acid is formed. *Potash-fusion* forms alizarin.

Salt.—BaA′$_2$: insol. cold water (v. Perger, *J. pr.* [2] 19, 209).

AMIDO-ARACHIC ACID

$C_{20}H_{41}NO_2$ *i.e.* $C_{20}H_{39}(NH_2)O_2$. [59°].

From nitro-arachic acid and $SnCl_2$ (Tassinari, *B.* 11, 2031). Sl. sol. ether, m. sol. alcohol. Combines with neither acids nor bases.

AMIDO-AZO-COMPOUNDS *v.* Azo compounds.

AMIDO-BENZALDEHYDE *v.* AMIDO-BENZOIC ALDEHYDE.

AMIDO-BENZAMIDE *v.* AMIDO-BENZOIC ACID.

AMIDO-BENZ-ANILIDE *v.* AMIDO-BENZOIC ACID.

AMIDO-BENZENE *v.* ANILINE.

Di-amido-benzene *v.* PHENYLENE DI-AMINE.

con-**Tri-amido-benzene** $C_6H_9N_3$ *i.e.* $C_6H_3(NH_2)_3$ [1:2:3]. [103°]. (336° cor.). Obtained by distilling tri-amido-benzoic acid with pounded glass (Salkowsky, *A.* 163, 23). Crystalline; v. sol. water, alcohol, and ether. Its aqueous solution is alkaline and gives with Fe_2Cl_6 first a violet, then a brown pp.; hypochlorites and nitrites give brown pps. Reduces cold ammoniacal $AgNO_3Aq$. H_2SO_4 containing a little HNO_3 forms a blue colour.

Salts.—B′′2HCl: sl. sol. conc. hydric chloride B′′.—H_2SO_4 2aq.

i-**Tri-amido-benzene** $C_6H_3(NH_2)_3$. [1:2:4]. [below 100°]. (c. 340°).

Formation.—1. From (α)-di-nitro-aniline, Sn, and HCl (Salkowsky, *A.* 174, 265).—2. From di-amido-azo-benzene *p*-sulphonic acid by Sn and HCl (Griess, *B.* 15, 2196).—3. From chrysoïdin by reduction (Witt, *B.* 10, 658).—4. From di-nitro-benzene-azo-benzene sulphonic acid by reduction (Janovsky, *M.* 5, 159).

Properties.—Colourless plates. V. sol. water, and alcohol, sl. sol. ether. Gives a red (G.) or green (J.) colour with Fe_2Cl_6Aq.

Salts.—B′′H_2SO_4. Needles or prisms; sl. sol. cold water, v. sl. sol. alcohol.—B′′2HCl [133°]: needles (Hinsberg, *B.* 19, 1253).

s-**Tri-amido-benzene** $C_6H_3(NH_2)_3$ [1:3:5] (?) The tin double salt, $C_6H_3(NH_2)_3(HCl)_3SnCl_2$, of this base may be got from tri-nitro-benzene (got by nitration of di-nitro-benzene) by Sn and HCl (Hepp, *A.* 215, 348). But after removing the tin by H_2S, the hydrochloride of the base resinifies, NH_4Cl being formed, although by evaporation in vacuo over H_2SO_4 a very soluble white hydrochloride may be got. It gives no colour with Fe_2Cl_6.

Tetra-amido-benzene $C_6H_2(NH_2)_4$ [1:2:4:5] Formed by reduction of di-nitro-*m*-phenylene diamine with tin and $SnCl_4$. The base is extremely oxidisable. An aqueous solution of the hydrochloride when treated with Fe_2Cl_6 gives a pp of brown needles of $C_6H_2(NH_2)_2(NH)_2H_2Cl_2$.

Salts.—B$^{iv}H_4Cl_4$: v. sol. water, sl. sol. conc aqueous HCl.—B$^{iv}_2(H_2SO_4)_4$: sparingly solubl

large plates.—$B^{iv}H_2SO_4$: long sparingly soluble needles (Nietzki a. Hagenbach, *B.* 20, 334).

AMIDO-BENZENE SULPHONIC ACIDS $C_6H_7NSO_3$ *i.e.* $C_6H_4(NH_2).SO_3H$. *Aniline sulphonic acids.* In the bromination of these acids Br never takes a position *m* to NH_2 (Limpricht, *A.* 191, 252).

***o*-Amido-benzene sulphonic acid**
$C_6H_4(NH_2)SO_3H$ [1:2]. S. ·1 at 7°.

Formation.—1. From *o*-nitro-benzene sulphonic acid (Berndsen a. Limpricht, *A.* 177, 98). 2. From *m*-bromo-benzene sulphonic acid by nitration and reduction (Thomas, *A.* 186, 128).

Properties.—Dull white crystals like rhombohedra. Also, as HA' ½aq, in transparent shining prisms with many faces. Bromine added to a very dilute solution of the barium salt produces H_2SO_4, tri-bromo-aniline and (1, 4, 5)- bromo-amido-benzene sulphonic acid.

Salts (Bahlmann, *A.* 186, 308).—KA' ½aq: prisms.—AgA': needles.—BaA'_2 (L. a. B.).—BaA'_2 2aq (T.).—PbA'_2 ½aq. S. 3·4 at 6°.

***m*-Amido-benzene sulphonic acid**
$C_6H_4(NH_2)SO_3H$ [1:3]. S. 1·2 at 7°; 1·5 at 15°.

From *m*-nitro-benzene sulphonic acid by reduction (Laurent, *C. R.* 31, 538; Schmitt, *A.* 120, 164; Berndsen, *A.* 177, 82). Also from (1, 2, 4)- bromo-amido-benzene sulphonic acid and HIAq at 120° (Goslich, *A.* 180, 102).

Long slender radiating needles. Also, with 1½aq in monoclinic prisms. Sl. sol. cold water, v. sol. hot water, insol. alcohol, and ether. Aqueous solution turns red in air. When heated it decomposes without fusion.

Reactions.—1. *Bromine* added to an aqueous solution produces no tri-bromo-aniline, but (1, 3, 4, 6)- di-bromo-amido-benzene sulphonic acid, (1, 3, 5, 4, 6)- tri-bromo-amido-benzene sulphonic acid, and bromanil. *Chlorine* acts similarly (Beckurts, *A.* 181, 211).—2. Does not produce quinone when *oxidised* (Meyer a. Stüber, *A.* 165, 168).

Salts: BaA'_2 6aq.—PbA'_2.

Amide $C_6H_4(NH_2).SO_2NH_2$. [142°]. From *m*-nitro-benzene sulphamide, conc. NH_3Aq, and H_2S (Limpricht a. Hybbeneth, *A.* 221, 204). White plates or long needles (from water).

Hydro-chloride.—$C_6H_4(NH_3Cl)SO_2NH_2$. [235°]. Needles.

Nitrous acid, passed into a cold mixture of the amide with a little HNO_3, produces a di-azo nitrate, $C_6H_4(N_2NO_3).SO_2NH_2$, benzene sulphamide, and a diazo-amido compound

$C_6H_4(SO_2NH_2).N_2.NH.C_6H_4.SO_2NH_2$;

the latter, [183°], is insol. water, and is split up by HClAq into $C_6H_4(SO_2NH_2)Cl$, N_2, and $NH_2.C_6H_4.SO_2NH_2$.

***p*-Amido-benzene sulphonic acid**
$C_6H_4(NH_2)SO_3H$ [1:4]. *Sulphanilic acid.* S. ·6 at 6°.

Formation.—1. By heating oxanilide or aniline with H_2SO_4 (Gerhardt, *J. Ph.* [3] 10, 5).—2. By heating aniline with fuming H_2SO_4 at 190° (Buckton a. Hofmann, *C. J.* 9, 259; R. Schmitt, *A.* 120, 129).—3. From aniline and *p*-phenol sulphonic acid (Pratesi, *B.* 4, 970; Kopp, *B.* 4, 978).—4. By reducing *p*-nitrobenzene sulphonic acid.—5. By heating aniline ethyl-sulphate (Limpricht, *A.* 177, 80).

Preparation.—Aniline (93 g.) is slowly poured into H_2SO_4 (50 g.) diluted with water. The solution is evaporated and the dried sulphate is mixed with H_2SO_4 (50 g.) and sand, and heated in a dish, with constant stirring, until it becomes solid. Crystallised from water.

Properties.—Plates or trimetric prisms (with aq); monoclinic (with 2 aq).

Reactions.—1. *Bromine-water* gives tri-bromo-aniline and (1,3,2,5)-di-bromo-amido-benzene sulphonic acid.—2. *Oxidised* to quinone by $K_2Cr_2O_7$ and H_2SO_4Aq (Meyer a. Ador, *A.* 159, 7) or by MnO_2 and H_2SO_4 (Schrader, *B.* 8, 759).—3. $KMnO_4$ converts its potassium salt into the azo derivative $C_6H_4(SO_3K).N_2.C_6H_4.SO_3K$ (Laar, *J. pr.* [2] 20, 264), the corresponding azoxy-compound being also formed (Limpricht, *B.* 18, 1420).—4. PCl_5 forms $C_6H_4(SO_2Cl).NH.POCl_2$ [158°], which is converted by alcohol into $C_6H_4(SO_3Et).NH.PO(OEt)_2$ [102°], and by methyl alcohol into $C_6H_4(SO_3Me).NH.PO(OMe)_2$ [114°]. The former is split up by boiling into alcohol, sulphanilic acid, and hydro-di-ethylic phosphate. *V.* also DI-BROMO-AMIDO-BENZENE SULPHONIC ACID.

Salts.—NaA' 2aq.—KA' 1½aq: triclinic prisms.—NH_4A' 1½aq.—BaA'_2 3½aq.—CuA'_2 4aq.—*Aniline sulphanilate* C_6H_7N2HA'. Gives off all its aniline at 100°.

Acetyl derivative $C_6H_4(NHAc)(SO_3H)$—obtained as the sodium salt by boiling sodium sulphanilate with acetic anhydride. The free acid has not been isolated, as it readily splits off acetic acid on evaporation of its solution. The sodium salt (A'Na) forms small colourless prisms very soluble in water, but less in alcohol (Nietzki a. Benckiser, *B.* 17, 707).

Amido-benzene di-sulphonic acids.

I. $C_6H_7NS_2O_6$, *i.e.* $C_6H_3(NH_2)(SO_3H)_2$. [1:3:4?] From *m*-amido-benzene sulphonic acid and fuming H_2SO_4 at 180° (Drebes, *B.* 9, 552; Zander, *A.* 198, 21).—Rhombic octahedra, v. e. sol. water or alcohol.

Salts.—$(NH_4)_2A''$ aq.—K_2A'' aq.—KHA''.—BaA'' 1½aq.—$BaH_2A''_2$; S. 2·9 at 8°.—PbA'' aq.—$PbH_2A''_2$.

II. $C_6H_3(NH_2)(SO_3H)_2$ 2aq. [1:3:5]. From the corresponding nitro acid by reduction (Heinzelmann, *A.* 188, 167). Four or six sided columns, v. sol. water, and alcohol, insol. ether. *Bromine water* gives a pp. of bromanil.

Salts.—$(NH_4)_2A''$aq.—HNH_4A''*x*aq.—K_2A'' 3aq.—K_2A'' 4aq.—KHA'' aq.—BaA'' 3½aq.—$BaH_2A''_2$ 5aq.—PbA'' 3½aq.—$PbH_2A''_2$ 6aq.—Ag_2A''.

III. $C_6H_3(NH_2)(SO_3H)_2$ [1:2:4]. *Di-sulphanilic acid.*

Formation.—1. By heating sulphanilic acid with fuming H_2SO_4 at 170° for 6 hours (Buckton a. Hofmann, *A.* 100, 164).—2. By heating *o*-amido-benzene sulphonic acid with fuming H_2SO_4 at 180° (Zander, *A.* 198, 17).—3. By reducing the corresponding nitro acid (Heinzelmann, *A.* 188, 170).

Properties.—Minute (red) clumps (from water). V. sol. alcohol, insol. ether. *Bromine water* gives tri-bromo-aniline, bromo-amido-benzene di-sulphonic acid, and di-bromo-amido-benzene sulphonic acid.

Salts.—The acid salts are less soluble in water than the neutral ones.—$(NH_4)_2A''$ aq: small hexagonal prisms.—$NH_4HA''2aq$: clumps.—$K_2A''aq$.—$KHA''aq$: silky needles.—$BaA''3aq$: four-sided plates. — $BaH_2A''_2aq$. — $CaA''2aq$: minute white needles. — $CaH_2A''_2$: slender needles.—$PbA''2aq$.—$PbH_2A''_2aq$: small prisms. — $PbH_2A''_26aq$. — Ag_2A'': prisms. — $AgHA''$: needles or plates.

Di-amido-benzene sulphonic acids $C_6H_8N_2SO_3$. *Phenylene-di-amine sulphonic acids.*

I. $C_6H_3(NH_2)_2(SO_3H)$ [1:2 or 5:3]. S. 1 at 10°. From the corresponding nitro acid (Sachse, *A.* 188, 148).—Rhombic tablets. V. sl. sol. alcohol, insol. ether. Turns brown in air. Metallic salts crystallise with difficulty.

Salts.—$HA'HCl$: needles.—$HA'HClSnCl_2$.—$HA'HBr$.—$H_2A'_2H_2SO_4aq$.—$HA'H_2SO_4\frac{1}{2}aq$.

II. $C_6H_3(NH_2)_2HSO_3$ [1:2:4].

Small colourless needles.

Preparation.—1 By sulphonation of *o*-phenylene-diamine.—2. By reduction of (1:2:4) nitro-amido-benzene sulphonic acid.

Salts.—$A'_2Ba + 5\frac{1}{2}H_2O$: easily soluble thin tables or needles.—$A'_2Ca + 3H_2O$: soluble tables or needles (Post and Hardtung, *B.* 13, 39; *A.* 205, 98).

III. $C_6H_3(NH_2)_2HSO_3$ [1:3:4].

Preparation.—1. By sulphonation of *m*-phenylene-diamine.—2. By reduction of nitro-amido-benzene sulphonic acid [1:3:4].

Dimorphous: monoclinic tables, $a:b:c = 1{\cdot}31:1:1{\cdot}36$, or triclinic prisms, $a:b:c = {\cdot}424:1:{\cdot}928$.

Salts.—A'_2Ba6aq: long soluble prisms. A'_2Ca5aq: soluble prisms or tables (Post a. Hardtung, *B.* 13, 40; *A.* 205, 104).

Di-amido-benzene di-sulphonic acid $C_6H_8N_2S_2O_6aq$ *i.e.* $C_6H_2(NH_2)_2(SO_3H)_2aq$. From the nitro acid by reduction (Limpricht, *B.* 8, 290). V. sol. water.

Salt.—$SnA''aq$: needles.

AMIDO-BENZENE PHOSPHONIC ACID $C_6H_8NPO_3$ *i.e.* $C_6H_4(NH_2)PO(OH)_2$. From the nitro acid, tin, and HCl. Slender needles (from water); v. sl. sol. water, v. sol. HClAq; insol. alcohol and ether. Salts.—$Na_2A''3aq$.—PbA''. CuA''.—Ag_2A'' (Michaelis a. Benzinger, *A.* 188, 282).

DI-AMIDO-BENZHYDROL *v.* DI-AMIDO-DI-PHENYL-CARBINOL.

AMIDO-BENZOIC ACIDS $C_7H_7NO_2$ *i.e.* $C_6H_4(NH_2).CO_2H$. M. w. 137. The following derivatives are described in special articles: NITRO-AMIDO-BENZOIC ACID, CHLORO-AMIDO-BENZOIC ACID, CHLORO-METHYL-AMIDO-BENZOIC ACID, METHYL-AMIDO-BENZOIC ACID, ETHYL-AMIDO-BENZOIC ACID, PHENYL-AMIDO-BENZOIC ACID.

o-Amido-benzoic acid $C_6H_4(NH_2).CO_2H$ [1:2]. *Anthranilic acid.* [144°–145°].

Formation.—1. By reducing *o*-nitro-benzoic acid (Beilstein a. Kuhlberg, *A.* 163, 138).—2. By boiling indigo with KOHAq (Fritzsche, *A.* 39, 83).—3. From (1, 2, 3), or (1, 4, 5)-bromo-amido-benzoic acid by sodium-amalgam (Hübner a. Petermann, *A.* 149, 133).—4. From its acetyl derivative and boiling conc. HCl.—5. From isatoic acid (*q. v.*) and boiling conc. HCl.

Properties.—Plates, or rhombic crystals (Haushofer, *A.* 193, 233). May be sublimed. V. sol. water, and alcohol. Converted by *nitrous acid* into salicylic acid; and by *sodium-amalgam* into NH_3 and benzoic acid. HCl and $KClO_3$ form chloranil (Hofmann, *A.* 52, 65). Its *anhydride* is described as ANTHRANIL.

Salts.—$HA'HCl$: [91°]; needles (Kubel, *A.* 102, 236).— $HA'HNO_3$.— $(HA')_2H_2SO_42aq$: needles [188°].—$(HA')_2H_2SO_4aq$.—$(HA')_2H_2C_2O_4$.—BaA'_2: v. e. sol. water, sl. sol. alcohol.—PbA'_2.—CuA'_2.—AgA'.

Ethyl ether EtA'. (260°). Liquid; its hydrochloride, $EtA'HCl$, [170°], forms needles, insol. ether, and may be sublimed.

Reactions.—1. *Nitrous acid* produces salicylic acid (Gerland, *A.* 86, 143) or diazobenzoic acid (*v.* DI-AZO compounds).—2. KCNO converts the hydrochloride of *o*-amido-benzoic acid into uramido-benzoic acid (*q. v.*); *Potassium sulphocyanide* forms, similarly, thio-uramido-benzoic acid (*q. v.*).—3. *Phenyl cyanate* (*q. v.*) forms $NH_2.C_6H_4.CO.NPh.CO.NPhH$. — 4. *Cyanogen* passed into an aqueous solution forms $C_9H_5N_3O$ (Griess, *B.* 11, 1986), while in an alcoholic solution it forms $C_{10}H_{10}N_2O_2$, [173°] (Griess, *B.* 2, 415). The latter is converted by boiling HCl into $C_8H_6N_2O_2$, [above 350°], which is probably

$$C_6H_4{<}\begin{array}{l}NH.CO\\ \quad\;\;|\\ O.NH,\end{array}$$

since it can be formed by heating *o*-amido-benzoic acid with urea. It forms crystalline nitro- and amido-derivatives.

The compound $C_{10}H_{10}N_2O_2$ ‘ethoxyl cyanamidobenzoyl’ is converted by alcoholic NH_3 at 100° into benzcreatinine (*q. v.*).

The compound $C_9H_5N_3O$ ‘di-cyano-amido-benzoyl,’ may be represented thus:

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.C.CN\end{array}$$

(Griess, *B.* 18, 2417). This body gives the following reactions.—*a.* Strong NH_3Aq converts it into

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.C.CO.NH_2,\end{array}$$

‘carboxamido-cyano-amido-benzoyl.’—*b.* Aqueous ammonium sulphide forms the corresponding

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.C.CS.NH_2.\end{array}$$

—*c.* Baryta water forms

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.C.CO_2H,\end{array}$$

‘carboxy-cyano-amido-benzoyl’; which is converted by dry distillation into

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.CH\end{array}$$

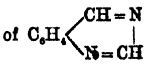
‘carbimido-amido-benzoyl.’—*d.* *m*-amido-benzoic acid produces the anhydride of di-phenyl-guanidine dicarboxylic acid,

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.C.NH.C_6H_4.CO_2H.\end{array}$$

—*e.* *p*-phenylene-diamine produces the anhydride of amido-di-phenyl-guanidine carboxylic acid

$$C_6H_4{<}\begin{array}{l}CO.N\\ \quad\;\;\|\\ NH.C.NH.C_6H_4.NH_2.\end{array}$$

All these bodies may be looked upon as derivatives of



$$C_6H_4{<}\begin{array}{l}CH=N\\ \quad\quad\;\;|\\ N=CH\end{array}$$

which may be called *Quinazoline.*

Formyl derivative $C_6H_4(NHCHO)CO_2H\frac{1}{2}aq$. [168°]. Formed by heating isatoic or *o*-amido-benzoic acid with formic acid (E. v. Meyer a. Bellmann, *J. pr.* [2] 33, 24). Hair-like needles; sol. alcohol, sl. sol. benzene.

Acetyl derivative $C_6H_4(NHAc)CO_2H$. [180°]. Formed by boiling anthranil (*q.v.*) with Ac_2O and treating the product with water (Friedländer a. Henriques, *B.* 15, 2105). Also by oxidation of (*Py.* 3)-methyl-quinoline by $KMnO_4$ (Doebner a. Miller, *B.* 15, 3075).

Preparation. — Acetyl-*o*-toluidine (1 g.) is oxidised by $KMnO_4$ (2 g.) dissolved in water (200 c.c.), the liquid being kept neutral by acetic acid (Bedson a. King, *C. J.* 37, 752).

Properties.—Lustrous leaflets (from water). Prisms (from HOAc). Trimetric, $a:b:c = \cdot982:1:2\cdot803$ (Fletcher).

Salts.—PbA'_2: flocculent pp.—AgA': needles.

Tests.—Solution of sodium salt gives with lead acetate a pp. sol. in acetic acid, with $CaCl_2$ a pp. only on adding alcohol.

Di-acetyl derivative $C_6H_4(NAc_2)CO_2H$. [220°].—AgA'.

Chloro-acetyl derivative $C_6H_4(NH.CO.CH_2Cl).CO_2H$. From acetyl derivative and PCl_5 (Jackson, *B.* 14, 888). Clumps.

Di-chloro-acetyl derivative $C_6H_4(NH.CO.CHCl_2).CO_2H$. [c. 173°]. Prepared like the preceding. Yellowish needles (from water).

Salt.—AgA'.

Benzoyl derivative $C_6H_4(NHBz).CO_2H$. [182°]. By BzCl; or by acting on benzoyl-*o*-toluidine with $KMnO_4Aq$ (Brückner, *A.* 205, 130). Long needles (from alcohol); insol. water.

Salts.—NaA' 4aq.—MgA'_2 4aq.—CaA'_2 3aq.—BaA'_2 3aq.

Oxaloxyl derivative v. CARBOXY-PHENYL-OXAMIC ACID.

Amide $C_6H_4(NH_2)CO.NH_2$. *Amido-benzamide.* [108°]. (300°). From NH_3 and isatoic acid (*q.v.*). White plates (from chloroform). Sl. sol. benzene and ether. Aqueous solution of (1 mol.) of its hydrochloride gives with $NaNO_2$ needles of $C_7H_5N_3O$, [213°]. This compound forms salts, *e.g.* $C_7H_4NaN_3O$, and a methyl ether, $C_7H_4MeN_3O$. The methyl ether, [123°], is also formed from the methylamide of *o*-amido-benzoic acid. The new substance is probably

$$C_6H_4<\begin{matrix}CO.NH\\ |\\ N=N\end{matrix}$$

(Weddige a. Finger, *J. pr.* [2] 35, 262).

Acetyl-amido-benzamide $C_6H_4(NHAc)CONH_2$. [171°]. By Ac_2O. Needles. Forms salts with acids. If kept melted for some time it becomes solid, changing to the anhydro-compound,

$$C_6H_4<\begin{matrix}NH.C.CH_3\\ \|\\ CO.N\end{matrix}$$

Oxy-methyl-quinazoline [228°]. Yellow silky needles (from alcohol). Soluble in hot water. Forms salts with acids.

Formyl-amido-benzamide $C_6H_4(NH.CHO)CONH_2$. [123°]. From dry formic acid and *o*-amido-benzamide. When heated this gives H_2O and an anhydro-compound

$$C_6H_4<\begin{matrix}NH.C.H\\ \|\\ CO.N\end{matrix}$$

Oxy-quinazoline (A. Weddige, *J. pr.* [2] 31, 124).

Anilide $C_6H_4(NH_2)CO.NHPh$. [130°]. From aniline and isatoic acid. Needles (from benzene).

Phenyl-hydrazide $C_6H_4(NH_2)CO.NPh.NH_2$. [170°]. From isatoic acid and phenyl hydrazine in alcoholic solution at 70°. Yellow needles; sol. alcohol and chloroform, v. sl. sol. ether (E. v. Meyer a. Bellmann, *J. pr.* [2] 33, 21).

Hydroxylamide $C_6H_4(NH_2)CO.NH.OH$. [82°]. From isatoic acid (*q.v.*) and hydroxylamine solution (M. a. B.). Yellowish plates, sol. alcohol, ether, and chloroform.

o-Oxy-phenyl ether $C_6H_4(NH_2).CO_2.C_6H_4OH$. [136°]. From isatoic acid and pyrocatechin at 130° (M. a. B.). Needles (from water). Sol. alcohol and ether, sl. sol. water.

***m*-Amido-benzoic acid** $C_6H_4(NH_2).CO_2H$ [1:3]. [173°–174°]. S.G. 1·51 at 4°; S. 2 in cold water, 4 in boiling water or alcohol.

Formation.—1. From *m*-nitro-benzoic acid by reduction (Zinin, *J. pr.* 36, 103; Gerland, *A.* 86, 143; 91, 185; Schiff, *A.* 101, 94; Beilstein a. Wilbrand, *A.* 128, 265).—2. From nitro-phthalic acid, Sn, and HCl (Faust, *Z.* [2] 5, 335).—3. From $C_6H_3Br(NH_2)CO_2H$ [4:3:1] by sodium-amalgam (Raveill, *A.* 222, 180).

Properties.—Crystalline clumps; sweet taste; may be sublimed. Aqueous solutions are browned by air.

Reactions.—1. HCl and $KClO_3$ form chloranil.

2. *Bromine* forms tri-bromo-amido-benzoic acid.

3. *Nitrous acid* forms *m*-di-AZO-benzoic acid.

4. The solution containing *m*-diazo-benzoic acid gives *m*-oxy-benzoic acid on heating.

5. Fusion with *urea* produces uramido-benzoic acid (*q.v.*).

6. Boiling with CS_2 and alcohol produces thio-carbonyl-di-amido-di-benzoic acid, $CS(NH.C_6H_4.CO_2H)_2$ (Merz a. Weith, *B.* 3, 812). This body is also formed by heating *m*-amido-benzoic acid with thio-urea; and, together with thio-carbimido-benzoic acid, by heating *m*-amido-benzoic acid with $CSCl_2$ (Rathke a. Schäfer, *A.* 169, 101). Thio-carbonyl-di-amido-di-benzoic acid does not melt below 300°; it is v. sl. sol. water, m. sol. alcohol or ether; converted by HgO, in presence of KOH (Griess, *A.* 172, 169), into carbonyl-di-amido-di-benzoic acid.

7. $CSCl_2$ produces the last-mentioned body and also thio-carbimido-benzoic acid $SCN.C_6H_4.CO_2H$. This may also be prepared by boiling thio-carbonyl-di-amido-benzoic acid with HCl. It is an amorphous insoluble powder, v. sl. sol. alcohol. Decomposes above 310°. It unites with aniline forming di-phenyl-thio-urea carboxylic acid, $PhNH.CS.NH.C_6H_4.CO_2H$ [191°]. This body is also formed by heating phenyl-thio-carbimide with *m*-amido-benzoic acid at 100° (Merz a. Weith, *B.* 3, 244). It forms slender needles (from water). V. sol. alcohol, and ether, sl. sol. benzene, and benzoline. $AgNO_3$ added to its alkaline solution gives a black pp. of Ag_2S; Fe_2Cl_6Aq gives a yellow pp.; $Pb(OAc)_2$ a white pp.; and $CuSO_4$ a green pp. (Aschan, *B.* 17, 430).

8. *Phosgene* produces carbonyl-di-amido-di-benzoic acid $CO(NH.C_6H_4.CO_2H)_2$ (Sarauw, *B.* 15, 44). This body is also formed by heat-

ing *m*-uramido-benzoic acid (*q. v.*) at 200° (Traube, *B.* 15, 2124). White powder; insol. water, alcohol, and benzene, sol. alkalis.—$BaA''3aq$.—Ag_2A''.—PbA''. Its ether Et_2A'', [161°–162°], is formed by heating *m*-uramido-benzoic ether (Griess, *J. pr.* [2] 4, 294): needles (from dilute alcohol).

9. *Phenyl cyanate* forms on heating, phenyl-uramido-benzoic acid, $NPhH.CO.NH.C_6H_4.CO_2H$. [270°]. Concentric prisms, sol. alcohol, sl. sol. ether, insol. water (Kühn, *B.* 17, 2882).

10. Aqueous KCNO evaporated with *m*-amido-benzoic acid forms *thio-uramido-benzoic acid* $NH_2.CS.NH.C_6H_4.CO_2H$ (Arzruni, *B.* 4, 406).

11. Phenyl cyanate (*q.v.*) forms di-phenyl-urea carboxylic acid $CO_2H.C_6H_4.NH.CO.NPhH$.

12. PCl_5 converts amido-benzoic acid into a white powder which, when extracted with water, yields a solution greatly resembling solutions of albuminous substances. Thus if a little lime-water, NaCl, or $MgSO_4$, be added the liquid may be coagulated by heat, more especially if CO_2 be passed through the solution before heat is applied (Grimaux, *C.R.* 98, 231, 1336).

13. *Cyanogen gas* passed into an aqueous solution forms a dicyanide of amido-benzoic acid, and cyan-carbimid-amido-benzoic acid. Cyanogen passed into an alcoholic solution forms the dicyanide, guanido-di-benzoic acid, and ethoxy-carbimid-amido-benzoic acid.

The *di-cyanide* $(CN)_2NH_2.C_6H_4.CO_2H$, is a yellow, crystalline powder, insol. water, v. sl. sol. alcohol or ether. It does not form metallic salts (Griess, *B.* 11, 1985; Griess a. Leibius, *A.* 113, 332). On distillation it forms *m*-amido-benzonitrile (Griess, *B.* 1, 191; Hofmann, *B.* 1, 194). Boiling KOHAq or HCl converts it into benz-creatine (*q. v.*) (Griess, *B.* 3, 703).

Cyano-carbimidamido-benzoic acid $CO_2H.C_6H_4.NH.C(NH).CN$ forms elliptic plates, v. sl. sol. cold water, sol. acids and alkalis. It reacts as follows:—*a*. Nitrous acid converts it into cyano-carboxamido-benzoic acid, $CO_2H.C_6H_4.NH.CO.CN$. (Griess, *B.* 18, 2415), which forms white plates, insol. cold water, with sweetish taste; boiling water converts it into HCN, CO_2, and carboxy-amido-benzoic acid; dilute NH_3Aq forms uramido-benzoic acid.—*b*. Cold dilute HCl forms small prisms of carbox-amido-carbimidamido-benzoic acid $CO_2H.C_6H_4.NH.C(NH).CO.NH_2$; v. sol. hot water; its aurochloride, $HA'HAuCl_4 1\frac{1}{2}aq$, crystallises in needles (G.).—*c*. Cold aqueous di-methyl-amine forms $CO_2H.C_6H_4.NH.C(NH).C(NH).NMe_2$; six-sided plates, v. sol. hot water, sl. sol. cold water, converted by hot Na_2CO_3aq into *m*-carboxy-phenyl-oxamide NH_3 and NMe_2H.

Guanido-di-benzoic acid $NH{:}C(NH.C_6H_4.CO_2H)_2$ is also formed from thio-carbonyl-di-amido-di-benzoic acid, HgO, and NH_3 (Griess, *A.* 172, 172). It is crystalline. Salts.—BaA''.—$H_2A''HCl$.—$(H_2A''HCl)_2PtCl_4$.

Ethoxy-carbimidamido-benzoic acid, $EtO.C(NH).NH.C_6H_4.CO_2H 1\frac{1}{2}aq$ forms needles (from water), sol. alcohol, and ether; converted by alkalis into alcohol and uramido-benzoic acid; nitrous acid converts it into

Carboxy-amido-benzoic acid mono-ethyl ether $CO_2Et.NH.C_6H_4.CO_2H$ [189°]. This acid is also formed from amido-benzoic acid and $Cl.CO_2Et$. It crystallises in plates (from water). Salts.—$BaA'_2 2aq$.—AgA' (Griess, *B.* 9, 796; Wachendorff, *B.* 11, 701). *Ether* EtA' [101°]; plates (from water). *Amide* $C_{10}H_{10}NO_3NH_2$. [158°] (W.).

Salts.—$HA'HCl$: prisms (Cahours, *A. Ch.* [3] 53, 322).—$(HA'HCl)_2PtCl_4$.—$HA'HClSnCl_2$.—$HA'HBr$.—$HA'HNO_3$.—$(HA')_2H_2SO_4aq$. [225°]. $HA'H_3PO_4$ (Harbordt, *A.* 123, 290).—$BaA'_2 4aq$.—$CaA'_2 3aq$.—CuA'_2—PbA'_2. Needles.—$MgA'_2 7aq$.—AgA'—NaA' (at 100°) (Voit, *A.* 99, 100).—$SrA'_2 2aq$.—ZnA'_2 (when dried at 100°).

Methyl ether.—MeA'. Oil (Chancel, *C. R.* 30, 751).

Ethyl ether.—EtA'. (294°). Liquid, sol. water; from *m*-nitro-benzoic ether. Salts: $EtA'HCl$. [185°]. (Müller, *B.* 19, 1493).—$(EtA'HCl)_2PtCl_4$.—$EtA'HNO_3$: prisms.

Acetyl derivative $C_6H_4(NHAc).CO_2H$. [245°]. *Formation.*—1. By AcCl or by HOAc at 140° (G. C. Foster, *C. J.* 13, 235).—2. From amido-benzoic acid (10 g.) and acetic ether (25 c.c.) at 150°. (Pellizzari, *A.* 232, 148).—3. From amido-benzoic acid and acetamide (P.), or Ac_2O (Kaiser, *B.* 18, 2946). *Properties.*—White powder, v. sol. hot alcohol, sl. sol. hot water, v. sl. sol. cold water and ether. Dissolves in Na_2HPO_4Aq, but re-ppd. by HOAc. May be sublimed. Salts.—$BaA'_2 3aq$: needles.—$CaA'_2 3aq$.—NaA' (at 120°).

Formyl derivative $C_6H_4(NH.CHO).CO_2H$. [225°] (Pellizzari, *G.* 15, 555).

Heptoyl derivative $C_6H_4(NH.C_7H_{13}O).CO_2H$. [202°] (P.)

Glycollyl derivative $C_6H_4(NH.CO.CH_2OH).CO_2H$. [212°]. Gives at 220° the anhydride $<\!\substack{CH_2\\CO}\!>N.C_6H_4.CO_2H$, [248°].

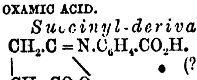
Acetyl derivative. [198°].

Lactyl derivative $CH_3.CH(OH).CO.NH.C_6H_4.CO_2H$. [162°]. Its anhydride melts at [243°] (P.).

Benzoyl-derivative $C_6H_4(NHBz)CO_2H$. [248°]. 1. From amido-benzoic acid and benzamide at 180° for 2 hours.—2. By boiling amido-benzoic acid (2 g.) with benzoic ether (4 c.c.) for 6 hours (Pellizzari, *A.* 232, 150).—3. From amido-benzoic acid and benzanilide at 230° (P.). Minute prisms (from alcohol). Soluble with ease in alcohol, less so in ether or water. Its Ca and Ba salts are soluble. Resolved by hot KOH into benzoic and amido-benzoic acids. *Anilide.*—$C_6H_4(NHBz)CONPhH$. [225°]. By heating $C_6H_4(NBzH)CO_2H$ with aniline for some hours.

Oxaloxyl derivative v. CARBOXY-PHENYL-OXAMIC ACID.

Succinyl-derivative $C_{11}H_9NO_4$ or



$$\begin{array}{l} CH_2.C=N.C_6H_4.CO_2H. \\ |\qquad\diagdown \\ CH_2.CO.O \end{array}$$

(?). [235°]. Formed by melting succinoxyl-amido-benzoic acid, or by fusing succinic and amido-benzoic acids together (Muretow, *J. R.* 4, 295; Pellizzari, *B.* 18, 215). Needles (from alcohol). Sl. sol. cold water. Salts.—$BaA'_2 2aq$.—AgA'.

Succinoxyl derivative $C_{11}H_{11}NO_5$ *i.e.* $CO_2H.CH_2.CH_2.CO.NH.C_6H_4.CO_2H$. [230°]. From the preceding by boiling with water, baryta or ammonia (M.). Plates; m. sol. water. $BaA'' 1\frac{1}{2}aq$.

Succinyl-di-amido-di-benzoic acid

$C_{18}H_{16}N_2O_6$ *i.e.* **$C_2H_4(CO.NH.C_6H_4.CO_2H)_2$**. (?) [c. 300°]. Formed together with $CO_2Et.CH_2.CH_2.CO.NH.C_6H_4.CO_2H$ by heating alcoholic succinic ether with amido-benzoic acid (M.; P.). Also from succinyl-amido-benzoic acid, alcohol, and HCl (M.). White crystalline powder. Soluble in KOHAq. Salts: CaA″7aq. S. :2.—BaA″ 5aq: needles.

Phthalyl derivative $C_{15}H_9NO_4$ *i.e.* $C_6H_4:C_2O_2:N.C_6H_4.CO_2H$. [282°]. Formed together with its ether by heating amido-benzoic acid with phthalic ether (Pellizzari, *B.* 18, 216). Ethyl ether: A′Et. [152°]: radiating needles.

Sebacyl derivative $C_{24}H_{28}N_2O_6$ *i.e.* $C_8H_{16}(CO.NH.C_6H_4.CO_2H)_2$. [275°]. Formed together with $CO_2Et.C_8H_{16}.CO.NH.C_6H_4.CO_2H$ by heating sebacic ether with amido-benzoic acid in alcoholic solution (P.). White powder, sl. sol. in most menstrua.

Amide $C_6H_4(NH_2).CO.NH_2aq$. *Amido-benzamide.* [75°]; when dry [above 100°]. From *m*-nitrobenzamide by ammonium sulphide (H. Schiff, *A.* 218, 185; Chancel, *A.* 72, 274).

Properties.—Large, yellow crystals. Unites with acids forming compounds:—$C_7H_8N_2OHCl$: needles.—$C_7H_8N_2OHNO_3$.—$(C_7H_8N_2OHCl)_2PtCl_4$.—$C_7H_8N_2OAgNO_3$: needles.

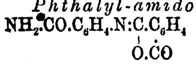
Reactions.—1. Aqueous solutions (even when very dilute) give with *fatty aldehydes* crystalline pps. of the form $R.CH(NH.C_6H_4.CO.NH_2)_2$. These are soluble in alcohol, but give with HNO_3 containing CrO_3 a violet colour. They differ from original amido-benzamides in being no longer basic and in giving no coloured compounds with furfurol solution.—2. Aqueous *salicylic aldehyde* gives yellowish needles of $C_6H_4(OH).CH:N.C_6H_4NH_2$. [186°]. V. e. sol. alcohol or warm water. This compound, *o*-oxy-benzylidene-amido-benzamide, boiled with benzoic aldehyde forms a product $C_{35}H_{26}N_4O_3$, insoluble in water, alcohol, ether, toluene, chloroform or CS_2, but may be crystallised from phenol (2 vols.) and alcohol (1 vol.). It may be considered to be an anhydride of

$$C_6H_5.CH(NH.CO.C_6H_4.N:CH.C_6H_4.OH)_2.$$

Boiled with Ac_2O it takes up 1 molecule of Ac_2O forming small needles. Dilute aqueous NH_3 reproduces the compound $C_{35}H_{26}N_4O_3$. — 3. *Helicin* (2 pts.), *m*-amido-benzamide (1 pt.), and water (10 pts.) form yellowish plates of a glucoside of *o*-oxy-benzylidene-amido-benzamide [113°]: $NH_2.CO.C_6H_4.N:CH.C_6H_4.O.C_6H_{11}O_5\,2aq$. 4. Boiled with an alcoholic solution of *isatin* it forms a crystalline powder [c. 280°] of isat-amido-benzamide:

$NH\left\langle\begin{smallmatrix}C_6H_4\\CO\end{smallmatrix}\right\rangle C:N.C_6H_4.CO.NH_2$. The compounds $NH_2.CO.C_6H_4.N:X$ derived from aldehydes and amido-benzamide are decomposed by heating with aniline into amido-benzamide and PhN:X (Schiff, *G.* 13, 113; *A.* 218, 185).

Phthalyl-amido-benzamide



$$\begin{array}{l} NH_2.CO.C_6H_4.N:C.C_6H_4 \\ \qquad\qquad\qquad\qquad\ |\ \ \ | \\ \qquad\qquad\qquad\qquad O.CO \end{array}$$

[240°–241°]. Got by fusing *m*-amido-benzamide with phthalic anhydride. Bundles of slender needles (from alcohol). V. sl. sol. water. Heated with aniline gives phenyl-phthalimide and amido-benzamide (H. Schiff, *A.* 218, 194).

m-Amido-benzamidoxim $C_6H_4(NH_2).C(NH_2):NOH$. A crystalline solid; formed by reduction of *m*-nitro-benz-amidoxim with $SnCl_2$. Salt.—B′HCl; prisms (Schöpff, *B.* 18, 2472).

Anilide $NH_2.C_6H_4.CO.NPhH$. *Amido-benzanilide.* [129°]. (P.); [114°] (E. a. V.). Formed by heating *m*-amido-benzoic acid with aniline (Piutti, *B.* 16, 1321) or by reducing *m*-nitro-benzanilide (Engler a. Volkhausen, *B.* 8, 35).—Silvery scales (P.) or long needles (from water, E. a. V.). Heated with aniline at 200° it forms two isomerides, $(C_7H_5NO)_n$, one soluble in alcohol, [225°], called 'amido-benzoïde,' and the other an insoluble powder (Piutti, *G.* 13, 339). Salts: $C_{13}H_{12}N_2OHCl$.—$(C_{13}H_{12}N_2O)_2H_2SO_4$

p-**Amido-benzoic acid** $C_6H_4(NH_2)CO_2H$. [186°–187°]. *Amido-dracylic acid.*

Formation.—1. By reducing *p*-nitro-benzoic acid (G. Fischer, *A.* 127, 142; Wilbrand a. Beilstein, *A.* 128, 264). — 2. By boiling its succinoxyl-derivative with HCl (Michael, *B.* 10, 576).

Preparation.—50 pts. of acetyl-*p*-toluidine is suspended in about 2000 pts. of boiling water and oxidised by slowly adding 200 pts. of finely powdered $KMnO_4$. The solution is filtered from MnO_2, the acetamido-benzoic acid ppd. by HCl, and saponified by boiling for an hour with strong HCl (Kaiser, *B.* 18, 2942).

Properties.—Long white needles, not coloured by moist air. When heated with urea it forms $CO(NH.C_6H_4.CO_2H)_2$ (Griess, *J. pr.* [2] 5, 370).

Salts.—BaA'_2: shining laminæ, sol. water.—A′.Pb.OAc, ppd. by $Pb(OAc)_2Aq$ (Ladenburg, *B.* 6, 130). — $(HA')_2H_2SO_4$. — The *copper-salt* is a dark-green pp. (Geitner a. Beilstein, *A.* 139, 1).

Acetyl derivative $C_6H_4(NHAc).CO_2H$. [250°]. Formed from acetyl-*p*-toluidine by $KMnO_4$ (Hofmann, *B.* 9, 1302). Needles, sl. sol. water. Salt: AgA′.

Benzoyl derivative $C_6H_4(NHBz)CO_2H$. [278°]. From benzoyl-*p*-toluidine, CrO_3, and HOAc (Brückner, *A.* 205, 127).—Small needles (from alcohol). Salts.—BaA'_2.—CaA'_2.

Succinoxyl-derivative $CO_2H.CH_2.CH_2.CO.NH.C_6H_4.CO_2H$. [226°]. From *p*-tolyl-succinimide and dilute $KMnO_4$ (Michael, *B.* 8, 577). Yellowish needles, sl. sol. cold water. Salt.—$C_{11}H_{10}NO_5Ag$.

Amide $C_6H_4(NH_2).CO.NH_2$. [179°]. Formed by reducing *p*-nitro-benzamide (Beilstein a. Reichenbach, *A.* 132, 144). Yellow crystals, sl. sol. water.

Di-amido-benzoic acids $C_7H_8N_2O_2$ (Griess, *A.* 154, 325; *B.* 2, 47, 434; 5, 192; 7, 1227; 17, 603; *Pr.* 20, 168; Wurster a. Ambühl, *B.* 7, 213; V. Meyer a. Wurster, *B.* 5, 635; *A.* 171, 62). These acids can be formed by reducing the corresponding di-nitro-, or nitro-amido-, benzoic acids. They are soluble in water, combine both with acids and bases, and split up, when distilled with baryta, into CO_2 and phenylene-diamine.

Nitrous acid converts the (*a*) acid into amido-di-azo-benzoic acid, $C_6H_3(NH_2)\left\langle\begin{smallmatrix}CO\\N_2\end{smallmatrix}\right\rangle O$; the ($\beta$) and ($\gamma$) acids are converted by it into azimido-benzoic acids, $HN_3:C_6H_3.CO_2H$, while the symmetrical acid becomes tri-amido-azo-benzoic acid $C_6H_3(NH_2)(CO_2H).N_2.C_6H_2(NH_2)_2CO_2H$ v. AZO compounds.

s-di-amido-benzoic acid $C_6H_3(CO_2H)(NH_2)_2$aq [1:3:5]. [228°]. S. 1·1 at 8° (Voit, *A.* 99, 106; Hübner, *A.* 222, 85). Colourless needles, neutral to litmus; loses aq at 110°. Very dilute solutions are turned yellow by HNO_2.

Salts.—HA'2HCl: needles.—HA'H_2SO_4—S. 1·05 at 11°.—BaA'$_2$ 1½aq.—AgA' 2aq.

Amide $C_6H_3(CONH_2)(NH_2)_2$ *di-amido-benzamide.* [177°] (V.); [183°] (M.). Needles (Muretow, *Z.* [2] 6, 642). Salt.—$C_7H_9N_3O$2HCl: silky needles. *Di-acetyl-derivative* $C_6H_3(CONAc_2)(NH_2)_2$ 2aq. [Above 270°]. Thin needles, sl. sol. cold water (M.).

(*a*)-*di-amido-benzoic acid* $C_6H_3(CO_2H)(NH_2)_2$. [1:2:5]. Formed also from nitro-isatoic acid by Sn and HCl (Kolbe, *J. pr.* [2] 30, 480). Very small prisms (from water). V. sl. sol. alcohol, ether, and boiling water (G.). The free acid turns blue in air.

Salts.—HA'H_2SO_4: needles, v. sl. sol. water.—HA'2HCl (K.).

(*β*)-*di-amido-benzoic acid* $C_6H_3(CO_2H)(NH_2)_2$ [1:3:4]. [211°] (Salkowski, *A.* 173, 57; Griess, *B.* 5, 856). Plates. Sl. sol. cold water.

Salts.—HA'H_2SO_4: plates; v. sl. sol. hot water.—HA'HCl 1½aq.

(*γ*)-*di-amido-benzoic acid* $C_6H_3(CO_2H)(NH_2)_2$ [1:2:3]. Long needles.

Salt.—$(HA')_2H_2SO_4$ 1½aq: six-sided tables or columns, v. sl. sol. water; Fe_2Cl_6 colours its solution brownish-red.

Tri-amido-benzoic acids $C_7H_9N_3O_2$.

I. $C_6H_2(CO_2H)(NH_2)_3$ ½aq [1:3:4:5]. From di-nitro-amido-benzoic (or chrysanisic) acid (Salkowski, *A.* 163, 12).

Needles (from water). Sl. sol. cold water, v. sl. sol. alcohol, and ether; solution is acid. Heat splits it up into CO_2 and tri-amido-benzene. Its solutions give a brown pp. with Fe_2Cl_6.

Salts.—HA'2HCl: silver-grey needles.—HA'$(HCl)_2SnCl_2$ 3½aq: monoclinic.—HA'H_2SO_4aq: sl. sol. hot water.—HA'2HNO_3.—CaA'$_2$.—ZnA'$_2$ 6aq.

II. $C_6H_2(CO_2H)(NH_2)_3$ [1:2:3:5]. Formed by reduction of *p*-sulpho-benzene-azo-*s*-di-amido-benzoic acid (Griess, *B.* 15, 2200).

Colourless crystals; v. sol. hot water; sl. sol. alcohol, insol. ether. Very readily oxidised.

Salt.—HA'H_2SO_4; small white needles, v. sl. sol. water, insol. alcohol.

References.—CHLORO-, BROMO-, IODO-, NITRO-, and METHYL-, AMIDO-BENZOIC ACIDS and AMIDO-SULPHO-BENZOIC ACID.

AMIDO-BENZOIC ALDEHYDES C_7H_7NO.

o-**Amido-benzoic aldehyde** $C_6H_4(NH_2).CHO$ [1:2]. [40°]. Formed by oxidising its oxim with Fe_2Cl_6 (Gabriel, *B.* 15, 2004).

Preparation.—*o*-nitro-benzaldehyde (3 g.) is digested with $FeSO_4$ (50 g.) and NH_3 at 100° (Friedländer a. Göhring, *B.* 17, 456).

Properties.—Silvery plates; volatile with steam; may be distilled. V. sol. alcohol, ether. and benzene, sl. sol. water, insol. light petroleum.

Salt.—$B'_2H_2PtCl_6$: large yellow prisms (from HClAq).

Reactions.—Very stable towards alkalis, but condensed by acids to $C_{14}H_{12}N_2O$, which is probably $C_6H_4(NH_2).CH:N.C_6H_4.CHO$; this forms small colourless needles [189°], is not volatile with steam, and possesses only weak basic properties; NH_3Aq, conc. HClAq, and hot dilute HClAq reconvert it into amido-benzaldehyde.

Acetyl derivative $C_6H_4(NHAc).CHO$. [71°]. White needles (Friedländer, *B.* 15, 2572).

Oxim $C_6H_4(NH_2)CH:NOH$. [133°]. Formed by reducing *o*-nitro-benzaldoxim (Gabriel, *B.* 14, 2338; 15, 3057; 16, 517). Needles; may be sublimed. Sol. alcohol and ether, sl. sol. water and benzene. Its methyl derivative $C_6H_4(NH_2)CH:NOMe$ melts at [58°] (R. Meyer, *C. C.* 1885, 516). Its acetyl-methyl derivative $C_6H_4(NHAc)CH:NOMe$ [109°], and its di-acetyl derivative $C_6H_4(NHAc)CH:NOAc$ [128°] are crystalline, insol. acids and alkalis.

m-**Amido-benzoic aldehyde.**

Oxim $C_6H_4(NH_2).CH:NOH$. [88°]. Formed by reducing *m*-nitro-benzaldoxim with $FeSO_4$ and NH_3 (Gabriel, *B.* 16, 1997). White felted needles. Sol. alcohol, ether, and hot benzene, sl. sol. cold benzene, and benzoline. Dissolves in acids and alkalis. Salt: $B'_2H_2PtCl_6$; orange yellow tables.

p-**Amido-benzoic aldehyde** $C_6H_4(NH_2).CHO$ [1:4]. [71°]. Formed by action of acids on its oxim. Flat plates, sol. water. With acids it forms red salts.

Acetyl derivative $C_6H_4(NHAc).CHO$. [155°]. Long white needles.

Oxim. — $C_6H_4(NH_2).CH:NOH$. [124°]. Formed by reducing the oxim of *p*-nitro-benzoic aldehyde by ammonium sulphide (Gabriel a. Herzberg, *B.* 16, 2000). Flat yellow crystals, sol. water, alcohol, ether, acids, and alkalis. Its acid solution is resolved, even in the cold, into hydroxylamine and *p*-amido-benzoic-aldehyde. Acetyl derivative $C_6H_4(NHAc).CH:NOH$. [206°]. White plates.

AMIDO-BENZONITRILES $C_7H_6N_2$.

o-**Amido-benzonitrile** $NH_2.C_6H_4.CN$ [1:2]. [103°]. By reduction of *o*-nitro-benzonitrile (Baerthlein, *B.* 10, 1714). Needles; v. sol. water, alcohol, and ether.

m-**Amido-benzonitrile** $NH_2.C_6H_4.CN$ [1:3]. [52°]; (290°).

Formation.—1. By reducing *m*-nitro-benzonitrile (Hofmann, *Z.* [2] 4, 726; Fricke, *B.* 7, 1321).—2. By distilling the dicyanide of *m*-amido-benzoic acid (*v.* p. 157, *l.* 32) (Griess, *B.* 1, 191).—3. By heating *m*-uramido-benzoic acid (*q. v.*) with P_2O_5 (Griess, *B.* 8, 861).

Properties.—Needles or prisms, sl. sol. water, v. e. sol. alcohol.

Salts.—B'HCl.—$B'_2H_2PtCl_6$: four-sided tables.—B'$AgNO_3$: white laminæ.

p-**Amido-benzonitrile** $NH_2.C_6H_4.CN$ [1:4]. [110°] (F.); [74°] (E.). Formed by reducing *p*-nitro-benzonitrile (Engler, *A.* 149, 302), or by distilling *p*-uramido-benzoic acid (F.).—Needles, v. sol. alcohol, ether, and boiling water.—B'HCl.—$B'_2H_2PtCl_6$: needles.

AMIDO-BENZOPHENONES $C_{13}H_{11}NO$. *Amido-di-phenyl-ketones.*

o-**Amido-benzophenone** $Bz.C_6H_4.NH_2$ [1:2]. [106°]. Formed by reducing *o*-nitro-benzophenone with Sn and HCl (Geigy a. Koenigs, *B.*

18, 2466). Yellow plates, or thick crystals, v. sol. dilute acids, alcohol, and ether.

***m*-Amido-benzophenone** $Bz.C_6H_4.NH_2$ [1:3]. [89°]. From *m*-nitro-benzophenone and $SnCl_2$ (G. a. K.).—Yellow felted needles, sol. alcohol, and ether, sl. sol. water.—$B'HCl$: [187°]; long needles.

***p*-Amido-benzophenone** $Bz.C_6H_4.NH_2$ [1:4]. [124°]. *Benzo-aniline.* Prepared by boiling its phthalyl derivative with alcoholic KOH (Doebner, *B.* 13, 1011; Doebner a. Weiss, *B.* 14, 1836). Colourless plates, v. sol. alcohol, ether, and glacial HOAc, sl. sol. cold water. Nitrous acid converts it into *p*-oxy-benzophenone. On fusion with $ZnCl_2$ it loses H_2O forming a compound of the formula $C_{13}H_9N$. The latter is a very stable indifferent substance, crystallising in glistening plates [118°], and distils undecomposed at a high temperature; it is soluble in alcohol, ether, &c., sparingly in hot water, insoluble in cold.

Salts.—$B'_2H_2SO_4$: long sparingly soluble needles.—$B'HCl$, $B'_2H_2C_2O_4$, and $B'HNO_3$ are more soluble.—$(B'HCl)_2PtCl_4$: yellow needles; sl. sol. cold water.

Acetyl derivative $C_6H_5.CO.C_6H_4.NHAc$. [153°]. Long needles. Sol. alcohol, ether, acetic acid and benzene; insol. water.

Benzoyl derivative $C_6H_5.CO.C_6H_4.NHBz$. [152°]. Plates, sol. hot alcohol, sl. sol. cold alcohol, insol. water.

Phthalyl derivative $C_{21}H_{13}NO_3$ *i.e.* $C_6H_5.CO.C_6H_4.N(C_2O_2C_6H_4)$. [183°]. Prepared by the action of BzCl on phthalanil in presence of $ZnCl_2$. Large needles or plates, insol. water, sl. sol. alcohol or ether.

(α)-Di-amido-benzophenone $C_{13}H_8O(NH_2)_2$. [172°]. Prepared by reducing (α)-di-nitro-benzophenone, [190°] itself got from di-nitro-di-phenyl-methane. [183°] (Staedel a. Sauer, *B.* 11, 1747; *A.* 218, 344). White needles.

$B''2HCl$: large tables.—$B''2HClSnCl_2$.—$B''H_2SO_4$.

(β)-Di-amido-benzophenone $C_{13}H_{12}N_2O$. [165°]. *Flavine.*—From di-nitro-benzophenone [149°] by reduction (Chancel a. Laurent, *A.* 72, 281; Prætorius, *B.* 11, 744).—Slender yellow needles (from water).

Salts: $B''H_2Sn_2Cl_6$; plates.—$B''H_2PtCl_6$.

Acetyl derivative $C_{13}H_8O(NHAc)_2$: needles, [227°].

Oxim $(C_6H_4.NH_2)_2C:NOH$: [178°]; crystalline.

Phenyl-hydrazide $(C_6H_4.NH_2)_2C:N_2HPh$: [183°]; yellowish needles (from hot alcohol). (Münchmeyer, *B.* 20, 511).

(γ)-Di-amido-benzophenone, $C_{13}H_8O(NH_2)_2$ [131°]. From the di-nitro-benzophenone [190°] obtained from benzophenone (Staedel, *A.* 218, 349).—Glittering tablets.

Salt.—$B''2HCl$.

Acetyl derivative.—$C_{13}H_8O(NAcH)_2$. [167°]. Tables; insol. water; v. sol. alcohol.

AMIDO-BENZOYL-CARBAMIDE *v.* UREA.

AMIDO-BENZOYL-FORMIC ACID *v.* AMIDO-PHENYL-GLYOXYLIC ACID.

AMIDO-BENZOYL-GLYOXYLIC ACID *v.* QUINISATIC ACID.

AMIDO-BENZOYL-UREA *v.* UREA.

DI-AMIDO-DI-BENZYL $C_{14}H_{16}N_2$ *i.e.* $NH_2.C_6H_4.CH_2.CH_2.C_6H_4.NH_2$. [132°]. From the (*p*) nitro-compound (*q. v.*) by reduction.—Colourless scales (from hot water), v. sl. sol. cold water, v. sol. alcohol; may be sublimed.

Salts: $B''2HCl$.—$B''H_2PtCl_6$.—$B''H_2SO_4$.—$B''H_2C_2O_4$.—$B''(H_2C_2O_4)_2$ 3aq (Fittig a. Stelling, *A.* 137, 262).

AMIDO-BENZYL ALCOHOL C_7H_9NO *i.e.* $NH_2.C_6H_4.CH_2OH$. [1:2]. [82°]. Prepared by the action of zinc dust and HCl upon *o*-nitro-benzyl-alcohol, *o*-nitro-benzoic aldehyde, or anthranil (Friedländer a. Henriques, *B.* 15, 2109). White needles, insol. light petroleum; slightly volatile with steam.

AMIDO-BENZYL-AMINE $C_7H_{10}N_2$ *i.e.* $NH_2.C_6H_4.CH_2NH_2$ [1:4]. (269°). S.G. $\frac{20}{}$ 1·08. *Benzylene diamine.* From acetyl-*p*-nitro-benzyl-amine, Sn, and HCl: the Ac being split off in the operation (Amsel a. Hofmann, *B.* 19, 1287).—Colourless liquid, v. sol. water and alcohol, insol. ether; alkaline, absorbing CO_2 from the air.

Salts.—$B''2HCl$: needles, v. sol. water.—$B''_2(HCl)_4PtCl_4$: flat needles. The *nitrate* and *oxalate* crystallise in long white needles. $AgNO_3$ forms a double salt in large plates.

Di-amido-di-benzyl-amine $C_{14}H_{17}N_3$ *i.e.* $(NH_2.C_6H_4.CH_2)_2.NH$. [106°]. From the nitro compound (Strakosch, *B.* 6, 1060). Needles or plates; may be distilled, but not volatile with steam. **Salts.**—$B'''3HCl$.—$B'''(HCl)_3PtCl_4$.

Tri-amido-tri-benzyl-amine $C_{21}H_{24}N_4$ *i.e.* $(NH_2.C_6H_4.CH_2)_3N$. [136°]. From the nitro compound (S.).—Octahedra (from alcohol); not volatile with steam. Insol. water, v. sol. hot alcohol. Reduced by Sn and HCl to *p*-toluidine and the preceding body.

AMIDO-BENZYL-ANILINE $C_{13}H_{14}N_2$ *i.e.* $NH_2.C_6H_4.CH_2.NPhH$. [88°]. From the nitro-compound by NH_3 and H_2S at 100° (Strakosch, *B.* 6, 1063).—Scales, v. sol. alcohol, ether, and benzene, not volatile with steam. **Salt.**—$B''2HCl$; v. sol. water, less so in HClAq.

AMIDO-BENZYL-BENZENE *v.* AMIDO-DI-PHENYL-METHANE.

AMIDO-BENZYL CYANIDE *v.* NITRILE OF AMIDO-PHENYL-ACETIC ACID.

DI-*p*-AMIDO-DI-BENZYL-MALONIC-ETHYL-ETHER $(C_6H_4(\overset{(4)}{NH_2}).\overset{(1)}{CH_2})_2:C(CO_2Et)$. Obtained by reduction of di-nitro-di-benzyl-malonic ether with $SnCl_2$.

Salts:—$(A''Et_2)H_2Cl_2$: [230°], easily soluble needles.—$(A''Et_2)H_2SO_4$: scales.—$(A''Et_2)H_2C_2O_4$: glistening yellow scales.—$(A''Et_2)H_2Cl_2PtCl_4$: reddish-brown plates (Lellmann a. Schleich, *B.* 20, 436).

AMIDO-BENZYL-PHENOL $C_{13}H_{13}NO$ *i.e.* $C_6H_5.CH_2.C_6H_3(NH_2)(OH)$. [1:3:4]. From the nitro-compound. Scales (Rennie, *C. J.* 41, 221).

DI-AMIDO-BENZYL-TOLUENE $C_{14}H_{16}N_2$. A crystalline powder, obtained by reducing di-nitro-*p*-benzyl-toluene (*q. v.*) (Zincke, *B.* 5, 684).

Salts.—$B''2HCl$.—$B''H_2SO_4$.

AMIDO-BROMO-COMPOUNDS *v.* BROMO-AMIDO-COMPOUNDS.

AMIDO-BRUCINE *v.* BRUCINE.

AMIDO-BUTYL-BENZENE *v.* AMIDO-PHENYL-BUTANE.

AMIDO-BUTYRIC ACIDS $C_4H_9NO_2$.

α-Amido-*n*-butyric acid $CH_3.CH_2.CH(NH_2).CO_2H$. S. 3 at 15°; S. (alcohol) ·18 at 80°. From α-bromo-butyric acid and NH_3Aq (R. Schneider, *A. Suppl.* 2, 71).—Stellate groups of small

laminæ or needles (from alcohol); neutral; sweet taste; insol. ether.

Salts.—HA'HCl; v. sol. water.—HA'HNO$_3$; fern-like groups of silky needles.—(HA')$_2$H$_2$SO$_4$.—HOPb.A'.—AgA'.

β-Amido-*n*-butyric acid $CH_3.CH(NH_2).CH_2.CO_2H$.

Amide $CH_3.CH(NH_2).CH_2.CO.NH_2$. An amorphous mass, obtained by the action of alcoholic NH$_3$ on β-chloro-*n*-butyric ether (Balbiano, *G.* 10, 137; *B.* 13, 312). Its platino-chloride crystallises in orange tables, sl. sol. alcohol.

α-Amido-*iso*-butyric acid $CMe_2(NH_2).CO_2H$.

Formation.—From acetonyl-urea and fuming HCl at 160° (Urech, *A.* 164, 268).—2. From di-acetonamine (Heintz, *A.* 192, 343; 198, 46).

Preparation.—The acetone cyanhydrin, obtained by the action of dilute HCN on acetone, is heated with alcoholic NH$_3$ at 60°, and the product saponified (Tiemann a. Friedländer, *B.* 14, 1971).

Properties.—Plates or tables, v. sol. water, sl. sol. alcohol, insol. ether; sublimes at about 220°.

Salts.—BaA'$_2$ 2aq: needles.—MgA'$_2$: thick prisms.—CuA'$_2$: plates, giving a violet solution.—AgA': needles, sol. water.—HA'HCl 2aq.—HA'HCl.

Nitrile.—$CMe_2NH_2.CN$. The product of the action of alcoholic NH$_3$ on acetone-cyanhydrin (*vid. sup.*).

AMIDO-CAMPHOR *v.* CAMPHOR.

AMIDO-CAMPHORIC ACID *v.* CAMPHORIC ACID.

AMIDO-CAPROIC ACID *v.* LEUCINE, and AMIDO-HEXOIC ACID.

AMIDO-CAPRYL-BENZENE *v.* AMIDO-PHENYL-OCTANE.

AMIDO-CAPRYLIC ACID *v.* AMIDO-OCTOIC ACID.

AMIDO-CARBOSTYRIL $C_9H_8N_2O$ *i.e.*

$C_6H_4{<}\begin{matrix}CH{:}CH\\N(NH_2)\end{matrix}{>}CO$. [127°]. *Anhydride of hydrazido-cinnamic acid; Oxy-amido-quinoline; Amido-pseudo-carbostyril.* Prepared by converting diazo-cinnamic acid by Na$_2$SO$_3$ into $SO_3Na.N_2.C_6H_4.CH{:}CH.CO_2H$, then reducing this substance by acetic acid and zinc dust to $SO_3Na.NH.NH.C_6H_4.CH{:}CH.CO_2H$, boiling this with HCl and then adding KOH (Fischer a. Kuzel, *A.* 221, 278).

Properties.—Slender needles; may be sublimed; sol. alcohol, ether, and hot water. It forms salts with acids.

Reactions.—1. Does not reduce alkaline copper or silver solutions.—2. Nitrous acid converts it, even in the cold, into carbostyril.

γ-Amido-carbostyril. From carbostyril by nitration and reduction (Friedländer a. Lazarus, *A.* 229, 246). Yellow plates (from glacial HOAc). Does not melt below 320°.

Methyl derivative $C_9H_5N(NH_2)(OMe)$. [103°], *amido*-(Py. 3)-*methoxy-quinoline.* Formed from the nitro-compound by SnCl$_2$ (Feer a. Koenigs, *B.* 18, 2397).—Silvery plates; v. sol. alcohol and ether; m. sol. warm water. Its ethereal solution has a bluish fluorescence. KMnO$_4$ oxidises it to methoxy-quinolinic acid [140°]. Dilute HCl at 120° forms (γ)-amido carbostyril.

See also OXY-AMIDO-QUINOLINE.

AMIDO-CHROMATE OF POTASSIUM *v.* ***Amido-chromates*** under CHROMIUM, ACIDS OF.

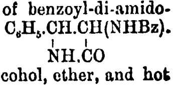
AMIDO-CHRYSANISIC ACID *v.* NITRO-DI-AMIDO-BENZOIC ACID.

AMIDO-CINNAMIC ACIDS $C_9H_9NO_2$.

α-Amido-cinnamic acid $C_6H_5.CH{:}C(NH_2).CO_2H$. Obtained by saponifying its benzoyl derivative.—Silvery plates, decomposing at 240°–250° (Plöchl, *B.* 17, 1619).

Salts.—CuA'$_2$ 2aq: small blue prisms.—(HA')$_2$HCl: flat needles, sl. sol. cold water and alcohol.

Benzoyl derivative $C_6H_5.CH{:}C(NHBz).CO_2H$ [131°]. Formed by heating an acetic acid solution of benzoyl-di-amido-hydrocinnamic lactam



$\begin{array}{l}C_6H_5.CH.CH(NHBz).\\ \qquad NH.CO\end{array}$

Needles or prisms; sol. alcohol, ether, and hot water.

***o*-Amido-cinnamic acid** $NH_2.C_6H_4.CH{:}CH.CO_2H$ [1:2]. [159°].

Preparation.—From *o*-nitro-cinnamic acid (150 g.), crystallised baryta (2100 g.), water (30 litres), and ferrous sulphate (1400 g.), by heating two hours at 100° (Fischer a. Kuzel, *A.* 221, 266; Tiemann a. Opermann, *B.* 13, 2061). Ammonia may be used in place of baryta (Gabriel, *B.* 15, 2294; Friedländer, *A.* 229, 241).

Properties.—Yellow needles; sol. alcohol, ether, and hot water, sl. sol. cold water. Dissolves in aqueous alkalis and acids.

Salts.—HA'HCl; prisms.—BaA'$_2$; prisms.

Ether.—EtA' [78°]. May be distilled. Yellow needles, with yellowish-green fluorescence. Its hydrochloride is sparingly soluble in excess of conc. HCl; its *acetyl derivative*, [137°], forms white needles, which may be distilled (Friedländer a. Weinberg, *B.* 15, 1422).

Ethyl derivative $C_6H_4(NHEt).CH{:}CH.CO_2H$. From the acid (60 g.), KOH (96 c.c. of 20 p.c. solution), alcohol (240 g.), and EtI (60 g.), by boiling (F. a. K.).

Reactions.—1. Long boiling with HClAq forms carbostyril.—2. ZnSO$_4$Aq gives a crystalline pp.—3. AgNO$_3$Aq gives a white pp.—4. CuSO$_4$Aq gives a light green pp.—5. Pb(OAc)$_2$Aq gives a yellow pp.

***m*-Amido-cinnamic acid** $C_6H_4(NH_2).CH{:}CH.CO_2H$ [1:3]. [181°]. The preparation is similar to that of the *o*-compound.

Properties.—Long yellow needles; sol. alcohol, ether, and hot water. Dissolves in aqueous acids and alkalis.

Reactions.—1. CuSO$_4$Aq gives a dull green pp.—2, 3, same as above.—4. Pb(OAc)$_2$Aq gives a white pp. sol. hot water (T. a. O.).

Salts.—HA'HCl: plates.—(HA'HCl)$_2$PtCl$_4$.—HA'HNO$_3$: slender needles.—BaA'$_2$ 2aq: plates.

***p*-Amido-cinnamic acid** $C_6H_4(NH_2).CH{:}CH.CO_2H$ [1:4]. [176°]. Prepared by reducing *p*-nitro-cinnamic ether in alcoholic solution with tin and HCl; yield: 75 p.c. (Miller a. Kinkelin, *B.* 18, 3234). Slender yellow needles, sol. water, alcohol, and ether. Dissolves in aqueous alkalis and acids.

Reactions.—1. CuSO$_4$Aq a brown pp.—2, 3, and 4, the same as for the *m*-compound.

Salts.—HA'HCl.—(HA'HCl)$_2$PtCl$_4$.

Acetyl derivative [260°]. Long needles, sol. hot alcohol, sl. sol. water, v. sl. sol. ether and benzene (Gabriel a. Herzberg, *B.* 16, 2041).

Di-amido-cinnamic acid $C_6H_3(NH_2)_2.CH:CH.CO_2H$. [168°]. Formed by reducing (3:4:1)-nitro-amido-cinnamic acid (Gabriel a. Herzberg, *B.* 16, 2042). Yellow needles, sol. hot alcohol and water, insol. ether, benzene, and benzoline.

AMIDO-COMENIC ACID *v.* COMENIC ACID.

AMIDO-COUMARIN $C_9H_7NO_2$. [168°-170°]. From nitro-coumarin (*q. v.*).—Needles, v. sl. sol. cold water, v. sol. hot water. Salt.—$(B'HCl)_2PtCl_4$ (Frapolli a. Chiozza, *A.* 95, 253).

AMIDO-CRESOL C_7H_9NO. Mol. w. 142. Ten amido-cresols are indicated by theory: four derived from *ortho-*, four from *meta-*, and two from *para-cresol*. The amido-cresols are readily soluble in alcohol and in ether, sparingly so in water. They dissolve in acids and in alkalis. They are formed by reducing nitro-cresols, or from nitro-toluidines by the diazo reaction.

Amido-*o*-cresols $C_6H_3Me(OH)(NH_2)$ [1:2:x].

Amido-*o*-cresol $x = 3$. From nitro-*o*-cresol [69°] (Hofmann a. Miller, *B.* 14, 570; Zincke a. Hebebrand, *A.* 226, 72).

Reaction.—1. When heated with quinone, it forms a red crystalline *Base*, $C_{28}H_{26}N_4O_4$ [285°], v. sl. sol. alcohol, sol. acids; its acetyl derivative, $C_{28}H_{24}Ac_2N_4O_4$, forms orange needles (from dry HOAc).—2. Heated with formic acid it forms a methenyl compound:  $C_6H_3Me\langle\begin{smallmatrix}N\\O\end{smallmatrix}\rangle CH$, [39°], (200°).

Methyl ether $C_6H_3Me(OMe)(NH_2)$. (223°).

Amido-*o*-cresol $x = 4$. [161°]. From nitro-*o*-cresol [108°] (Nölting a. Collin, *B.* 17, 270). Also from acetyl-tolylene-di-amine, $C_6H_3Me(NH_2)(NHAc)$ [1:2:4] (Wallach, *B.* 15, 2831). Colourless plates or needles. Salt.—B'HCl: glittering plates, which sublime as needles.

Acetyl derivatives

$C_6H_3Me(OH)(NHAc)$. [225°]; sol. KOHAq.—$C_6H_3Me(OAc)(NAcH)$. [133°] (Maassen, *B.* 17, 608; Wallach, *A.* 235, 250).

Amido-*o*-cresol $x = 5$. [175°].

Formation. — 1. From nitro-*o*-cresol [85°] (Hirsch, *B.* 18, 1514).—2. From nitroso-*o*-cresol. 3. From sulpho-benzene-azo-*o*-cresol by reducing with Sn and HCl (Nölting a. Kohn, *B.* 17, 865).—White plates or needles; may be sublimed.—CrO_3 gives toluquinone. Salt.—B'HCl.

Amido-*o*-cresol $x = 6$. [124°-128°]. From nitro-cresol [143°]. Stellate groups of needles (Ullmann, *B.* 17, 1962). Salt.—B'HCl.

Undetermined derivatives of amido-o-cresols.

Methyl ether $C_6H_3Me(OMe)(NH_2)$ [1:2:5?]. [53°] (Hofmann a. Miller, *B.* 14, 571).

Ethyl ether $C_6H_3Me(OEt)(NH_2)$ [1:2:x]. From ethyl nitro-*o*-cresol [71°] (Staedel a. Kayser, *A.* 217, 217; *B.* 15, 1134). Salts.—B'HCl 1½aq.—$B'_2H_2SO_4$.—$B'_2H_2PtCl_6$. *Acetyl derivative* $C_6H_3Me(OEt)(NHAc)$. [108°]. Trimetric plates (from water); tables (from ether); cubes (from benzene).

Amido-*m*-cresols $C_6H_3Me(OH)(NH_2)$ [1:3:x].

Amido-*m*-cresol $x = 6$. [151°]. From sulpho-benzene-azo-*m*-cresol by reduction (Nölting a. Kohn, *B.* 17, 367). White warts. On oxidation with CrO_3 it gives toluquinone.

Undetermined derivative of an amido-m-cresol.

Ethyl ether $C_6H_3Me(OEt)(NH_2)$ [1:3:x]. An oil formed by reducing ethyl-nitro-*m*-cresol [54°] (Staedel, *A.* 217, 219). Salt.—$B'_2H_2C_2O_4$. Acetyl derivative. [114°]. Mass of needles (from water).

Amido-*p*-cresols $C_6H_3Me(OH)(NH_2)$ [1:4:x].

Amido-*p*-cresol $x = 2$. [144°].

Formation. — 1. From nitro-*p*-cresol [78°] (Knecht, *A.* 215, 91).—2. From nitro-toluidine $C_6H_3Me.(NH_2)(NO_2)$ [1:4:2] (Wallach, *B.* 15, 2833).

Properties.—Colourless plates by sublimation.

Acetyl derivatives

$C_6H_3Me(OH)(NHAc)$ [178°]; sol. KOHAq.—$C_6H_3Me(OAc)(NHAc)$ [129°] (Maassen, *B.* 17, 608).

Methyl ether $C_6H_3Me(OMe)(NH_2)$. [47°]. From the nitro-compound (K.); needles, volatile with steam.

Amido-*p*-cresol $x = 3$. [135°].

Formation. — 1. From nitro-*p*-cresol [33°] (Wagner, *B.* 7, 1270; Hofmann a. Miller, *B.* 14, 572).—2. By reducing benzene-azo-*p*-cresol or sulpho-benzene-azo-*p*-cresol (Nölting a. Kohn, *B.* 17, 360).

Properties.—White plates or needles; gives a red colour with Fe_2Cl_6. Salt.—B'HCl.

Reactions.—1. Gives a methenyl derivative when heated with formic acid (H. a. M.).—2. Gives, when heated with Ac_2O and NaOAc, an ethenyl derivative which is converted by boiling dilute H_2SO_4 into an acetyl derivative.

Acetyl derivative [160°]. Long needles.

Methyl ether $C_6H_3Me(OMe)(NH_2)$ [38°].

Ethyl ether $C_6H_3Me(OEt)(NH_2)$. [41°]. From the nitro-compound (Staedel a. Kayser, *B.* 15, 1134). Needles (from water) or plates (from other solvents). Salts.—B'HCl 1½aq.—$B'_2H_2SO_4$ 2aq. *Acetyl derivative* [107°].

Di-amido-*p*-cresol.

Ethyl ether $C_6H_2Me(OEt)(NH_2)_2$ [1:4:3:5]. From the nitro-compound (Staedel a. Kayser, *A.* 217, 221). Pleasant-smelling oil—B'HCl: silky needles.

Di-amido-cresol $C_6H_2Me(OH)(NH_2)_2$ [1:x:2:4]. From amido-toluene-azo-amido-cresol (Graeff, *A.* 229, 349); decomposes when liberated from its salts.—$B''H_2SO_4$aq; slender grey needles (from alcohol-ether).

AMIDO-CRESYL- *v.* AMIDO-TOLYL-.

AMIDO-CROTONIC ETHER. A name applied to the imide of aceto-acetic ether (*v.* p. 19).

AMIDO-CUMENE *v.* CUMIDINE.

Di-amido-cumene $C_9H_{14}N_2$ *i.e.* $Pr.C_6H_3(NH_2)_2$. [47°]. From the nitro-compound (Hofmann, *J.* 1862, 354).

Di-amido-pseudo-cumene $C_6HMe_3(NH_2)_2$ [1:3:4:5:6]. [92°]. *Formation.*—1. By reducing nitro-pseudo-cumidine [47°] (Edler, *B.* 18, 630). 2. By reducing amido-azo-cumene (Nölting a. Baumann, *B.* 18, 1147). *Properties.*—Needles or plates; gives with Fe_2Cl_6 a brownish-red colour and a quinone-like smell; also gives Ladenburg's aldehydine reaction.

AMIDO-ψ-CUMENOL $C_9H_{13}NO$ *i.e.* $C_6HMe_3(OH)(NH_2)$ [1:3:4:6:2] [167°]. *Amido-pseudo-cumenol; Oxy-cumidine.* Obtained by reducing benzene-azo-ψ-cumenol (Liebermann a. Kostanecki, *B.* 17, 886); or nitro-ψ-cumenyl nitrate (Auwers, *B.* 17, 2980). White needles (by sublimation); sol. KOHAq. Fe_2Cl_6 gives a red colouration. *Di-acetyl derivative* $C_6HMe_3(OAc)(NHAc)$, [186°]: needles.

AMIDO-CUMINIC ACID $C_{10}H_{13}NO_2$

m-Amido-cuminic acid $Pr.C_6H_3(NH_2)CO_2H$ [1:2:4]. [129°]. *Amido-iso-propyl-benzoic acid.* Prepared by reducing *m*-nitro-cuminic acid [158°] (Paterno a. Fileti, *G.* 5, 383; Lippmann a. Lange, *B.* 13, 1661).—Tables; some of it occasionally crystallises from water in thin plates [104°] (Fileti, *G.* 10, 12). Fe_2Cl_6 give a violet-blue colouration with the hydrochloride. EtI at 100° gives a syrupy *ethyl-amido-cuminic acid.*

Salts.—AgA′: white pp.—$ZnA'_2$3aq: needles. HA′HCl.—$(HA'HCl)_2PtCl_4$.—$(HA')_2H_2SO_4$.

Acetyl derivative. [248°-250°]. Slender needles, sl. sol. boiling alcohol, saponified by water at 230°.

Ethyl ether EtA′. Heavy oil.

Nitrile $Pr.C_6H_3(NH_2).CN$. [45°]. (305°). From nitro-cumino-nitrile.—Needles (from water) (Czumpelik, *B.* 2, 183). **Salt.**—$(B'HCl)_2PtCl_4$.

o-Amido-cuminic acid $Pr.C_6H_3(NH_2).CO_2H$. [1:3:4]. [115°]. Prepared by reducing *o*-nitro-cuminic acid with $FeSO_4$ and NH_3 (Widman, *B.* 19, 270).—Plates or tables.

Acetyl derivative $C_{10}H_{12}AcNO_2$. [246°]. Slender needles, sl. sol. alcohol, and ether; may be sublimed (Widman, *B.* 16, 2579).

Di-amido-cuminic acid $C_{10}H_{14}N_2O_2$ *i.e.* $Pr.C_6H_2(NH_2)_2CO_2H$. [192°]. Formed by reducing di-nitro-cuminic acid (Boullet, *C. R.* 43, 399; Lippmann, *B.* 15, 2141).—Yellowish plates, sol. hot water, alcohol, ether, alkalis and acids. Crystallises from water with aq.

Salts.—AgA′aq.—HA′HCl aq: large prisms.

AMIDO-CUMYL-ACRYLIC ACIDS $C_{12}H_{15}NO_2$

I. $Pr.C_6H_3(NH_2).CH:CH.CO_2H$ [1:3:4]. [165°]. From the nitro-acid, $FeSO_4$, and NH_3 (Widman, *B.* 19, 262).—Flat yellow prisms (from alcohol). **Salt.**—HA′HCl 3aq: very slender needles, v. sl. sol. water; converted by boiling water into cumostyril or (B. 3)-iso-propyl-(Py. 3)-oxy-quinoline [169°]. *Acetyl derivative* $PrC_6H_3(NHAc).CH:CH.CO_2H$, [220°]: very thin needles (from alcohol).

II. $PrC_6H_3(NH_2).CH:CH.CO_2H$ [1:2:4]. [165°]. From the nitro-acid (Widman, *B.* 19, 415). Six-sided tables (from ether). Warm H_2SO_4 gives a magenta colour. **Salts.**—HA′HCl: flat needles.—$(HA'HCl)_2PtCl_4$2aq.—$(HA')_2H_2SO_4$5aq. *Acetyl derivatives* $C_{12}H_{14}AcNO_2$, [240°]: needles (from alcohol).—$C_{12}H_{13}Ac_2NO_2$. [236°].

AMIDO-ψ-CUMYLENE-ACETAMIDINE

$C_{11}H_{15}N_3$ *i.e.*

$C_6Me_3(NH_2)\left\langle{N \atop NH}\right\rangle CMe$ [1:3:4:2:$\frac{5}{6}$].

Ethenyl-tri-amido-tri-methyl-benzene. [215°-218°]. From acetyl-di-nitro-pseudo-cumidine by reduction with Sn and HCl (Auwers, *B.* 18, 2663).—Rosettes of plates or yellowish prisms (from water) containing 2aq.

Salts. — B″2HClaq. — B″HCl 2aq. — $B''H_2PtCl_6$ aq.

AMIDO-CUMYLPHENYLKETONE *v.* Phenyl amido-cumyl ketone.

***m*-AMIDO-CUMYL-PROPIONIC ACID** $C_{12}H_{17}NO_2$ *i.e.* $PrC_6H_3(NH_2).CH_2.CH_2.CO_2H$ [1:3]. [103°-105°]. From *m*-amido-cumyl-acrylic acid, NaOHAq, and sodium-amalgam (Widman, *B.* 19, 418). *Acetyl derivative* $C_{12}H_{16}AcNO_2$, [168°]; prisms (from alcohol).

AMIDO-DI-CYANIC ACID $C_2H_3N_3O$ *i.e.* $NH_2.CO.NH.CN$ or $HN:C\left\langle{NH \atop NH}\right\rangle CO$. *Allophano-nitrile; carbonyl guanidine; carbimido-cyanamide.*

Formation.—1. From di-cyano-di-amide and baryta-water.—2. From potassic cyanate and cold aqueous cyanamide (Hallwachs, *A.* 153, 239; Wunderlich, *B.* 19, [illegible]48).

Properties.—Plates. It decomposes carbonates and behaves as a strong acid. Produces biuret when warmed with H_2SO_4 (1 vol.) and water (2 vols.) at 70° (Baumann, *B.* 8, 708).

Salts.—$NaC_2H_2N_3O$.—KA′.—BaA'_2 3aq.—CuA'_2 4aq.—CuC_2HN_3O 2aq.—AgA′.

AMIDO-CYANURIC ACID *v.* Ammelide.

Di-amido-cyanuric acid *v.* Ammeline.

AMIDO-CYMENE *v.* Cymidine.

Diamido-cymene $C_6H_2MePr(NH_2)_2$[1:4:3:6]. *Hydrochloride.* Formed by reducing the di-oxim of thymoquinone (Liebermann a. Ilinski, *B.* 18, 3200).

AMIDO-DRACYLIC ACID = *p*-Amido-benzoic acid.

DI-AMIDO-DURYLIC ACID *v.* Di-amido-tri-methyl-benzoic acid.

AMIDO-ETHANE *v.* Ethylamine.

Di-amido-ethane *v.* Ethylene di-amine.

AMIDO-DI-ETHYL-ACETIC ACID *v.* Amido-hexoic acid.

AMIDO-ETHYL ALCOHOL *v.* Oxyethyl-amine.

AMIDO-ETHYL-BENZENE *v.* Amido-phenyl-ethane.

AMIDO-ETHYL METHYL KETONE *v* Methyl amido-ethyl ketone.

DI-AMIDO-DI-ETHYL OXIDE ×$C_4H_{12}N_2O$ *i.e.* $(CH_3.C(NH_2)H)_2O$.

Di-amido-ether. The very unstable hydrochloride (B′2HCl) of this body is formed by passing NH_3 into an ethereal solution of $(CH_3.CHCl)_2O$ (Hanriot, *A. Ch.* [5] 25, 224).

DI-AMIDO-DI-ETHYL-DIPHENYL $C_{16}H_{20}N_2$ *i.e.* [4:3:1] $NH_2.C_6H_3Et.C_6H_3Et.NH_2$ [1:3:4] (?). Formed by the action of $SnCl_2$ and HCl or H_2SO_4 on an alcoholic solution of *o*-azo-ethyl-benzene.—$B''H_2SO_4$: needles, sl. sol. water, m. sol. alcohol.

Acetyl derivative $C_{16}H_{16}(NHAc)_2$. [307°]. White needles (by sublimation), sl. sol. alcohol, sol. HOAc.

An isomeric di-amido-di-ethyl-diphenyl is formed similarly from *p*-azo-ethyl-benzene. Its sulphate is a white amorphous powder (G. Schultz, *B.* 17, 474).

AMIDO-ETHYL-TOLUENE *v.* Amido-Tolyl-ethane.

AMIDO-ETHYL-TOLUIDINE *v.* Ethyl-tolylene diamine.

AMIDO-ETHYL-*m*-URAMIDO-BENZOIC ACID $C_{10}H_{13}N_3O_3$ *i.e.* $NH_2.C_2H_4.NH.CO.NH.C_6H_4.CO_2H$. Formed by the action of ethylene diamine upon cyano-carboxamido-benzoic acid (*v.* Amido benzoic acid). White prisms, sl. sol. cold water. **Salt.**—HA′HCl $2\frac{1}{2}$aq (Griess, *B.* 18, 2416).

AMIDO-FLAVOLINE *v.* Flavaniline.

AMIDO-FLUORENE *v.* Fluorene.

AMIDO-FORMIC ACID *v.* Carbamic acid.

AMIDO-FURFUR-BUTYLENE OXIDE

$C_8H_{11}NO_3$ *i.e.*

$C_4H_3O.C(NH_2)\left\langle{CMe_2 \atop O}\right|$

(215°–220°). Obtained by reducing $C_8H_{10}N_2O_4$, the product of addition of N_2O_3 to furfur-butylene.

Properties.—Colourless liquid, volatile with steam, sol. water.

Salts.—B′HCl aq: crystals, v. sol. water.—$B'_2H_2PtCl_6$: sol. hot. water.

Acetyl derivative $C_8H_9O_2.NHAc$ [153°]; (305°–310°): needles, v. sol. HClAq.

Anhydride C_8H_9NO [142°]. (300°–310°). V.D. 4·77. Formed from amido-furfur-butylene oxide on distilling, or even on keeping. It forms large colourless crystals, and is volatile with steam. It is a tertiary base (Tönnies a. Staub, *B.* 17, 854).

AMIDOGEN. The group NH_2; *v.* Amides, Amido-acids, and Amines.

AMIDO-GLUTARIC ACID *v.* Glutamic Acid.

AMIDO-GLYCOLLIC ACID *v.* Oxy-amido-acetic-acid.

AMIDO-HEMIPIC ACID *v.* Hemipic acid.

AMIDO-HEPTOIC ACID $C_7H_{15}NO_2$ *i.e.* $C_5H_{11}.CH(NH_2).CO_2H$. *a-Amido-œnanthic acid.* From bromo-heptoic acid and alcoholic NH_3 at 100° (Helms, *B.* 8, 1168). Six-sided tables or plates, v. sl. sol. cold water, insol. alcohol.

Salts.—CuA'_2: insoluble powder.—HA′HCl: prisms, v. sol. water or alcohol.

AMIDO-HEXOIC ACID $C_6H_{13}NO_2$.

a-Amido-*n*-hexoic acid *v.* Leucine.

Amido-di-ethyl-acetic acid $CEt_2(NH_2).CO_2H$.

Preparation.—Di-ethyl ketone cyanhydrin, $CEt_2(OH).CN$, obtained by the action of dilute HCN on di-ethyl ketone, is heated with alcoholic NH_3, and the product is saponified by HCl.

Properties.—Thick tables or prisms (from water), v. sol. water, m. sol. alcohol, insol. ether; may be sublimed.

Salts.—AgA′: white plates.—CuA'_2: violet plates.—HA′HCl: thick white prisms (Tiemann a. Friedländer, *B.* 14, 1975).

a-Amido-iso-butyl-acetic acid $Pr.CH_2.CH(NH_2).CO_2H$. S. ·85 at 12°. From iso-valeric aldehyde-ammonia, HCN and HClAq (Limpricht, *A.* 94, 243; Hüfner, *J. pr.* [2] 1, 10).

Properties.—Resembles leucine, but is optically inactive (Mauthner, *H.* 7, 223).

AMIDO-HEXYL ALCOHOL *v.* di-Acetone-alcamine.

AMIDO-HIPPURIC ACID $C_9H_{10}N_2O_3$ *i.e.* $C_6H_4(NH_2).CO.NH.CH_2.CO_2H$.

m-Amido-benzoyl-glycocoll. [194°] (Conrad, *J. pr.* [2] 15, 258). S. ·3 at 20°; S. (alcohol) ·08 at 15°. From *m*-nitro-hippuric acid, ammonium sulphide and H_2S (Schwanert, *A.* 112, 70).

Properties.—Plates or needles. Soluble in alkalis and in acids. Salt.—B′HCl.

Reactions.—1. Boiling HCl forms *m*-amido-benzoic acid and glycocoll.—2. *Urea* forms uramido-hippuric acid $C_{10}H_{11}N_3O_4$ and a small quantity of carboxamido-hippuric acid $C_{19}H_{18}N_4O_7$ (Griess, *J. pr.* [2] 1, 135).

DI-AMIDO-HYDRO-ACRIDINE KETONE, so called, $C_{13}H_{11}N_3O$. [223°]. Formed by reducing the *o*-carboxylic acid of di-nitro-di-phenyl-amine with Sn and HCl. Flat needles or thick prisms, v. sol. hot alcohol, v. sl. sol. ether, benzene, cold water, and light petroleum. Fe_2Cl_6 gives a deep yellow colour, passing into greenish-black; $K_2Cr_2O_7$ gives a red pp.

Salt.—B′HCl: thin colourless needles, sl. sol. cold water.

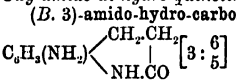
Chloro-derivative $C_{13}H_{10}ClN_3O$. [c. 280°]. Formed by reducing chloro-di-nitro-di-phenyl-amine *o*-carboxylic acid. Colourless crystals, sol. hot water, v. sl. sol. cold water, ether, and benzene (Jourdan, *B.* 18, 1450).

AMIDO-HYDRATROPIC ACID *v.* Amido-phenyl-propionic acid.

DI-AMIDO-HYDRAZO-BENZENE *v.* Hydrazines.

AMIDO-HYDRO-CARBOSTYRIL $C_9H_{10}N_2O$. *Oxy-amido-di-hydro-quinoline.*

(*B.* 3)-amido-hydro-carbostyril

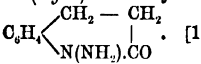


$$C_6H_3(NH_2)\left\langle\begin{matrix}CH_2.CH_2\\ |\\ NH.CO\end{matrix}\right.\left[3:\begin{matrix}6\\5\end{matrix}\right]$$

Di-amido-phenyl-propionic anhydride. Di-amido-hydro-cinnamic anhydride. [211°]. Prepared by reducing di-nitro-phenyl-propionic acid with tin and HCl. It forms colourless needles or prisms, v. sol. hot water, alcohol, and HOAc, insol. CS_2.

Salts.—B′HCl: needles.—$B'_2H_2PtCl_6$: yellow leaflets. *Bromine* forms a mono-bromo-derivative, [210°] and a di-bromo-derivative, [179°], both crystallising in needles (Gabriel a. Zimmermann, *B.* 12, 601).

(*Py.* 4)-**Amido-hydro-carbostyril**



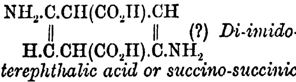
$$C_6H_4\left\langle\begin{matrix}CH_2 - CH_2\\ \quad|\\ N(NH_2).CO\end{matrix}\right. .\quad [143°].$$

From $C_6H_4(NH.NH.SO_3Na)CH_2.CH_2.CO_2H$ (*v.* Hydrazido-phenyl-propionic acid) by addition of HCl (Fischer a. Kuzel, *A.* 221, 282). Crystallised from water. Sol. water, v. sl. sol. alcohol. Does not reduce boiling Fehling's solution, but reduces hot Ag_2O. Salt.–$C_9H_{10}N_2OHCl$.

Reactions.—1. An acid solution is converted by $NaNO_2$ into hydro-carbostyril.—2. With EtI and alcohol at 100° it gives an ethyl derivative  $C_6H_4\left\langle\begin{matrix}CH_2 - CH_2\\ N(NHEt).CO\end{matrix}\right\rangle$. [74°]. This gives a nitrosamine with $NaNO_2$ and HCl.

AMIDO-HYDRO-CINNAMIC ACID *v.* Amido-phenyl-propionic acid.

DI-AMIDO-DI-HYDRO-TERE-PHTHALIC ACID



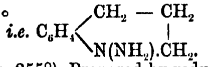
$$\begin{matrix}NH_2.C.CH(CO_2H).CH\\ \| \qquad\qquad \|\\ H.C.CH(CO_2H).C.NH_2\end{matrix}$$

(?) *Di-imido-hexa-hydro-terephthalic acid or succino-succinic-acid-di-imide.*

Ethyl ether $A''Et_2$ [181°]. Obtained by fusing di-oxy-di-hydro-terephthalic ether (succino-succinic ether) with ammonium acetate. Yellow needles; sl. sol. alcohol and ether with a green fluorescence, v. sol. chloroform. By treatment with bromine in H_2SO_4 solution it is converted into di-amido-terephthalic ether. The hydrochloride and sulphate are colourless sparingly soluble salts (Baeyer, *B.* 19, 429).

AMIDO-TETRA-HYDRO-QUINOLINE

$C_9H_{12}N_2$ *i.e.*



$$C_6H_4\left\langle\begin{matrix}CH_2 - CH_2\\ \qquad|\\ N(NH_2).CH_2\end{matrix}\right. .$$

[56°]. (c. 255°). Prepared by reducing the nitrosamine of tetra-hydro-quinoline with zinc dust and HOAc. White crystals.

Salts.—$B'_2H_2SO_4$ 2aq: yellow plates, sl. sol. cold water.—The hydrochloride is v. sol. water.

Reactions.—Reduces salts of Au and Pt, and Fehling's solution. Ppd. HgO forms an azo-quinoline (Hoffmann a. Königs, *B.* 16, 780).

AMIDO HYDRO-QUINONE $C_6H_7NO_2$ *i.e.* $NH_2.C_6H_3(OH)_2$.

Di-methyl derivative $NH_2.C_6H_3(OMe)_2$. [82°]. (270°). Formed by reducing the di-methyl-derivative of nitro-hydroquinone. Pearly plates, sol. hot water, alcohol, benzene, light petroleum and CS_2. Very readily oxidised.

Reactions.—1. $CuSO_4Aq$ gives a greenish-black colour.—Fe_2Cl_6 pps. lustrous greenish plates, which form a red solution in water.—$AgNO_3$ gives a silver mirror. Salts.—×B'HCl: white needles.—×$B'_2H_2PtCl_6$: brown pp.

Acetyl derivative.—$C_6H_3(NHAc)(OMe)_2$. [91°]. Silvery scales; sol. water, alcohol, benzene, light petroleum and CS_2 (Magatti, *B.* 14, 70; *G.* 1881, 352; Mülhäuser, *A.* 207, 254; Baessler, *B.* 17, 2119).

Ethyl derivative $C_6H_3(NH_2)(OEt)(OH)$. From the nitro-compound (Weselsky a. Benedikt, *M.* 2, 370).—B'HCl.

Di-amido-hydroquinone $C_6H_2(OH)_2(NH_2)_2$. Formed by reduction of di-nitro-hydroquinone or its di-acetyl derivative with tin and HCl. Owing to its easy oxidisability the base was not isolated in the free state. $B''H_2Cl_2$.—Colourless needles, v. e. sol. water, sl. sol. conc. HCl.

Di-acetyl derivative $C_6H_2(OH)_2(NHAc)_2$. [c. 240°]. Colourless needles. Is oxidised to di-acetyl-di-amido-quinone $C_6H_2O_2(NHAc)_2$.

Tetra-acetyl derivative $C_6H_2(OAc)_2(NHAc)_2$. [216°]; colourless needles or plates; v. sol. alcohol and acetic acid, sl. sol. water and ether. Dissolves in dilute alkalis, the solution becomes oxidised on exposure to the air and deposits yellow needles of the above-mentioned di-acetyl-di-amido-quinone (Nietzki a. Preusser, *B.* 19, 2247).

Di-methyl-derivative $C_6H_2(NH_2)_2(OMe)_2$. The hydrochloride of this body is formed by reducing the corresponding nitro compound. It crystallises in needles, [169°] (Kariof, *B.* 13, 1676).

Di-methyl-di-amido-hydroquinone (*q. v.*) is isomeric with this body.

DI-AMIDO-DI-IMIDO-BENZENE $C_6H_2(NH_2)_2(NH)_2$ [1:2:4:5]. Small brown needles. Formed by oxidation of solutions of salts of tetra-amido-benzene with Fe_2Cl_6, &c.

Salts.—$B''H_2Cl_2$: glittering brown needles, sparingly soluble in water with a bluish-violet colour.—$B''(HNO_3)_2$: small green needles (Nietzki a. Hagenbach, *B.* 20, 335).

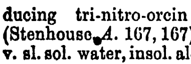
AMIDO-IMIDO-METHANE *v.* FORMAMIDINE.

AMIDO-DI-IMIDO-(α)-NAPHTHOL $C_{10}H_9N_3O$ *i.e.*

$C_{10}H_4(NH_2)(OH)\left\langle\begin{matrix}NH\\|\\NH\end{matrix}\right.$

(?). Prepared by the reduction of tri-nitro-(α)-naphthol with tin and HCl. Brown scales, insol. water and ether. Salts.—B'HCl: lustrous green scales, sl. sol. cold water.—$B'_2H_2PtCl_6$ (Diehl a. Merz, *B.* 11, 1663).

AMIDO-DI-IMIDO-ORCIN $C_7H_9N_3O_2$ 2aq *i.e.*



$C_6Me(NH_2)(OH)_2\left\langle\begin{matrix}NH\\|\\NH\end{matrix}\right.$

(?). Prepared by reducing tri-nitro-orcin with sodium-amalgam (Stenhouse, *A.* 167, 167). Lustrous green needles, v. sl. sol. water, insol. alcohol, ether, and benzene. NaOHAq forms a deep blue solution. Reduced by further action of sodium-amalgam to tri-amido-orcin. Salts.—B'HCl aq: brownish-red needles; sol. water but ppd. by HCl.—$B'_2H_2SO_4$ 2aq: purple laminæ.

AMIDO-DI-IMIDO-PHENOL, so called. $C_6H_7N_3O$ *i.e.*

$C_6H_2(NH_2)_2\left\langle\begin{matrix}NH\\|\\O\end{matrix}\right.$ $\left[2:6:\begin{matrix}1\\4\end{matrix}\right]$.

Di-amido-quinone-imide (Hepp, *A.* 215, 351). The hydrochloride, B'HCl, separates as brown needles with [illegible] when Fe_2Cl_6 is added to a conc. aqueous solution of the hydrochloride of tri-amido-phenol (Heintzel, *Z.* 1867, 342). It is decomposed by alkalis and by hot water; hot dilute HCl changes it into colourless needles of the hydrochloride of oxy-amido-quinone-imide (or di-amido-quinone) $C_6H_6N_2O_2HCl$, while H_2SO_4 forms a corresponding sulphate crystallising in plates.

AMIDO-IMIDO-DI-PHENYL SULPHIDE $C_{12}H_{10}N_2S$ *i.e.*

$HN\left\langle\begin{matrix}C_6H_4\\C_6H_3(NH_2)\end{matrix}\right\rangle S$.

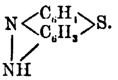
Amido-thio-di-phenyl-imide; Amido-sulphido-di-phenyl-imide.

Formation.—1. By reduction of nitro-imido-di-phenyl-sulphoxide,

$HN\left\langle\begin{matrix}C_6H_4\\C_6H_3(NH_2)\end{matrix}\right\rangle SO$.—

2. By heating *p*-amido-di-phenyl-amine with sulphur (Bernthsen, *B.* 17, 2858; *A.* 230, 101). White satiny plates (from water); m. sol. hot water, v. sol. alcohol and ether. Turns grey in moist air. Fe_2Cl_6 converts it into the following body:

Imido-imido-di-phenyl sulphide $C_{12}H_8N_2S$ *i.e.*



$\begin{matrix}N\left\langle\begin{matrix}C_6H_4\\C_6H_3\end{matrix}\right\rangle S.\\|\ \ /\\NH\end{matrix}$

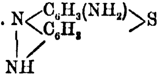
Small brown crystals, v. sol. alcohol, sl. sol. water and ether. Its salts dye silk greyish-violet. It is easily reduced to the preceding body. Salts.—B'HCl ½aq.—$B'_2H_2ZnCl_4$: brown needles or prisms.

Di-amido-imido-di-phenyl sulphide $C_{12}H_{11}N_3S$ *i.e.*

$HN\left\langle\begin{matrix}C_6H_3(NH_2)\\C_6H_3(NH_2)\end{matrix}\right\rangle S$.

Formed by reducing (α)-di-nitro-imido-di-phenyl sulphoxide with tin and HCl, or Lauth's violet with ammonium sulphide (Bernthsen, *B.* 17, 614). Yellow needles or plates; sl. sol. water and ether. The sulphate is sl. sol. water.

Amido-imido-imido-di-phenyl-sulphide $C_{12}H_9N_3S$ *i.e.*



$\begin{matrix}N\left\langle\begin{matrix}C_6H_3(NH_2)\\C_6H_3\end{matrix}\right\rangle S.\\|\ \ /\\NH\end{matrix}$

Lauth's Violet.

Formation.—1. By treating a solution of *p*-phenylene diamine hydrochloride with H_2S and Fe_2Cl_6 successively (Lauth, *C. R.* 82, 1441; Koch, *B.* 12, 592, 2069).—2. By action of Fe_2Cl_6 on the preceding body (B.). Its alcoholic solution has a violet colour with reddish-brown fluorescence. Its solution in excess of HCl is blue; in H_2SO_4, green changing to blue and then to violet. Long heating with MeI converts it into the methylo-iodide of penta-methyl-di-amido-imido-di-phenyl sulphide identical with that formed in the same way from methylene blue. Salt.—B'HCl: green crystals, sl. sol. cold water.

An isomeride (*Bernthsen's Violet*) is formed by reducing (β)-di-nitro-imido-di-phenyl sulphoxide and then oxidising the leuco-base with Fe_2Cl_6. Its hydrochloride B'2HCl, forms dark needles, which dye reddish-violet. H_2SO_4 forms a violet solution.

AMIDO-DI-IMIDO RESORCIN $C_6H_7N_3O_2$ aq or

$C_6H(OH)_2(NH_2)\left\langle\begin{matrix}NH\\ |\\ NH\end{matrix}\right.$ (?). From tri-amido-resorcin hydrochloride and Fe_2Cl_6. Lustrous green needles, v. sl. sol. water, insol. alcohol or ether: KOHAq forms a blue solution. Dilute HCl at 170° forms tri-oxy-quinone.

Salt.—B'HCl: red needles, ppd. by HCl (Schreder, *A.* 158, 250; Diehl a. Merz, *B.* 11, 1229).

AMIDO-INDIGO $C_{16}H_{12}N_4O_2$ *i.e.* $C_{16}H_8(NH_2)_2N_2O_2$. Prepared by reducing nitro-indigo with acetic acid and powdered zinc (Baeyer, *B.* 12, 1317). Dark violet pp., v. sl. sol. alcohol, ether and chloroform. Forms blue solutions in dilute acids.

AMIDO-ISATIN, so called, *v.* ISATINIMIDE.

AMIDO-LACTIC ACID *v.* OXY-AMIDO-PROPIONIC ACID.

AMIDO-MALEÏC ACID $C_4H_5NO_4$ *i.e.* $CO_2H.CH:C(NH_2).CO_2H$. [182°]. Easily soluble crystals. Prepared by saponification of the amides.—$A''Ag_2$: voluminous pp., explosive.

Di-ethyl ether Et_2A''. [100°]. Colourless prisms. Sol. alcohol and ether, insol. water. Prepared by the action of alcoholic NH_3 (2 mols.) on chloro-maleïc ether (1 mol.).

Amido-maleamic-ethyl ether

$C_2H(NH_2)\left\langle\begin{matrix}CO.NH_2\\ CO_2Et\end{matrix}\right.$. [62°]. Long white prisms. V. sol. alcohol and ether, insol. cold water. Prepared by the action of alcoholic NH_3 (3 mols.) on chloro-maleic ether (1 mol.).

Diamide

$C_2H(NH_2)\left\langle\begin{matrix}CO.NH_2\\ CO.NH_2\end{matrix}\right.$. [122°]. Colourless plates. Sol. alcohol, ether, and hot water. Prepared by the action of an excess of strong alcoholic NH_3 on chloro-maleïc ether (Claus a. Voeller, *B.* 14, 150).

AMIDO-MALONIC ACID $C_3H_5NO_4$ *i.e.* $CH(NH_2)(CO_2H)_2$. Obtained from nitroso-malonic acid by reducing with sodium-amalgam (Baeyer, *A.* 131, 295). Prisms (from water) or needles (by ppg. with alcohol). When heated alone, or in aqueous solution, it splits up into CO_2 and glycocoll. Iodine oxidises it, in aqueous solution, forming mesoxalic acid.

Salt.—$Pb(C_3H_4NO_4)_2$: crystalline pp.

Amide $CH(NH_2)(CO.NH_2)_2$. [182°]. Formed by heating chloro-malonic ether with alcoholic NH_3. Prisms, sol. hot water (Conrad a. Guthzeit, *B.* 15, 607).

AMIDO-MESITOL $C_9H_{13}NO$ *i.e.* $C_6HMe_3(NH_2)(OH)$ [1:3:5:2:4]. A very oxidisable body formed by reduction of nitro-mesitol.—B'HCl: needles (Knecht, *B.* 15, 1376).

AMIDO-MESITYLENE *v.* MESIDINE.

Di-amido-mesitylene $C_9H_{14}N_2$ *i.e.* $C_6HMe_3(NH_2)_2$. [90°]. From di- or tri-nitro-mesitylene with tin and HCl. Long slender needles (from water), or large monoclinic crystals (from ether). Sublimes in needles. V. sol. alcohol or ether, m. sol. hot water. CrO_3 oxidises it to oxy-iso-xyloquinone, $C_6HMe_2(OH)O_2$.

Salts.—$B''2HCl$: square tables (from water), ppd. by HCl.—$B''H_2C_2O_4$: hard grains (from water).—$B''H_2SO_4$: broad laminæ (from water).

Di-acetyl derivative, [above 360°]; v. sl. sol. water or cold alcohol (Fittig, *A.* 141, 134; 180, 27; Ladenburg, *A.* 179, 176).

AMIDO-MESITYLENIC ACID $C_9H_{11}NO_2$.

o-Amido-mesitylenic acid $C_6H_2Me_2(NH_2).CO_2H$ [1:3:4:5]. [187°] (Schmitz, *A.* 193, 171). [190°] (Jacobsen, *B.* 11, 2055). From the nitro acid with tin and HCl. Long needles (from alcohol). Splits up when heated with lime into CO_2 and (1, 3, 4)-xylidine.

[illegible]**-Amido-mesitylenic acid** $C_6H_2Me_2(NH_2)CO_2H$ [1:3:2:5]. [235°]. From the nitro acid. Long needles (from alcohol). Sl. sol. water, v. sol. hot alcohol. Gives (1, 3, 2)-xylidine when heated with lime.

Salt.—B'HCl: long needles (Fittig a. Brückner, *A.* 147, 50; Jacobsen, *B.* 12, 608).

AMIDO - METHENYL - AMIDO - PHENYL MERCAPTAN $C_7H_6N_2S$ *i.e.*

$C_6H_4\left\langle\begin{matrix}N\\ S\end{matrix}\right\rangle C.NH_2$. [129°]. Prepared by heating chloro-methenyl-amido-phenyl mercaptan with alcoholic NH_3 at 160°. Nacreous laminæ. Fusion with potash produces amido-phenyl mercaptan.

Salt.—It is a weak base, and has a crystalline platinochloride, $B'_2H_2PtCl_6$ (Hofmann, *B.* 12, 1129; 13, 11).

AMIDO-METHOXY COMPOUNDS *v.* Methyl derivatives of OXY-AMIDO COMPOUNDS.

AMIDO-DI-METHYL-ACETIC ACID *v.* AMIDO-*iso*-BUTYRIC ACID.

DI-AMIDO-TETRA-METHYL-DI-AMIDO-DIPHENYL *v.* *Tetra*-METHYL-*tetra*-AMIDO-DIPHENYL. And, in general, amido-methyl-amido compounds are described as methyl-(di)-amido compounds.

AMIDO-DI-METHYL-ANILINE *v.* *Di*-METHYL-PHENYLENE DIAMINE.

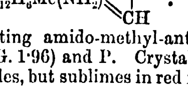
AMIDO-METHYL-ANTHRACENE DI-HYDRIDE $C_{15}H_{15}N$ *i.e.* $C_{14}H_{10}Me.NH_2$. [79°]. Prepared by heating amido-methyl-anthraquinone with HI and P at 150°. Glistening laminæ, which begin to sublime at 130° and are sol. alcohol, ether, chloroform, benzene, glacial acetic acid, and CS_2, but v. sl. sol. water.

Reactions.—1. *Nitrous acid* gives a green colour, and on adding NH_3, a red pp.—2. *Arsenic acid* gives a brownish-red mass after fusion. **Salt.**—B'HCl [245°]: glistening needles.

Acetyl derivative $C_{15}H_{14}AcN$. [198°]. White needles, sol. alcohol and ether (Roemer, *B.* 16, 1631).

AMIDO-METHYL-ANTHRANOL

$C_{15}H_{13}NO$ *i.e.*



$C_{12}H_6Me(NH_2)\left\langle\begin{matrix}C.OH\\ \|\\ CH\end{matrix}\right.$. [183°]. Prepared by heating amido-methyl-anthraquinone with HI (S.G. 1·96) and P. Crystallises in nearly white needles, but sublimes in red needles. Sol. alcohol, ether, benzene, and glacial acetic acid, v. sl. sol. water.

Reactions.—1. H_2SO_4 gives a yellow solution, becoming purple-red on warming.—2. HNO_3 gives a violet colour, turning red.—3. *Air* reconverts it, in alkaline solution, into amido-methyl-anthraquinone.

Di-acetyl derivative $C_{15}H_{11}Ac_2NO$. [170°]. Thick white needles; its alcoholic solution exhibits blue fluorescence (Roemer a. Link, 16, 703).

AMIDO-METHYL-ANTHRAQUINONE $C_{15}H_{11}NO_2$ *i.e.* $C_{14}H_6O_2(CH_3)(NH_2)$. [202°]. Prepared by reduction of nitro-methyl-anthraquinone. Long dark red needles. V. sol. alcohol, ether, benzene, acetic acid, and chloroform, v. sl. sol. water.

Acetyl derivative $C_{14}H_8O_2(CH_3)NHAc$. [177°]. Small light-red needles, sol. alcohol and glacial acetic acid (Römer a. Link, *B.* 16, 698).

AMIDO-METHYL BENZENE *v.* TOLUIDINE and BENZYLAMINE.

Amido-di-methyl-benzene *v.* XYLIDINE.

Amido-tri-methyl-benzene *v.* MESIDINE and ψ-CUMIDINE.

Amido-tetra-methyl-benzene *v.* DURIDINE.

Amido-penta-methyl-benzene *v.* *Penta*-METHYL-PHENYL-AMINE.

DI-AMIDO-TETRA-METHYL-BENZIDINE *v.* *Tetra*-METHYL-*tetra*-AMIDO-*di*-PHENYL.

AMIDO-METHYL-BENZOIC ACID *v.* AMIDO-TOLUIC ACID.

Amido-di-methyl-benzoic acid *v.* AMIDO-MESITYLENIC ACID.

Di-amido-tri-methyl-benzoic acid $C_{10}H_{14}N_2O_2$ *i.e.* $C_6Me_3(NH_2)_2CO_2H$ [6:4:3:5:2:1]. *Di-amido-durylic acid.* [221°]. Formed by reducing the di-nitro compound with zinc dust and dilute HOAc. Colourless silky needles, sol. hot water and hot alcohol, v. sl. sol. ether. Fe_2Cl_6 oxidises it to pseudo-cumo-quinone carboxylic acid (Nef, *B.* 18, 3496; *A.* 237, 1).

Acetyl-derivative [275°].

AMIDO-TRI-METHYL-BUTYL-LACTIC ACID *v.* OXY-AMIDO-HEPTOIC ACID.

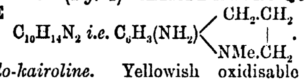
m-**AMIDO-**α**-METHYL-CINNAMIC ALDEHYDE** $C_{10}H_{11}NO$ *i.e.* $C_6H_4(NH_2).CH{:}CMe.CHO$ [60°]. Got by reducing the nitro compound with $FeSO_4$ and NH_3. Yellowish crystals; dissolves in aqueous acids, and reduces ammoniacal $AgNO_3$.

Phenyl hydrazide $C_6H_4(NH_2).CH{:}CMe.CH{:}N_2HPh$; [157°]: needles.

Acetyl derivative $C_6H_4(NHAc).CH{:}CMe.CHO$; [120°]: short thick prisms (Miller a. Kinkerlin, *B.* 19, 1248).

AMIDO-(*B.* 2-*Py.* 2)-DI-METHYL-(*Py.* 3)-ETHYL-QUINOLINE $C_{13}H_{16}N_2$ *i.e.* $C_9H_3N(NH_2)Me_2Et$. [149°]. Plates, monoclinic tables, prisms or flat needles. Formed by reduction of the nitro-derivative with $SnCl_2$. Salts.—$B'HCl$; very soluble colourless crystals. The nitrate and sulphate are also easily soluble in water (Harz, *B.* 18, 3392).

AMIDO-(*Py.* 4)-METHYL-HYDRO-QUINOLINE



$$C_{10}H_{14}N_2 \text{ i.e. } C_6H_3(NH_2)\Big\langle\begin{matrix}CH_2.CH_2\\ |\\ NMe.CH_2\end{matrix}.$$

Amido-kairoline. Yellowish oxidisable oil. Formed by reduction of nitro-kairoline [94°] with $SnCl_2$. By nitrous acid it is converted into a compound $C_{10}H_{13}N_3O$, [144°] when dry, which crystallises with 5aq in splendid red needles, and dissolves in dilute acids with a deep red colour.

Salts.—The acid tartrate forms sparingly soluble crystals. $B''H_2Cl_2PtCl_4$ (Feer a. Koenigs, *B.* 18, 2391).

AMIDO-DI-METHYL-HYDROQUINONE *v.* *di-methyl*-AMIDO-HYDROQUINONE.

AMIDO-TRI-METHYL-PHENYL-ACETAMIDINE *v.* AMIDO-ψ-CUMYLENE-ACETAMIDINE.

AMIDO-DI-METHYL-PHENYL-ACETIC ANHYDRIDE *v.* *Di*-METHYL-OXINDOLE.

AMIDO-METHYL-PROPYL-BENZENE *v.* CYMIDINE.

(*B.* 4)-AMIDO-(*Py.* 3)-METHYL-QUINOLINE $C_{10}H_{10}N_2$ *i.e.* $C_9H_5(CH_3)(NH_2)N$. *o-Amido-quinaldine.* [56°]. Formed by reduction of (*B.* 4)-nitro-(*Py.* 3)-methyl-quinoline. Long prisms. V. sol. alcohol, ether, and hot ligroine, sparingly in water.—$B'HCl$: yellow needles (Doebner a. Miller, *B.* 17, 1701).

(*B.* 1 or 3)-**Amido-(*Py.* 3)-methyl-quinoline** $C_{10}H_{10}N_2aq$ *i.e.* $C_9H_5(CH_3)(NH_2)N$ *m-Amido-quinaldine* [105°] when [illegible]. Formed by reduction of (*B.* 1 or 3)-nitro-(*Py.* 3)-methyl-quinoline. Colourless crystals (+ H_2O). V. sol. hot water, alcohol, and benzene, sparingly in ether. $B'HCl$: red needles (Doebner a. Miller, *B.* 17, 1702).

Amido-(*B.* 2, 4-*Py.* 3)-tri-methyl-quinoline $C_{12}H_{12}N(NH_2)$. Formed by reducing nitro-tri-methyl-quinoline with $SnCl_2$. Yellowish plates (from alcohol) (Panajotow, *B.* 20, 36).

Sulphonic acid $C_{12}H_{11}(SO_3H)(NH_2).N$. Small yellow needles. BaA'_2 3aq: silky needles, sl. sol. cold water.

AMIDO-METHYL-TOLUIDINE *v.* METHYL-TOLYLENE DIAMINE.

AMIDO-β-METHYL UMBELLIFERON

$$C_{10}H_9NO_3 \text{ i.e. } C_6H_2(NH_2)(OH)\Big\langle\begin{matrix}CMe{:}CH\\ |\\ O\ .\ CO\end{matrix} \quad [247°].$$

From nitro-β-methyl-umbelliferon. Needles, sparingly soluble in the usual menstrua. Fe_2Cl_6 gives an intense green colouration with the alcoholic solution.

Salt.—$B'_2H_2SO_4$ 2aq: sparingly soluble pp. (Pechmann a. Cohen, *B.* 17, 2137).

AMIDO-METHYL-URACIL *v.* URAMIDO-CROTONIC ACID.

AMIDO-NAPHTHALENE *v.* NAPHTHYLAMINE.

Di-amido-naphthalene *v.* NAPHTHYLENE DIAMINE.

Tri-amido-naphthalene $C_{10}H_{11}N_3$ *i.e.* $C_{10}H_5(NH_2)_3$. The *hydriodide*, $B'''3HI$, is formed from (β)-tri-nitro-naphthalene [218°], by reducing it (1 g.) with I (20 g.), P (4 g.) and water; it forms white needles; at 70° it becomes $B'''2HI$. The *sulphate*, $B'''H_2SO_4$ forms silky needles. The free base is very unstable.

Benzoyl derivative $C_{17}H_{15}N_3O$ *i.e.* $C_{10}H_5(NH_2)_2(NHBz)$[2:4':1]. From benzoyl-di-nitro-naphthylamine.

Salts.—$B'''HCl$: needles.—$B'''H_2SO_4$: needles (Lautemann a. Aguiar, *Bl.* [2] 3, 263; Hübner a. Ebell, *A.* 208, 324).

Tetra-amido-naphthalene $C_{10}H_{12}N_4$ *i.e.* $C_{10}H_4(NH_2)_4$. The hydriodide $B''''4HI$, formed by reducing (β)-tetra-nitro-naphthalene [200°] with P, I, and water, crystallises in yellowish laminæ, sol. water and alcohol (L. a. A.).

AMIDO-NAPHTHALENE SULPHONIC ACID *v.* NAPHTHYLAMINE SULPHONIC ACID.

AMIDO-(β)-NAPHTHO-HYDROQUINONE $C_{10}H_9NO_2$ *i.e.* $C_{10}H_5(NH_2)(OH)_2$. *Amido-di-oxy-naphthalene.* The *hydrochloride*, $B'HCl$, is got by reducing nitro-(β)-naphthohydroquinone with tin and HCl (Groves, *C. J.* 45, 300). It is rapidly oxidised by air.

AMIDO-NAPHTHOIC ACID $C_{11}H_9NO_2$ *i.e.* $C_{10}H_6(NH_2).CO_2H$.

Amido-(α)-naphthoic acid. [212°]. From nitro-(α)-naphthoic acid, [230°], by reducing with $FeSO_4$ and NH_3. Colourless needles; may be sublimed; sol. alcohol, v. sl. sol. ether (Ekstrand, *B.* 18, 78).

Amido-(β)-naphthoic acid. [211°]. Formed by reducing nitro-(β)-naphthoic acid [269°], with $FeSO_4$ and NH_3. Slender colourless needles (Ekstrand, *B.* 18, 1206).

Amido-(β)-naphthoic acid. [219°]. From nitro-(β)-naphthoic acid [289°]. Slender needles. Salts.—×HA'HCl: small prisms, v. sol. water.—×HA'HNO$_3$: large thin laminæ.—×$(HA')_2H_2SO_4$: small prismatic needles (E.).

Amido-(β)-naphthoic acid. [232°]. From nitro-(β)-naphthoic acid [293°]. Small trimetric tables; sol. alcohol and boiling water. Salts.—CaA'$_2$ 4aq: long violet needles.—HA'HNO$_3$: large needles.—$(HA')_2H_2SO_4$: needles (E.).

peri-**Amido-naphthoic acid** $C_{10}H_6(NH_2)CO_2H$ [α_1 α'_1].

Preparation.—The crude product of the nitration of (α)-naphthoic acid is reduced with $FeSO_4$. The solution is boiled with HCl and, on cooling, the lactam of the peri-acid, [178°], crystallises out in yellow needles, whilst the hydrochloride of the isomeric acid remains in solution.

By diazotisation, treatment with cuprous cyanide, and saponification of the nitrile, naphthalic acid is formed (Bamberger a. Philip, *B.* 20, 242). This experiment determines the constitution of acenaphthene (*q.v.*) which may be oxidised to naphthalic acid.

Lactam $C_{11}H_7NO$

i.e. $C_{10}H_6\left<\begin{matrix}CO\\NH\end{matrix}\right>$. [179°].

Formed by reducing nitro-(α)-naphthoic acid [215°]. Needles (by sublimation); sol. hot alcohol, sl. sol. water and ether. It is an indifferent substance insoluble in alkaline carbonates, but soluble in hot aqueous NaOH with formation of the acid (Ekstrand, *B.* 18, 75; 19, 1137; compare Rakowsky, *B.* 5, 1020).

Acetyl derivative $C_{11}H_6AcNO$. [125°]. Long hair-like needles (from alcohol).

AMIDO-NAPHTHOL $C_{10}H_9NO$.

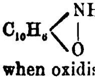
(α)-**Amido-(α)-naphthol** $C_{10}H_6(OH)(NH_2)$ [1:4]. Formed by reducing nitro-(α)-naphthol [164°] (Liebermann, *A.* 183, 247) or *p*-sulpho-benzene-azo-(α)-naphthol (Liebermann, *B.* 14, 1796).

The free base is unstable; its salts produce (α)-naphthoquinone when oxidised.

B'HCl: white needles; converted by bleaching powder into $C_{20}H_{10}N_3Cl$ or $C_{20}H_{12}N_3Cl$ which separates from HOAcAq in needles [85°], and explodes at 130° (Hirsch, *B.* 13, 1910).

(β)-**Amido-(α)-naphthol** $C_{10}H_6(OH)(NH_2)$ [1:2]. Formed by reducing nitro-(α)-naphthol [128°], or nitroso-(α)-naphthol (L.).

The free base is unstable; in presence of alkalis, air forms violet naphthoquinone-imide,



$C_{10}H_6\left<\begin{matrix}NH\\|\\O\end{matrix}\right.$. Its salts give (β)-naphthoquinone when oxidised. B'HCl: white laminæ.—B'$C_6H_2(NO_2)_3OH$.

(α)-**Amido-(β)-naphthol** $C_{10}H_6(OH)(NH_2)$. Formed by reducing nitro-(β)-naphthol [103°] (Jacobsen, *B.* 14, 806; *A.* 211, 48) or nitroso-(β)-naphthol (Groves, *C. J.* 45, 296).

Preparation.—(β)-naphthol orange is heated with HClAq and $SnCl_2$ in slight excess over that required by the equation:

$$HO.C_{10}H_6.N_2.C_6H_4.SO_3Na + 2SnCl_2 + 6HCl = HO.C_{10}H_6.NH_2HCl + NH_2.C_6H_4.SO_3H + 2SnCl_4 + NaCl,$$

Amido-(β)-naphthol hydrochloride crystallises on cooling, and is freed from sulphanilic acid by washing with NaOHAq (Groves, *C. J.* 45, 291).

Properties.—Colourless scales, v. sl. sol. water, readily oxidised by air. Its ethereal solution fluoresces violet. *Chromic mixture* oxidises it to (β)-naphthoquinone.

Salt.—B'HCl: white needles.

Benzoyl derivative.—$C_{10}H_6(NHBz)OH$. [245°]. Small colourless plates, soluble in alkalis. Formed by reduction of the benzoyl-derivative of (α)-nitro-(β)-naphthol, the benzoyl group wandering from the hydroxyl to the amidogen; this probably takes place by the intermediate formation of benzenyl-amido-naphthol

$C_{10}H_6\left<\begin{matrix}N\\O\end{matrix}\right>C.C_6H_5$ since this body occurs in the reduction product.

Acetyl derivative.—$C_{10}H_6(NHAc)OH$. [225°]. Plates. Formed by reduction of the acetyl derivative of (α)-nitro-(β)-naphthol, the same isomeric change taking place as in the preceding case (Böttcher, *B.* 16, 1935).

Di-amido-(α)-naphthol $C_{10}H_{10}N_2O$ *i.e.* $C_{10}H_5(OH)(NH_2)_2$. From di-nitro-(α)-naphthol [138°] (Griess a. Martius, *A.* 134, 376). Its aqueous solution is turned red by Fe_2Cl_6, amido-naphthoquinone imide (*q. v.*) being formed.

Salts. (Graebe a. Ludwig, *A.* 154, 307).—B''H$_2$SnCl$_4$: monoclinic prisms, $a:b:c$ = 1·184:1:1·487, β = 72° 33'.—B''H$_2$SnCl$_4$ 4aq.—B''H$_2$SO$_4$ 2aq.

Tri-amido-(α)-naphthol $C_{10}H_{11}N_3O$ *i.e.* $C_{10}H_4(OH)(NH_2)_3$. From tri-nitro-(α)-naphthol (Diehl a. Merz, *B.* 11, 1665; Ekstrand, *B.* 11, 161).

B'''H$_2$SO$_4$aq: scales.—B'''3HCl aq: needles.

AMIDO-(β)-NAPHTHOL SULPHONIC ACID. $C_{10}H_5(OH)(NH_2).SO_3H$. From nitroso-(β)-naphthol sulphonic acid (*q. v.*) with tin and HCl (Meldola, *C. J.* 39, 47). Long white needles, v. sol. water, turned brown by air. Gives phthalic acid with HNO$_3$Aq. The acid obtained by reducing *m*-carboxy-benzene-azo-sulpho-(β)-naphthol appears to be an isomeride (Griess, *B.* 14, 2032).

Di-Amido-(α)-naphthol-sulphonic acid $C_{10}H_4(OH)(NH_2)_2SO_3H$ [1:2:4:β']. Prepared by reducing naphthol yellow S. Laminæ; gives di-imido-(α)-naphthol sulphonic acid when oxidised (Lauterbach, *B.* 14, 2029).

Amido-(β)-naphthol di-sulphonic acid $C_{10}H_4(OH)(NH_2)(SO_3H)_2$3aq. From *m*-carboxy-benzene-azo-sulpho-(β)-naphthol by reduction. Laminæ, v. sol. water (Griess, *B.* 14, 2042).

AMIDO-NAPHTHOQUINONE $C_{10}H_7NO_2$ *i.e.* $C_{10}H_5(NH_2)O_2$. *Oxy-naphtho-quinone imide. Oximido-naphthol.* Orange needles, formed by boiling amido-naphthoquinone imide with water (Martius a. Griess, *A.* 134, 377; Graebe a. Ludwig, *A.* 154, 307). Sl. sol. boiling water, v. sol. alcohol, insol. ether. Converted by boiling *acids* or *alkalis* into oxy-naphthoquinone. *Aniline*, when heated with it in acetic acid solution, forms naphthoquinone di-anilide.

Its dihydride is described as AMIDO-NAPHTHO-HYDROQUINONE.

AMIDO NAPHTHOQUINONE-IMIDE

$C_{10}H_8N_2O$ *i.e.* $C_{10}H_5(NH_2)\langle\begin{smallmatrix}NH\\|\\O\end{smallmatrix}$.

Di-imido-naphthol. From di-amido-(α)-naphthol and Fe_2Cl_6Aq (Graebe a. Ludwig, *A.* 154, 307). Minute needles, v. sl. sol. cold water, v. sol. alcohol. Boiling alkalis and dilute acids at 120° convert it into oxy-naphthoquinone. Reducing agents produce di-amido-(α)-naphthol. Aniline heated with its hydrochloride forms naphthoquinone di-anilide. Salt.—$B'HCl$: dark red monoclinic prisms with green lustre $a:b:c = 2{\cdot}967:1:2{\cdot}396$ $\beta = 74°\ 28'$ — $B'_2H_2PtCl_6$. — $B'H_2CrO_4$: S. ·13 at 12°.—$B'H_2SO_4$.

Bromine-water added to an aqueous solution of amido-naphthoquinone imide produces two derivatives (Kronfeld, *B.* 17, 715):

1. $C_9H_4Br_2O_2$ [173°]: white plates, sol. alcohol, benzene, HNO_3 (S.G. 1·4), and $CHCl_3$.

2. $C_{10}H_6Br_3NO_3$ *i.e.* $CBr_3.CO.C_6H_4.C(NH).CO_2H$ [213°]: white needles, sol. alcohol, benzene and HNO_3 (S.G. 1·4), insol. chloroform. It is split up by cold *alkalis* into phthalimide and bromoform. When heated alone or better with H_2SO_4 at 140° it gives CO_2, Br_2 and an acid $C_9H_6Br_2NO$ [237°]. This loses HBr when boiled for a long time with alkalis. When heated with H_2SO_4 it gives phthalic acid.

AMIDO - NAPHTHOQUINONE SULPHONIC ACID $C_{10}H_8N_2SO_4$. Minute coppery needles, formed by oxidising di-amido-naphthol sulphonic acid.

DI - AMIDO - DINAPHTHYL $C_{20}H_{16}N_2$. *Dinaphthyline.* $C_{10}H_6(NH_2).C_{10}H_6(NH_2)$. [273°]. Colourless plates (from benzene). Formed together with a smaller quantity of the isomeric naphthidine by warming (αα)-hydrazonaphthalene with two mols. of dilute HCl at 70°–80°; a clear solution is formed from which the naphthidine is ppd. as its sparingly soluble hydrochloride by adding an excess of HCl, the easily soluble hydrochloride of dinaphthyline remaining in solution.

Reactions.—By diazotising and boiling with alcohol it is converted into (αα)-dinaphthyl [154°]. By boiling with acids NH_3 is easily split off, giving imido-dinaphthyl  $\begin{smallmatrix}C_{10}H_6\\|\\C_{10}H_6\end{smallmatrix}\rangle NH$. By CrO_3 it is oxidised to phthalic acid.

Salts. — $B''H_2Cl_2{}^{\times}$: easily soluble. — $B''H_2Cl_2PtCl_4$: sparingly soluble yellow plates (Nietzki a. Goll, *B.* 18, 5254).

Di-amido-dinaphthyl (*naphthidine*). Probably [4 : 1] $C_{10}H_6(NH_2).C_{10}H_6(NH_2)$ [1 : 4]. [198°]. Silvery plates or colourless tables. Soluble in alcohol and benzene. Formed, together with its isomeride dinaphthyline, in small quantity by heating (αα)-hydrazonaphthalene with HCl, and in large quantity by reduction of (αα)-azonaphthalene with $SnCl_2$ and HCl.

Preparation.—One pt. of azonaphthalene is dissolved in 45 pts. of hot acetic acid, and a solution of $SnCl_2$ (1 pt.) in 2 pts. of HCl and 2–3 pts. of water is added in sufficient quantity to decolourise it; on adding an excess of HCl the sparingly soluble hydrochloride of naphthidine is ppd.

Reactions.—Fe_2Cl_6, CrO_3, Cl_2, &c., produce a carmine red colouration or pp. with solutions of naphthidine salts. By heating with CrO_3 it is oxidised to (α)-naphthoquinone and finally to phthalic acid. Its diazo-compound yields violet colouring-matters with the sulphonic acids of (β)-naphthol. By boiling the diazo-compound with alcohol it yields (αα)-dinaphthyl [154°].

Salts.—$B''H_2Cl_2$: sparingly soluble colourless silvery plates.—$B''H_2Cl_2PtCl_4$.—$B''H_2SO_4$: very sparingly soluble glistening plates.

Di-acetyl-derivative $C_{20}H_{12}(NHAc)_2$ [over 300°]; nearly insoluble in ordinary solvents (Nietzki a. Goll, *B.* 18, 3254).

Di - amido - (αα) - dinaphthyl $C_{20}H_{12}(NH_2)_2$. Obtained by reduction of di-nitro-dinaphthyl with zinc dust and HCl. It is readily oxidised to the di-imido-compound  $C_{20}H_{12}\langle\begin{smallmatrix}NH\\|\\NH\end{smallmatrix}$, so that it cannot be diazotised. $B''H_2Cl_2$: easily soluble colourless needles. The bichromate pps. in brown crystals.

Di-acetyl-derivative $C_{20}H_{12}(NHAc)_2$. [Above 300°]. Colourless needles; insoluble in all solvents (Julius, *B.* 19, 2551).

Twenty-eight di-amido-(αα)-di-naphthyls are indicated by theory.

Tetra - amido - iso - di - naphthyl $C_{20}H_{10}(NH_2)_4$. [164°–167°]. From tetra-nitro-iso-di-naphthyl. Grey powder, sl. sol. alcohol, m. sol. toluene (Staub a. Watson Smith, *C. J.* 47, 104).

AMIDO-NITRO- *v.* NITRO-AMIDO-.

AMIDO - NITRO - BROMO- *v.* BROMO-NITRO-AMIDO-.

AMIDO - NITRO - CHLORO- *v.* CHLORO-NITRO-AMIDO-.

AMIDO-NITRO-IODO- *v.* IODO-NITRO-AMIDO-.

AMIDO-OCTOIC ACID $C_8H_{17}NO_2$ *i.e.* $C_6H_{13}.CH(NH_2).CO_2H$. *Amido - caprilic acid.* From heptoic aldehyde-ammonia (œnanthol-ammonia) and HCN (Erlenmeyer a. Sigel, *A.* 176, 341). Pearly white laminæ, v. sl. sol. alcohol, ether, and cold water. Neutral. Volatilises before fusing. Salts. — $HA'HCl$. — $HA'HNO_3$: slender needles. — $(HA')_2H_2SO_4$. — CuA'_2.

Nitrile $C_6H_{13}.CH(NH_2).CN$. [0°]. From HCN and œnanthol-ammonia (E. a. S.). Oil, miscible with alcohol and ether. Salts.—$C_8H_{16}N_2HCl$: satiny, six-sided plates.—$(C_8H_{16}N_2)_2H_2PtCl_6$.

Amide $C_6H_{13}.CH(NH_2).CONH_2$. From the nitrile and conc. HCl. Salts.—$(C_8H_{18}N_2O)_2H_2PtCl_6$.—$C_8H_{18}N_2OHCl$. Converted by aqueous $NaHCO_3$ into an acid, $C_9H_{18}N_2O_3$ (?).

AMIDO-OCTYL-BENZENE *v.* AMIDO-PHENYL-OCTANE.

AMIDO-OCTYL-TOLUENE *v.* AMIDO-TOLYL-OCTANE.

AMIDO - ŒNANTHYLIC ACID *v.* AMIDO-HEPTOIC ACID.

AMIDO-OPIANIC ACID *v.* OPIANIC ACID.

TRI-AMIDO-ORCIN $C_7H_{11}N_3O_2$ *i.e.* $C_6Me(OH)_2(NH_2)_3$. From tri - nitro - orcin by sodium-amalgam or by Sn and HCl. Its solutions readily oxidise in air, forming amido-di-imido-orcin (*q. v.*) (Stenhouse, *Pr.* 21, 125).

AMIDO-OXALOXYL-ACETIC ACID $CO_2H.CH(NH_2).CO.CO_2H$. *Phenyl hydrazide* $CO_2H.CH(NH_2).C(N_2HPh).CO_2H$. Obtained by reduction of an alkaline solution of the di-phenyl - hydrazide of di - oxy - tartaric acid $C_2(N_2HPh)_2(CO_2H)_2$ with sodium amalgam.

White pp., very oxidisable, its alkaline solution quickly becoming reddish-violet on contact with the air. By warming with H_2SO_4 it is converted into the anhydride $C_{10}H_9N_3O_3$ which is probably oxy-amido-quinizine-carboxylic acid (*q. v.*). By further reduction of the alkaline solution with sodium-amalgam di-amido-succinic acid [125°] is formed (Tafel, *B.* 20, 244).

AMIDO-OXINDOLE *v.* OXINDOLE.

AMIDO-OXY- *v.* OXY-AMIDO-.

AMIDO-PHENANTHRENE *v.* PHENANTHRENE.

AMIDO-DI-PHENIC ACID $C_{14}H_{11}NO_4$ *i.e.* [1:2] $CO_2H.C_6H_4.C_6H_3(NH_2).CO_2H$ [1:5:2]. The hydrochloride, $H_2A''HCl$, obtained from nitro-di-phenic acid, forms silvery laminæ. When distilled with lime it produces *p*-amido-fluorene, $C_{13}H_9NH_2$ [123°] (Stasburger, *B.* 16, 2347).

o-**Di-amido-di-phenic acid** $C_{14}H_{12}N_2O_4$ *i.e.* [3:2:1] $(CO_2H)(NH_2).C_6H_3.C_6H_3(NH_2)(CO_2H)$ [1:2:3]. Formed, by intramolecular change, when *o*-hydrazo-benzoic acid is boiled with HCl (Griess, *B.* 7, 1609).

m-**Di-amido-di-phenic acid** $C_{14}H_{12}N_2O_4 1\frac{1}{2}aq$ *i.e.* [2:4:1] $(CO_2H)(NH_2).C_6H_3.C_6H_3(NH_2)(CO_2H)$ [1:4:2]. *Benzidine di-carboxylic acid.*

Formation.—1. From the corresponding di-nitro-compound (Hummel, *A.* 193, 128; Struve, *B.* 10, 75; Schultz, *B.* 12, 235).—2. From *m*-hydrazo-benzoic acid by boiling with HCl (G.).

Properties.—Short needles (from water); v. sl. sol. water, alcohol, and ether. It gives benzidine and di-amido-fluorene when distilled with lime.

Salts. — $Ag_2A''aq$. — $H_2A''2HCl$. — $H_2A''2HNO_3$.—$H_2A''H_2PtCl_6$ 2aq.

AMIDO-PHENOL.

o-**Amido-phenol** C_6H_7NO *i.e.* $C_6H_4(NH_2)(OH)$ [1:2]. [170°]. S 1·7 at 0° (Körner).

Formation.—1. By reducing *o*-nitro-phenol (Hofmann, *A.* 103, 351; Fritzsche, *A.* 110, 166; Schmitt a. Cook, *K.* 3, 62).

Properties.—Scales; may be sublimed.

Salts.—$B'HCl$; S. ·8 at 0°.—$B'_2H_2SO_4$.

Reactions.—1. *Oxidised* by K_3FeCy_6 forming a dye ($C_{24}H_9N_3O_2$?) which sublimes as pink needles (G. Fischer, *J. pr.* [2] 19, 319).—2. *Nitrous acid* forms *o*-diazo-phenol. — 3. Converted into oxy-quinoline by heating with *glycerin, o-nitro-phenol*, and H_2SO_4 (Skraup, *B.* 15, 893).—4. *Lactic acid, o-nitro-phenol* and H_2SO_4 give oxy-methyl-quinoline (oxy-quinaldine).—5. $CH_2Cl.CO_2H$ gives oxy-phenyl-amido-acetic acid, $CO_2H.CH_2.NH.C_6H_4.OH$ (Vater, *J. pr.* [2] 29, 286). — 6. $Cl.CO_2Et$ gives oxy-phenyl-carbamic ether, $HO.C_6H_4.NH.CO_2Et$, [85°], which is converted by distillation into alcohol and oxy-methenyl-amido-phenol  $C_6H_4<\genfrac{}{}{0pt}{}{N}{O}>C.OH$, [138°] (Grönvick, *Bl.* [2] 25, 178).—7. *Potassic xanthate* converts the hydrochloride of amido-phenol into sulpho-carbanil  $C_6H_4<\genfrac{}{}{0pt}{}{N}{O}>CSH$, called also thio-carbamido-phenol and 'oxy-phenyl-thio-carbimide' (Kalckhoff, *B.* 16, 1825; Zincke a. Hebebrand, *A.* 226, 60).—8. Amido-phenol (30 g.) heated with alcoholic *quinone* (43 g.) forms hydroquinone; and, on cooling, violet needles of a *base* $C_{24}H_{18}N_4O_4$ [250°] separate. This base is soluble in aniline, sparingly soluble in alcohol, benzene, and chloroform. In dilute acids it forms deep red solutions. Boiled with NaOH, ammonia comes off and *o*-amido-phenol and other products are formed. The salts of the base have green metallic lustre and are easily soluble in alcohol but sparingly soluble in water; much water decomposes them into acid and base.—$B''2HCl$.—$B''2HClPtCl_4$.—$B''_2H_2SO_4$. Acetyl derivative $C_{24}H_{16}Ac_2N_4O_4$. [285°]. Oxidised in glacial acetic acid solution by HNO_3, this gives $C_{25}H_{15}N_5O_8$ [27[illegible]°-280°]. Benzoyl derivative $C_{24}H_{16}Bz_2N_4O_4$. [265°]. *Reactions.*—*Nitrous acid* converts the base into $C_{24}H_{10}N_8O_6$, which forms small red needles, [above 290°]. HNO_3 oxidises it in acetic acid solution to a body which crystallises in yellow needles [260°] (Zincke a. Hebebrand, *A.* 226, 60).

Acetyl derivative $C_6H_4(OH)(NHAc)$. [201°]. From its anhydro-derivative by boiling with dilute H_2SO_4 (Ladenburg, *B.* 9, 1525). According to Morse (*B.* 11, 232) it can be formed by reducing *o*-nitro-phenol with Sn and HOAc (*cf.* Zincke a. Hebebrand, *A.* 226, 69). Glittering white plates, v. sol. alcohol and hot water; sol. KOHAq. Not affected by quinone.

Anhydro derivative  $C_6H_4<\genfrac{}{}{0pt}{}{O}{N}>C.CH_3$.

Ethenyl-o-amido-phenol. [201°]. S.G. $\frac{0}{0}$ 1·1365. Formed by heating *o*-amido-phenol with Ac_2O, or its acetyl derivative with P_2O_5 (L.).

Benzoyl derivative $C_6H_4(NHBz)(OH)$. [167°]. From the anhydro-compound by boiling with aqueous acids, or from the di-benzoyl derivative by boiling with water and $BaCO_3$ (Hübner, *A.* 210, 387; Bottcher, *B.* 16, 629). Laminæ, sl. sol. cold water, v. sol. hot water, sol. alcohol, ether, and benzene.

Anhydro derivative  $C_6H_4<\genfrac{}{}{0pt}{}{O}{N}>C.Ph$.

Benzenyl-o-amido-phenol. [103°]. (314°). Formed by heating *o*-amido-phenol with BzCl, HOBz, or phthalic anhydride, and distilling the product (L.); or by reducing *o*-nitro-phenyl benzoate, with Sn and HCl. It is insol. water, v. sol. alcohol. Its salts are unstable, but $B'_2H_2PtCl_6$ may be crystallised from alcohol.

Di-benzoyl derivative $C_6H_4(NHBz)(OBz)$. [176°]. From *o*-amido-phenol hydrochloride and BzCl (Hübner, *A.* 210, 387).

Formyl derivative. Only known in its Anhydro-derivative  $C_6H_4<\genfrac{}{}{0pt}{}{O}{N}>CH$.

Methenyl-amido-phenol. [31°]. (183°). Formed by heating *o*-amido-phenol with formic acid.

Phthalyl derivative $C_6H_4:(C_2O_2):N.C_6H_4.OH$. *Oxy-phenyl-phthalimide.* [220°]. From *o*-amido-phenol and phthalic anhydride at 220°. Yellowish prisms; converted by heat into CO_2 and anhydro-benzoyl-*o*-amido-phenol, and by boiling Na_2CO_3Aq into phthaloxyl-amido-phenol, $CO_2H.C_6H_4.CO.NH.C_6H_4OH$, [223°] (Ladenburg, *B.* 9, 1528).

Methyl derivative $C_6H_4(NH_2).OMe$. *o-Anisidine* (228°). From *o*-nitro-anisol by reduction (Brünck, *Z.* 1867, 205; Mühlhäuser, *B.* 13, 919, *A.* 207, 235; Herold, *B.* 15, 1684). Liquid. It acts upon quinone thus:

$$3C_6H_4O_2 + 2C_6H_4(OMe)NH_2 = 2C_6H_4(OH)_2 + C_6H_2O_2(C_6H_3(OMe)NH_2)_2.$$

The product forms reddish-violet needles (from glacial HOAc and benzene), [230°], and gives a fine blue solution in conc. H_2SO_4 (Zincke, *A.*

226, 68). **Salts.**—B'HCl: needles (from alcohol); may be sublimed.—B'HBr.—$B'H_2SO_4$.—$B'_2H_2PtCl_6$.—Chloroacetate (Vater, *J. pr.* [2] 29, 288). **Acetyl derivative.**—$C_6H_4(NHAc).OMe$. [84°] (204°). Pearly crystals. Sol. hot water. **Benzoyl derivative.** — $C_6H_4(NHBz).OMe$ [59°].

Ethyl derivative $C_6H_4(NH_2).OEt$. *o-Amido-phenetol.* (229°). A liquid prepar[illegible] by reducing *o*-nitro-phenetol (M. Förster, *J. pr.* 129, 344). **Reactions.**—1. *Bromine* forms a di- and a tri-bromo-derivative. — 2. *Cyanogen chloride* passed into an ethereal solution forms ethoxy-phenyl cyanamide, [94°], *o*-amido-phenetol hydrochloride being ppd.:

$$2C_6H_4(NH_2).OEt + CNCl =$$
$$C_6H_4(NH_2)OEtHCl + C_6H_4(NH.CN).OEt$$

(Berlinerblau, *J. pr.* [2] 30, 98). ***Chloroacetate.***—$C_6H_4(NH_2)(OEt)CH_2Cl.CO_2H$ (Vater, *J. pr.* [2] 29, 288).

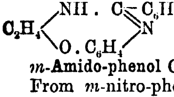
Ethylene derivative $C_2H_4(O.C_6H_4.NH_2)_2$. [128°]. By reducing the ethylene ether of nitro-phenol with Sn and HCl. *Properties.*—Trimetric plates (from alcohol or water). Feels greasy. Insoluble in cold water, soluble in alcohol, ether, chloroform and benzene. Forms a bluish-black solution with H_2SO_4. Fe_2Cl_6 gives a sepia-brown colour. $K_2Cr_2O_7$ and HCl give a brownish-red colour (E. Wagner, *J. pr.* [2] 27, 201). **Salts.** — B''2HCl2aq. Silver-grey glittering flat needles grouped in tufts (from water). The acetate is extremely soluble. The sulphate is the least soluble salt, it crystallises in pearly plates but, like the oxalate, it readily becomes oxidised. **Diacetyl derivative.**—[226°]. Needles.

Oxethyl derivative.— $HO.C_2H_4.O.C_6H_4.NH_2$. [90°]. Got by reducing $BzO.C_2H_4.O.C_6H_4.NO_2$ (*v. o*-NITRO-PHENOL) by Sn and HCl (Weddige, *J. pr.* 132, 252). *Properties.*—Colourless plates, slightly soluble in water, readily soluble in alcohol, ether and boiling benzene. A feeble base. **Benzoyl derivative** $BzO.C_2H_4.O.C_6H_4.NH_2$ [c. 100°]. Got by reducing the benzoyl derivative of the oxethyl ether of *o*-Nitro-phenol (*q. v.*).

Amido-ethyl derivative

$$NH_2.C_2H_4.O.C_6H_4.NH_2$$

Anhydro-benzoyl derivative



[151°] *v. o*-NITRO-PHENOL.

***m*-Amido-phenol** $C_6H_4(NH_2)(OH)$ [1:3].

From *m*-nitro-phenol by reducing with Sn and HCl (Bantlin, *B.* 11, 2106). The free base is extremely unstable. Its hydrochloride, B'HCl, is formed by reducing bromo-*m*-nitro-phenol (Pfaff, *B.* 16, 613).

Methyl derivative $C_6H_4(NH_2)(OMe)$ *m-Anisidine* (251°). **Salt.**—B'HCl (Pfaff).

Ethyl derivative $C_6H_4(NH_2)(OEt)$. (180°–205°) at 100 mm. From the nitro compound by Sn and HCl (P. Wagner, *J. pr.* [2] 32, 71). A yellowish liquid, turning red in air. **Salts.**—$B'_2H_2SnCl_4$: plates.—B'HCl: silky grey needles; insol. ether, sol. water and alcohol. — $B'_2H_2SO_4\,1\frac{1}{2}aq$.—$^{*}B'_2H_2C_2O_4$: brownish plates.—*B'HBr (Staedel, *B.* 16, 29). **Acetyl derivative** $C_6H_4(NHAc)(OEt)$. [97°]. Glittering white plates (from water).

Ethylene derivative $C_2H_4(O.C_6H_4NH_2)_2$. [135°]. Obtained by reducing the corresponding nitro-compound. Short prisms (from alcohol). Sl. sol. hot water, sol. hot alcohol and benzene, sl. sol. ether. Forms crystalline salts.

***p*-Amido-phenol** $C_6H_4(NH_2)(OH)$ [1:4]. [170°] (S. a. C.). [c. 184°] (L.). S. 1·1 at 0°. S. (alcohol) 4·5 at 0°.

Preparation.—1. From *p*-nitro-phenol by reducing with iron and acetic acid (Fritzsche, *A.* 110, 166) or Sn and HCl (Schmitt a. Cook, *Z.* 3, 61).—2. From amido-salicylic acid by distillation (Schmitt, *B.* 1, 67).—3. From nitroso-phenol (Baeyer a. Caro, *B.* 7, 965).

Properties.—Crystalline, but very unstable. May be sublimed (S. a. C.). In capillary tubes it turns brown at 140° and melts at 184° with decomposition (Lossen, *A.* 175, 296).

Salts.—B'HCl. S. 71 at 0°. S. (alcohol) 10. Turns brown in air.—B'HOAc. [183°]. S. 11 at 0°. S. (alcohol) 8·3 at 0°.

Reactions.—1. *Bleaching powder solution* added to a cold solution of *p*-amido-phenol hydrochloride forms quinone chloro-imide, but if added to a hot concentrated solution of the salt it forms a mixture of tri- and tetra-chloroquinones.—2. *Bleaching powder* added to a solution of *p*-amido-phenol in fuming HCl at 0° forms pure tri-chloro-quinone.—3. *Chlorine gas* passed in excess into a solution of *p*-amido-phenol in fuming HCl forms pure tri-chloro-amido-phenol (Schmitt a. Andresen, *J. pr.* 131, 435). The observation that chlorine converts *p*-amido-phenol hydrochloride in aqueous solution into quinone-chloro-imide, while in presence of conc. HCl chlorine converts *p*-amido-phenol into tri-chloro-amido-phenol, is explained by the fact that quinone-chloro-imide is changed by conc. HCl into chloro-*p*-amido-phenols. In this decomposition the first reaction is:

$$C_6H_4{<}\genfrac{}{}{0pt}{}{O}{NCl} + 4HCl = C_6H_4{<}\genfrac{}{}{0pt}{}{OH}{NH_2,HCl} + 2Cl_2.$$

This reaction is similar to that between chloride of nitrogen and HCl:

$$NCl_3 + 4HCl = NH_4Cl + 3Cl_2.$$

Hence both ammonia and amidogen are protected by conc. HCl from the action of chlorine. **4.** Acts on *quinone* as follows:

$$3C_6H_4O_2 + 2NH_2.C_6H_4OH =$$
$$2C_6H_4(OH)_2 + C_6H_2(NH_2.C_6H_3.OH)_2O_2.$$

It is best to use the hydrochloride of *p*-amido-phenol in hot aqueous solution; the product, which separates on cooling, is sparingly soluble in the usual menstrua, and does not melt below 290° (Zincke a. Hebebrand, *A.* 226, 70).—5. HCl, $NaNO_2$, and K_2SO_3 produce *p*-diazo-phenol sulphite, $HO.C_6H_4.N_2.SO_3H$ (Reisenegger, *A.* 221, 316).—6. $Cl.CO_2Et$ forms *p*-oxy-phenyl-carbamic ether, $HO.C_6H_4.NH.CO_2Et$ [120°].—7. A mixture of HCl and *potassium cyanate* produces *p*-oxy-phenyl-urea, $HO.C_6H_4.NH.CO.NH_2$ [168°].—8. HCl and *potassium sulphocyanide* produce, when the solution is evaporated, *p*-oxy-phenyl-thio-urea, $HO.C_6H_4.NH.CS.NH_2$ [214°].—9. CS_2 produces di-oxy-di-phenyl-thio-urea, $CS(NH.C_6H_4.OH)_2$.

Acetyl derivative $C_6H_4(NHAc)(OH)$. [179°]. Large white prisms; obtained by reducing *p*-nitro-phenol with tin and glacial acetic acid (Morse, *B.* 11, 232).

Benzoyl derivative $C_6H_4(NHBz)(OH)$. [227°]. From *p*-amido-phenol and BzCl

(Hübner, *A.* 210, 378). Needles, insol. water, alcohol, and petroleum, sl. sol. hot alcohol.

Amido-phenyl benzoate $C_6H_4(NH_2)(OBz)$. [154°]. Obtained by reducing *p*-nitro-phenyl benzoate. Plates; sol. boiling alcohol, and water, v. e. sol. glacial acetic acid.

Di-acetyl derivative $C_6H_4(NHAc)(OAc)$ [151°]. From *p*-amido-phenol and Ac_2O.

Di-benzoyl derivative $C_6H_4(NHBz)(OBz)$. [231°]. From *p*-amido-phenol and BzCl.

Methyl derivative $C_6H_4(NH_2)(OMe)$. *p-Anisidine*. [56°]. (246°). From *p*-nitro-anisol (Brunk, *Z.* 1867, 205; Salkowski, *B.* 7, 1009). Formed also, together with CO_2, when anisoyl-hydroxylamine is distilled (Lossen, *A.* 175, 296). Tables (from water). B'HCl: long needles. $B'_2H_2PtCl_6$.

Ethyl derivative $C_6H_4(NH_2).OEt$. (253°). Obtained by reducing *p*-nitro-phenetol (Halloch, *B.* 14, 37).

Ethylene derivative $C_2H_4(O.C_6H_4NH_2)_2$ [c. 170°]. By reducing the ethylene ether of *p*-nitro-phenol (*q. v.*). *Properties.*—Needles, which turn brown in the air. Crystallises from alcohol or from water. Very soluble in hot benzene, less soluble in $CHCl_3$ or ether. Forms a deep blue colour with $K_2Cr_2O_7$ and HCl. Fe_2Cl_6 gives a cherry red (E. Wagner, *J. pr.* [2] 27, 206). Salt.—$B''2HCl$: long thin needles grouped concentrically. The acetate is deliquescent. The sulphate is the least soluble salt. The oxalate is but slightly soluble.

(*a*) **Di-amido-phenol** $C_6H_3(OH)(NH_2)_2$ [1:2:4]. From (*a*) di-nitro-phenol (Gauhe, *A.* 147, 66; Stuckenberg, *B.* 10, 385; Post a. Stuckenberg, *A.* 205, 56). The free base is extremely unstable.

Salts.—$B''2HCl$. Precipitated by adding conc. HCl to its aqueous solution. Small prisms insoluble in conc. HCl, and in absolute alcohol. Dilute solutions are turned violet-red by Fe_2Cl_6 or bleaching powder (H. Köhler, *J. pr.* [2] 29, 270).—$B''2HI$.—$B''H_2SO_4 2aq$: tables.

Di-benzoyl derivative $C_6H_3(NHBz)_2OH$ (?). [187°]. From the hydrochloride and BzCl. Pale red leaflets; sol. alcohol, chloroform, and aniline, sl. sol. ether, insol. water. Forms a nitro derivative [c. 169°].

Tri-benzoyl derivative $C_6H_3(NHBz)_2(OBz)$(?). [233°]. Rhombohedra, insol. alcohol, chloroform, and ether; sol. aniline.

(*β*) **Di-amido-phenol** $C_6H_3(NH_2)_2OH$ [2:6:1]. The free base is very unstable; its hydrochloride is got by reducing the corresponding di-nitro-phenol (Post a. Stuckenberg, *A.* 205, 79).

Salts.—$B''2HCl$: thick pointed prisms, v. sol. water, sl. sol. alcohol. $B''H_2SO_4$: yellow needles.

Di-benzoyl derivative $C_6H_3(NHBz)_2OH$. [209°–213°]. Minute crystals, sol. alcohol, sl. sol. benzene.

Tri-benzoyl derivative $C_6H_3(NHBz)(NBz_2)(OH)$. [184°]. Sol. warm Na_2CO_3Aq, insol. chloroform.

Tetra-benzoyl derivative $C_6H_3(NBz_2)(NBz_2)OH$. [182°]. Leaflets; insol. water, sol. warm Na_2CO_3Aq, alcohol, benzene, and ether.

Di-amido-phenol $C_6H_3(OH)(NH_2)_2$. [1:3:4].

Hydrochloride $B''2HCl$.—Formed by heating ethoxy-*p*-amido-phenyl carbamic ether, $C_6H_3(OH)(NH_2)NH.CO_2Et$ with fuming HC (H. Köhler, *J. pr.* [2] 29, 269). Oblong plate Very soluble in conc. HCl and in absolute alcoho Dilute solutions are turned blood-red by Fe_2C or bleaching powder.

Tri-amido-phenol $C_6H_2(NH_2)_3OH$. [2:4:6:1]

Formation.—1. From picric acid by reductio (Heintzel, *Z.* 1867, 338; *B.* 1, 111; Bamberge *B.* 16, 2400).—2. From picramide, Sn and HC (Hepp, *A.* 215, 350). The free base is unstabl The salts give a blue colour with a large quantit of water containing air. In conc. solution Fe_2Cl gives deep blue glittering crystals of amido-di imido-phenol (Heintzel).

Salts.—$B'''3HCl$.—$B'''_2 3H_2SO_4$.—$B'''H_3SnCl$ $1\frac{1}{2}$aq.—$B'''HI\,H_2SO_4 2aq$.—$B'''HIH_3PO_4 2aq$. – $B'''_2H_4FeCy_6$. If the hydrochloride is boil with HCl di-amido-dioxy-benzene is go (Salkowski, *A.* 174, 260).

Tri-acetyl derivative $C_6H_2(NHAc)_3OH$ [263°]. From the hydrochloride of tri-amido phenol by heating with NaOAc and Ac_2O. Whit plates, soluble in acetic acid, hot alcohol, water aqueous acids and alkalis, very sparingly i benzene and acetone; by HNO_3, CrO_3 or Fe_2Cl it is oxidised to the tetra-acetyl derivative o tetra-amido-di-oxy-diphenyl-quinone

$C_6H(NHAc)_2(OH).O$
| | (Bamberger, *B.* 16, 2400).
$C_6H(NHAc)_2(OH).O$

Reaction.—Tri-amido-phenol hydrochlorid is converted by bromine water into 'bromo-dichromazin' $C_{18}H_8N_3Br_{11}O_7$. This bod separates from alcohol in yellow needles wit feeble violet dichroism. Boiling dilute H_2SO converts it into 'bromo-dichroic acid $C_{18}H_7Br_{11}O_{11}$ and ammonia. Bromine convert bromodichromazin into hexa-bromo-aceton (Wedel a. Gruber, *B.* 10, 1137).

Tetra-amido-phenol

Ethyl-ether, hydrochoride $C_6H(NH_2)_4(OEt),2HCl$. By reducing the produc of the action of HCl upon tri-nitro-ethoxy-phenyl urethane.—(1).$C_6H(NO_2)_3(OEt)(NH.CO_2Et) + HC$ $= CO_2 + EtCl + C_6H(NO_2)_3(OEt)NH_2$.

$$(2.)\ C_6H(NO_2)_3(OEt)NH_2 + 9H_2 = C_6H(NH_2)_4OEt + 6H_2O.$$

Properties.—Crystallises from dilute alcohol Insoluble in absolute alcohol, very soluble i water. Does not melt at 360°. Reduces solu-tions of Au and Pt. A feebly acid solution give with Fe_2Cl_6 or bleaching-powder the followin succession of colours: dark-green, violet-red, red dish-brown, yellowish-brown, yellow, colourless.

AMIDO-PHENOL SULPHONIC ACID $C_6H_7NSO_4$ *i.e.* $C_6H_3(NH_2)(OH)HSO_3$. [2:1:4] S. 1 at 14°. Prepared by reduction of *o*-nitro phenol-sulphonic acid or by sulphonation o *o*-amido-phenol. Large colourless crystals lik calc-spar. Does not form salts.

Anilide $C_6H_3(NH_2)(OH)(SO_2.NHPh)$. [205° Colourless needles; soluble in alcohol, acetic acid and benzene insoluble in ether.

Benzoyl derivative $C_6H_3(NHBz)(OH)(SO_3H)$. Salts.—$NaA'4\frac{1}{2}aq$: colourless needles, solubl in water a. alcohol.—BaA'_2; colourless spangles sparingly soluble.—$CaA'_2 4\frac{1}{2}aq$: sparingly solubl colourless scales (Post a. Holst, *B.* 13, 617; *A* 205, 49).

***p*-Amido-phenol sulphonic acid** $C_6H_3(OH)(NH_2)SO_3H$ [1:4:2]. S. ·07 at 14°.

Formation.—1. From *p*-amido-phenol hydrochloride and fuming H_2SO_4 (Post, *B.* 6, 397).—2. From *p*-nitro-phenol sulphonic acid (Post a. Holst, *B.* 13, 617).—3. Together with azoresorufin by heating a mixture of resorcin and nitrobenzene with H_2SO_4 (Brunner a. Krämer, *B.* 17, 1867).—4. From quinone chloro-imide and conc. Na_2SO_3 (Schmitt a. Bennewitz, *J. pr.* [2] 8, 7).

Properties.—White glistening needles; sl. sol. cold water, v. sl. sol. alcohol, insol. ether. Does not combine with acids, but forms metallic salts, *e.g.* $Ba(O.C_6H_3(NH_2)SO_3)$. Reduces cold ammoniacal $AgNO_3$. Turned violet by Fe_2Cl_6. Not ppd. by lead acetate.

Anilide $C_6H_3(OH)(NH_2)SO_2NPhH$. [98°]. Small colourless crystals; v. sol. alcohol, acetic acid, and benzene; insol. ether.

p-**Amido-phenol di-sulphonic acid** $C_6H_2(OH)(NH_2)(SO_3H)_2$ [1:4:2:6] (?). From benzene-azo-phenol tri-sulphonic acid (*q. v.*) by ammonium sulphide (Wilsing, *A.* 215, 236; Limpricht, *B.* 15, 1293). White silky needles. Deliquescent; sl. sol. alcohol, insol. ether. Solution gives with Fe_2Cl_6 a deep violet colour. Its alkaline solutions show blue fluorescence for a short time. Salts.—KHA″aq: slightly sol. cold water.—NH_4HA''aq.—PbA″aq.

o-**AMIDO-DIPHENYL** $C_{12}H_{11}N$ *i.e.* $C_6H_5.C_6H_4.NH_2$ [1:2]. [45°]. From *o*-nitro-diphenyl with tin and glacial acetic acid (Hübner a. Lüddens, *A.* 209, 351).

Salts.—B′HCl: needles.—$B'_2H_2PtCl_6$4aq.: orange leaflets.

p-**Amido-diphenyl** $C_6H_5.C_6H_4.NH_2$ [1:4]. *Xenylamine*; *Martylamine.* [49°]. (320°). Occurs in the high-boiling fractions in the preparation of aniline (Hofmann, *Pr.* 12, 389; G. Schultz, *A.* 174, 212; Osten, *B.* 7, 171). Prepared by reducing *p*-nitro-diphenyl with tin and HCl (Hübner a. Osten, *A.* 209, 339). Colourless leaflets, sol. hot water, alcohol, and chloroform.

Salts.—B′HCl: leaflets.—$B'_2H_2PtCl_6$2aq; yellow leaflets, sl. sol. alcohol.—$B'HNO_3$: pearly leaflets.—$B'_2H_2SO_4$: leaflets, v. sl. sol. water, sl. sol. alcohol.—$B'_2H_2C_2O_4$: long needles, sol. water and alcohol.

Acetyl derivative $C_6H_5.C_6H_4.NAcH$. [167°]. Long needles; v. sl. sol. water.

Benzoyl derivative $C_6H_5.C_6H_4.NBzH$. [230°]. Leaflets; insol. water, v. sl. sol. alcohol.

Formyl derivative $C_6H_5.C_6H_4.NH.CHO$. [172°]. Prepared by heating *p*-amido-diphenyl with ethyl formate at 100°. Minute needles; sol. ether, sl. sol. alcohol, v. sl. sol. water (Zimmermann, *B.* 13, 1967).

p-**Amido-diphenyl sulphonic acid** $C_{12}H_8(NH_2)SO_3H$. [above 300°]. Formed by sulphonation of *p*-amido-diphenyl (Carnelley a. Schlevelman, *C. J.* 49, 380). Insol. water.

Salts.—NaA′2aq: colourless needles, m. sol. water.—$BaA'_2$4aq; v. sl. sol. water.

o-p-**Di-amido-diphenyl** $C_{12}H_{12}N_2$ *i.e.* [1:2] $NH_2.C_6H_4.C_6H_4.NH_2$ [1:4]. *Iso-benzidine.* (β)- or (δ)-*Di-amido-di-phenyl.* *Diphenyline.* [45°]. (363°) (Schultz, *A.* 207, 348).

Formation.—1. From *o*-nitro-*p*-amido-diphenyl (Schultz, *B.* 9, 548; 14, 612).—2. From di-amido-diphenyl carboxylic acid (Strasser a. Schultz, *A.* 210, 193).

Preparation.—An alcoholic solution of azobenzene (100 g.) is heated with a solution of $SnCl_2$ in conc. HCl; the liquid is evaporated to dryness, the residue dissolved in water and benzidine is ppd. as sulphate (100 g.) while *o-p*-di-amido-diphenyl sulphate (30 g.) remains in solution (Schmidt a. Schultz, *B.* 12, 482).

Properties.—Long needles, v. sl. sol. water.

Salts.—B″HCl: laminæ.—B″2HCl: needles.—$B''H_2SO_4$: prisms.—$B''_2H_2SO_4$.

Di-acetyl derivative $C_{12}H_{10}Ac_2N_2$. [202°].

m-m-**Di-amido-diphenyl** [1:3] $NH_2.C_6H_4.C_6H_4.NH_2$ [1:3]. From the nitro compound (Brunner a. Witt, *B.* 20, 1028). Crystals, sl. sol. water.—$B''H_2SO_4$.—$B''H_2PtCl_6$.

Di-acetyl derivative. [258°]. Long needles.

p-p-**di-Amido-diphenyl.** *Benzidine.* [1:4] $NH_2.C_6H_4.C_6H_4.NH_2$ [1:4]. *Xenylene-diamine.* [122°]. (above 360°).

Formation.—1. By the reduction of azobenzene or of azoxybenzene in alcoholic solution by SO_2 (Zinin, *A.* 85, 328).—2. From azobenzene by $SnCl_2$ and HCl (*v. sup.*).—3. By heating azobenzene with fuming HCl (Zinin, *A.* 137, 376), HBr (Werigo, *A.* 165, 202), or HI (Senziuk, *Z.* 1870, 267) in sealed tubes.—4. By reducing nitro-benzene with sodium-amalgam in presence of acetic acid, the product being treated with H_2SO_4 (Werigo, *A.* 135, 176).—5. From nitro-benzene, alcoholic NaOH, and zinc dust and subsequent treatment with acid (Alexejeff, *Z.* 1867, 497).—6. From di-amido-diphenic acid by distilling with BaO (Schultz, *A.* 196, 29).—7. From *p*-amido-*p*-nitro-diphenyl by Sn and HCl (Fittig, *A.* 124, 276).—8. From *p-p*-di-nitro-phenyl by tin and HCl (Schultz, *A.* 174, 227).—9. From hydrazo-benzene by treatment with mineral acids:

$$C_6H_5.NH.NH.C_6H_5 = NH_2.C_6H_4.C_6H_4.NH_2.$$

Preparation.—*V. o-p-di*-AMIDO-DIPHENYL.

Properties.—Silvery scales; may be sublimed. Sol. hot water, v. sl. sol. cold water, v. e. sol. alcohol and ether.

Salts.—$B''H_2SO_4$: small scales, v. sl. sol. water and alcohol.—B″2HCl: laminæ, v. sol. water and alcohol.—B″HCl: long needles, sl. sol. water; ppd. when a large excess of water is added to the preceding salt.—$B''2HNO_3$: four-sided laminæ, sol. hot water.—$B''_2H_2C_2O_4$: groups of silky needles, m. sol. water and alcohol.—$B''C_4H_6O_6$: laminæ; sol. water.

Reactions.—1. Even very dilute solutions give with *potassic bichromate* a deep blue pp. (Julius, *M.* 4, 193).—2. K_3FeCy_6 gives a blue pp.—3. *Chlorine-water* gives a blue colour soon becoming red.—4. Exhaustive *chlorination* with $SbCl_5$ gives per-chloro-diphenyl and per-chlorobenzene (Merz a. Weith, *B.* 16, 2874).—5. If very dilute *bromine-water* be poured up[illegible] a solution of benzidine in CS_2 the upper layer becomes blue, excess of bromine destroys this colour, the lower layer then turning red (Claus a. Risler, *B.* 14, 83).

Acetyl derivative $NH_2.C_6H_4.C_6H_4.NAcH$. [199°]. Needles, sl. sol. water.

Diacetyl derivative $NHAc.C_6H_4.C_6H_4.NAcH$. [317°]. Nearly insoluble in all solvents.

Di-formyl derivative $C_{12}H_8(NH.COH)_2$: crystalline powder, sublimable, insoluble in all ordinary solvents except nitrobenzene. Formed

by heating hydrazobenzene or benzidine with formic acid.

Di-benzoyl derivative $C_{12}H_8(NHBz)_2$: colourless needles or pearly plates; insol. alcohol, ether, and aniline; sol. nitrobenzene. Formed by heating hydrazobenzene or benzidine with BzCl (Stern, *B.* 17, 379).

Di-phthalyl derivative $C_{28}H_{16}N_2O_4$ [above 360°]: silky yellow needles, sol. hot nitro-benzene; insol. most other solvents. Formed by heating benzidine & hydrazobenzene with phthalic anhydride (Bandrowski, *B.* 17, 1181).

Oxalyl derivative $(C_6H_4.NH)_2C_2O_2$. An insoluble powder, obtained by heating benzidine oxalate at 200°.

Benzidine-v-sulphonic acid $H_2N.C_6H_4.C_6H_4.NH.SO_3H$. Formed by heating an alcoholic solution of azobenzene with hydric ammonium sulphite (Spiegel, *B.* 18, 1481).

Gelatinous pp. It gives colourless crystalline salts.

The HSO_3 is readily split off with production of benzidine by dissolving the acid in strong H_2SO_4.

Benzidine sulphonic acid (?) $C_6H_4(NH_2).C_6H_3(NH_2)(SO_3H)$ (?). *Hydrazo-benzene sulphonic acid* $C_6H_5.NH.NH.C_6H_4.SO_3H$ (?). Ppd. by adding HCl to the product of the action of H_2S on an ammoniacal solution of azo-benzene sulphonic acid (Griess, *A.* 154, 213).—Yellow needles or plates (from water).—BaA'_2: plates. The free acid is decomposed by solution in aqueous NH_3 into benzidine and H_2SO_4. The above azobenzene sulphonic acid is converted by potash-fusion into *p*-oxy-azobenzene, and would therefore appear to be a *p*-sulphonic acid; in which case it is not clear how the conversion into a benzidine derivative could be effected. If, however, the acid is hydrazo-benzene sulphonic acid, we must assume that the benzidine transformation here takes place in alkaline solution, by displacement of SO_3H. In any case the removal of SO_3H by ammonia is peculiar.

Benzidine sulphonic acid $C_{12}H_{11}N_2(SO_3H)\,2\tfrac{1}{2}aq$. Obtained by heating (*a*)-benzidine disulphonic acid with water at 210° (Limpricht, *B.* 11, 1048). Yellow needles (from alcohol); v. sol. water.—$KA'4aq$.—$BaA'_2 4aq$.—$PbA'_2 3aq$.

Chloride $C_{12}H_{11}N_2(SO_2Cl)$ [above 210°].

Benzidine disulphonic acid $[4:3:1]C_6H_3(NH_2)(SO_3H).C_6H_3(SO_3H)(NH_2)[1:3:4]$ S. ·08 at 22°. From azo-, or azoxy-, benzene disulphonic acid by reduction with $SnCl_2$, sodium-amalgam, or NaOH and zinc dust, followed by treatment with a mineral acid (Mährenholtz a. Gilbert, *A.* [illegible], 337; Brunnemann, *A.* 202, 344; Limpricht, *B.* 14, 1359). Monoclinic prisms (with 3aq). Dilute HCl at 230° gives benzidine and H_2SO_4. Nitrous acid diazotises this acid.—$Na_2A''3\tfrac{1}{2}aq$.—$K_2A''1\tfrac{1}{2}aq$.—$CaA''4aq$.—$BaA''4aq$.—$PbA''4aq$.

Benzidine di-sulphonic acid $C_{12}H_6(NH_2)_2(SO_3H)_2$. From benzidine and fuming H_2SO_4 at 170°. Small white plates; v. sl. sol. water, insol. alcohol and ether (Griess, *B.* 14, 300). Salts.—$BaA''5aq$: white plates.—$BaA''2aq$: needles.—$^{\times}Ag_2A''$: white crystalline pp.

Benzidine (*a*)-di-sulphonic acid $C_{12}H_{10}N_2(SO_3H)_2$. *Hydrazo-benzene di-sulphonic acid* (?). Prepared by reducing potassium azobenzene (*a*)-di-sulphonate with $SnCl_2$ (Limpricht *B.* 14, 1357). Tables (containing 2aq); sl. sol cold water, v. sl. sol. alcohol.—$K_2A''3aq$.—$BaA''aq$.—$^{\times}Ag_2A''$: white pp.—PbA'': needles sl. sol. cold, v. sol. hot, water.

Benzidine tetrasulphonic acid $C_{12}H_8N_2(SO_3H)_4$. Prepared by sulphonation of the preceding with fuming H_2SO_4.—$Ba_2A''''14aq$: large prisms, v. sol. hot water, sl. sol. alcohol.—$^{\times}K_4A''''$ (Limpricht, *B.* 14, 1513).

Other sulphonic acids of benzidine Benzidine heated with a large excess of fuming H_2SO_4 above 170° forms a mixture of di-, tri-, and tetra-, sulphonic acids, and di-amido-diphenylene sulphone sulphonic acids (Griess, *B.* 18, Ref. 88).

Benzidine di-carboxylic acid *v. di*-AMIDO-DIPHENIC ACID.

Benzidine tetra-carboxylic anhydride

$$O\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle C_6H_2(NH_2).C_6H_2(NH_2)\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle O.$$

[above 360°]. Formed by the action of an HCl solution of $SnCl_2$ on azo-benzene tetra-carboxylic acid (azo-phthalic acid). Light-yellow tasteless powder. Insol. water, alcohol, ether, or dilute acids.

With alkalis it gives anhydride salts:—

$C_{12}H_8N_2(C_2O_3)(CO_2K)_2 5aq$: large prisms.

$C_{12}H_8N_2(C_2O_3)(CO_2Na)_2 aq$: small needles.

$C_{12}H_8N_2(C_2O_3)(CO_2Ag)_2$: fine powder.

$C_{12}H_8N_2(C_2O_3)(CO_2)_2Pb$: amorphous powder.

$C_{12}H_8N_2(C_2O_3)(CO_2NH_4)(CO_2H)$: transparent prisms (Claus a. Hemmann, *B.* 16, 1759).

Di-amido-diphenyl $C_{12}H_{12}N_2$. *Iso-benzidine.* [125°]. Occurs among the products obtained by passing aniline through a red-hot tube (Bernthsen, *B.* 19, 420). White iridescent plates, sl. sol. water. Its aqueous solution gives no colouration with *potassic ferricyanide*, and a greyish-brown pp. with *chlorine water.* The solid base is turned greenish-black by strong HNO_3. The *sulphate* is sparingly soluble.

Tetra-amido-diphenyl $[3:4:1]\ (NH_2)_2C_6H_3.C_6H_3(NH_2)_2\ [1:3:4]$. Obtained by reducing di-nitro-*p*-*p*-di-amido-diphenyl (Brunner a. Witt, *B.* 20, 1025). Silvery plates.

***a*-AMIDO-PHENYL-ACETIC ACID** $C_8H_9NO_2$ *i.e.* $C_6H_5.CH(NH_2).CO_2H$. Phenyl-amido-acetic acid. [256°]. Formed by heating *a*-bromo-phenyl-acetic acid with NH_3Aq (S.G. ·9) at 100° (Stöckenius, *B.* 11, 2002); or by saponifying its nitrile, obtained by the action of alcoholic NH_3 on the cyanhydrin of benzoic aldehyde (Tiemann a. Friedländer, *B.* 14, 1967). White leaflets or prisms; may be sublimed. Sl. sol. cold water, m. sol. hot water. It forms unstable salts with bases, but more stable salts with acids, though these are decomposed by water. Distilled with lime, it gives benzylamine (Tiemann, *B.* 13, 383).

Salts.—$B'HCl$: trimetric prisms.—$B'HNO_3$.—$B'H_2SO_4$.—$B'H_2C_2O_4$.—AgA': prisms, v. sl. sol. water.—BaA'_2: small white plates; v. sol. hot water.—$MgA'_2\tfrac{1}{2}aq$: plates, sl. sol. water.

Amide. The hydrochloride forms thick prisms, sl. sol. alcohol.

Nitrile $C_6H_5.CH(NH_2).CN$. Yellow oil (*v. sup.*).

m-Sulphonic acid $C_6H_4(SO_3H).CH(NH_2).CO_2H$. Minute needles; sl.

sol. cold water, insol. ether (Plöchl a. Loë, *B.* 18, 1182).

o- **Amido-phenyl-acetic acid.** When *o*-nitro-phenyl-acetic acid is reduced the product is not *o*-amido-phenyl-acetic acid but its anhydride, oxindol (*q. v.*) (Baeyer, *B.* 11, 583).

m-**Amido-phenyl-acetic acid** $C_6H_4(NH_2).CH_2.CO_2H$ [1:3]. [148°]. Formed by reducing *m*-nitro-phenyl-acetic acid (Gabriel a. Bergmann, *B.* 16, 2065).

Nitrile $C_6H_4(NH_2).CH_2.CN$. *m- Amido-benzyl cyanide.* A liquid obtained by reducing *m*-nitro-phenyl-acetonitrile (Salkowski, *B.* 17, 506).

p-**Amido-phenyl-acetic acid** $C_6H_4(NH_2).CH_2.CO_2H$ [1:4]. [200°]. From *p*-nitro-phenyl-acetic acid (Radziszewski, *B.* 2, 209; Bedson, *C. J.* 37, 92). White needles (from water); v. sl. sol. cold water.

Nitrile $C_6H_4(NH_2).CH_2.CN$. *p-Amido-benzyl cyanide.* [46°]. (312°). V.D. 4·78 (for 4·56). *Formation.*—1. From *p*-nitro-benzyl cyanide (Szumpelik, *B.* 3, 474; Gabriel, *B.* 15, 834).—2. As one of the products of the reduction of *α*-*p*-di-nitro-cinnamic ether (*q. v.*) by tin and HCl (Friedländer a. Mähly, *A.* 229, 229). The yield is 15 p.c. of the substance used. *Properties.*—Satiny plates (from water). Sol. acids. Gives a di-bromo-derivative. HCl at 130° converts it into amido-phenyl-acetic acid. Salts.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$. Acetyl derivative $NHAc.C_6H_4.CH_2.CN$. [97°]. Slender needles; v. sol. alcohol and ether. Di-acetyl derivative $NAc_2.C_6H_4.CH_2CN$. [153°]. Glistening needles. Sol. boiling water, benzene, and CS_2; sl. sol. alcohol.

Di-amido-phenyl-acetic acid $C_6H_3(NH_2)_2.CH_2CO_2H$ [4:3:1]. Formed by reducing (3, 4, 1)-nitro-amido-phenyl-acetic acid (Gabriel, *B.* 15, 1996). Short flat crystals (with aq). Sl. sol. hot alcohol, insol. ether, CS_2, chloroform, and benzene. Sol. acids and alkalis.

α-m-**Di-amido-phenyl-acetic acid** [1:3] $C_6H_4(NH_2).CH(NH_2).CO_2H$. [214°]. Formed by reducing *m*-nitro-phenyl-*α*-amido-acetic acid with tin and HCl (Plöchl a. Loë, *B.* 18, 1181). Flat silvery needles.

Salt.—CuA'_2: bluish-green crystalline pp.

o-**AMIDO-PHENYL-ACETYLENE** C_8H_7N *i.e.* $C_6H_4(NH_2).C{:}CH$. Yellowish oil. Prepared by reduction of *o*-nitro-phenyl-acetylene with zinc-dust and NH_3. It forms yellow pps. with ammoniacal $AgNO_3$ and Cu_2Cl_2.

$B'HCl$: soluble yellow crystals.

Reaction.—Converted by H_2SO_4 (12 pts.) and H_2O (4 pts.) into *o*-amido-acetophenone (Baeyer a. Bloem, *B.* 17, 964).

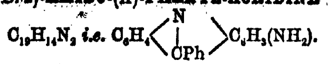
Acetyl derivative. [75°]. Colourless needles (Baeyer a. Landsberg, *B.* 15, 60).

Di-*o*-amido-di-phenyl-diacetylene $C_6H_4(NH_2).C{:}C.C{:}C.C_6H_4(NH_2)$. [128°]. Prepared by the action of a solution of potassium ferricyanide on the cuprous compound of *o*-amido-phenyl-acetylene. Long yellowish needles. Sol. alcohol, ether and acids, insol. water.

$B''H_2Cl_2$: colourless soluble crystals.

Di-acetyl derivative. [231°]. Long needles (Baeyer a. Landsberg, *B.* 15, 60).

(*B.* 2)-**AMIDO-(*A*)-PHENYL-ACRIDINE**



$C_{19}H_{14}N_2$ *i.e.* $C_6H_4{<}\begin{matrix}N\\|\\CPh\end{matrix}{>}C_6H_3(NH_2)$.

Formed by heating phenyl-*p*-phenylene-diamine $C_6H_4(NH_2).NHC_6H_5$ with benzoic acid and $ZnCl_2$ (Hess a. Bernthsen, *B.* 18, 692). Amorphous solid. Easily soluble in ordinary solvents. The solutions of the base are yellow, the benzene and ethereal solution having a splendid green fluorescence. It dyes silk a brownish yellow. The solutions of its salts are red.

Di-amido-phenyl-acridine *v.* CHRYSANILINE.

AMIDO-PHENYL-ALANINE *v.* DI-AMIDO-PHENYL-PROPIONIC ACID.

AMIDO-PHENYL-AMIDO- *v.* DI-AMIDO-PHENYL- or PHENYL-DI-AMIDO-.

AMIDO-DI-PHENYL-AMINE $C_{12}H_{12}N_2$ *i.e.* $NH_2.C_6H_4.NH.C_6H_5$. [61°]. Prepared by the reduction of nitro-di-phenyl-amine or of phenyl-amido-benzene-azo-benzene, or its sulphonic acid (*Tropæolin* O O.) (Nietzki a. Witt, *B.* 12, 1399).

Thin laminæ. Gives quinone on oxidation.

Salt. $B'_2H_2SO_4$: silvery laminæ, sl. sol. water.

Acetyl derivative $C_{12}H_{11}AcN_2$. [158°].

p-p-**Di-amido-di-phenyl-amine** $NH_2.C_6H_4.NH.C_6H_4.NH_2$. [158°]. Formed by reduction of aniline black. Prepared by reducing (*α*)-di-nitro-di-phenyl-amine (N. a. W.).

Acetyl derivative. [239°].

Di-amido-di-phenyl-amine. Prepared by reducing (*β*)-di-nitro-di-phenyl-amine. Liquid.

Salts.—$B''H_2Cl_2$; sl. sol. water.—$B''H_2PtCl_6$.

Acetyl derivative. [203°].

Tri-amido-tri-phenyl-amine $(C_6H_4.NH_2)_3N$. [230°]. Formed by the reduction of tri-nitro-tri-phenyl-amine by $SnCl_2$ (Heydrick, *B.* 18, 2157; 19, 759.)

Salts.—$B'''3HCl$: needles. Its solution exhibits the following colour reactions: blue, turning violet with Fe_2Cl_6; bluish-green with ppd. MnO_2; blue with $K_2Cr_2O_7$; red with chloranil in acetic acid (but if in this case the free base is used the colour is bluish-green).—$B'''_23H_2PtCl_6$.—$B'''(C_6H_2(NO_2)_3OH)_3$.

Tri-acetyl derivative $N(C_6H_4.NHAc)_3$: needles which do not melt below 240°.

AMIDO-PHENYL-BENZGLYCOCYAMINE *v.* AMIDO-DI-PHENYL GUANIDINE CARBOXYLIC ACID.

p-**AMIDO-PHENYL-*iso*-BUTANE** $C_{10}H_{15}N$ *i.e.* $C_4H_9.C_6H_4NH_2$. *Butyl-phenylamine. Amido-butyl-benzene.* (230°). S.G. $\frac{25}{25}$ ·937. From aniline hydrochloride (10 g.) and iso-butyl alcohol (8 g.) by heating for 6 hours at 230° (A. Studer, *A.* 211, 237; *B.* 14, 1472, 2186; Pahl, *B.* 17, 1232). Colourless oil; v. sl. sol. water, volatile with steam. Miscible with alcohol or ether. Nitrous acid converts it into butyl-phenol.

Salts.—$B'HCl$.—$B'HBr$.—$B'HI$.

Acetyl derivative [170°]: laminæ.

Formyl derivative $C_{10}H_{13}.NH.CHO$ [59°]: laminæ (Gasiorowski a. Merz, *B.* 18, 1009).

AMIDO-PHENYL-BUTINENE $C_{10}H_{11}N$ probably

$C_6H_4(\overset{(3)}{NH_2}).\overset{(1)}{CH_2}.CH{<}\begin{matrix}CH\\\|\\CH\end{matrix}$. [98°].

(272° at 718 mm.). V.D. = 4·95 (for 5·02). Formed by reduction of *m*-nitro-*α*-methyl-cinnamic aldehyde in alcoholic solution with tin and HCl. Colourless glistening plates. Sublimes at 100°. Reduces ammoniacal $AgNO_3$. The

hydrochloride, sulphate and nitrate are easily soluble in water. The hydrochloride forms colourless glistening plates. $B'_2H_2Cl_2PtCl_4 2aq$: slender needles.

Acetyl derivative $C_{10}H_{10}NAc$ [140°]: colourless concentric prisms.

Benzylidene derivative $C_{10}H_9N{:}CHPh$ [73°]: concentric light-yellow needles. Formed by heating the base with benzaldehyde (Miller a. Kinkelin, *B.* 19, 1249).

***o*-AMIDO-PHENYL-CARBAMIC ETHER** $C_9H_{12}N_2O_2$ *i.e.* $H_2N.C_6H_4.NH.CO_2Et$. *o-Amido-phenyl-urethane.* [86°]. Formed by reducing *o*-nitro-phenyl-carbamic ether (Rudolph, *B.* 12, 1295). Long colourless needles; sol. water.

Salt.—B'HCl: large tables.

***p*-Amido-phenyl-carbamic ether.** *Amido-carbanilic acid.* [74°]. Formed by reducing *p*-nitro-phenyl-carbamic ether (Hager, *B.* 17, 2626; Behrend, *A.* 233, 10). Needles (from dilute alcohol); insol. water.

Salts.—B'HCl: long needles.—$B'H_2SO_4$.—$B'H_2C_2O_4$: needles, sol. hot water, sl. sol. cold water.—$B'_2H_2PtCl_6$: brown pp.—$(B'HCl)_3SnCl_4$. $B'_2SnCl_2 aq$.—$(B'HCl)_4HgCl_2$.

Benzoyl derivative $C_6H_4(NHBz).NH.CO_2Et$, [230°]: needles; sl. sol. alcohol, insol. water.

Di-*p*-amido-di-phenyl-carbamic ether $(C_6H_4.NH_2)_2N.CO_2Et$. *Di-p-amido-di-phenyl-amine urethane.* [101°]. Formed by reduction of di-*p*-nitro-di-phenyl-carbamic-ether. Violet needles (+aq). Soluble in water.

Di-benzoyl derivative $(C_6H_4.NHBz)_2N.CO_2Et$ [235°]: nearly colourless amorphous solid (Hager, *B.* 18, 2576).

DI-AMIDO-DI-PHENYL-CARBINOL $C_{13}H_{14}N_2O$ *i.e.* $C_6H_4(NH_2).CH(OH).C_6H_4NH_2$. (β)-*Di-amido-benzhydrol.* [128°–129°]. From (β)-di-amido-benzophenone [149°] and sodium amalgam (W. Staedel, *A.* 218, 350). Glittering plates. Salts.—$B''2HCl 2aq$.—$B''H_2SO_4 2aq$.

Acetyl-derivative. [220°].

Di-amido-tri-phenyl-carbinol $C_{19}H_{18}N_2O$ *i.e.* $C_6H_5C(OH)(C_6H_4NH_2)_2$ [below 100°].

Formation. — By the action of aniline in presence of H_2SO_4 upon the chloride $\underbrace{C_6H_5.CCl.C_6H_4.NH}$.

Preparation.—From aniline hydrochloride (40 pts.), nitrobenzene (45 pts.), benzo-trichloride (40 pts.), and Fe at 180°. $C_6H_5CCl_3 + 2C_6H_5NH_2 = C_6H_5CCl(C_6H_4NH_2)_2 + 2HCl$. The mass is extracted with dilute HCl (which leaves some blue colouring matters undissolved) and the nitro-benzene is distilled off by steam (Doebner, *B.* 15, 234; *A.* 217, 242).

Properties. — Small crystals (from dilute alcohol). Insol. in cold water; v. sol. alcohol or benzene. On heating with MeI it gives malachite green.

Salts.—Dilute acids dissolve it in the cold, forming nearly colourless solutions which on boiling (split off water and) change to deep reddish-violet. The salts dye violet, but the shades are not fast. The coloured salts are probably of the form $C_6H_5C{<}^{C_6H_4NH_2}_{C_6H_4NH_2 \cdot Cl}$. This salt forms dark blue needles with coppery lustre.

Reaction.—Zinc dust and HCl reduce it to di-amido-tri-phenyl-methane (*q. v.*).

Tri-amido-tri-phenyl-carbinols *v.* ROSANILINE.

DI-AMIDO-TRI-PHENYL-CARBINOL CARBOXYLIC ANHYDRIDE $C_{20}H_{16}N_2O_2$ *i.e.* $(C_6H_4NH_2)_2\underbrace{C.C_6H_4.CO.O}$. [265°–266°]. Small colourless needles. Is prepared by heating phenolphthaleïn with aqueous NH_3. Gives a *tetra-bromo-derivative* [280°], and a *tetra-acetyl-tetra-bromo-derivative* [241°] (Baeyer a. Burkhardt, *B.* 11, 1297).

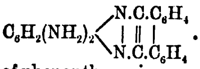
AMIDO-DIPHENYL CARBOXYLIC ACID *v.* AMIDO-DIPHENIC ACID.

DI-AMIDO-DI-PHENYLENE KETONE OXIDE (so called) $C_{13}H_{10}N_2O_2$ *i.e.* $C_{13}H_6(NH_2)_2O_2$. *Lactone of oxy-di-amido-diphenyl carboxylic acid.* From the nitro compound by Sn and HCl (A. G. Perkin, *C. J.* 43, 190). Orange needles (from xylene). Very slightly soluble in boiling water. Ruby prisms (from dilute alcohol).

Salts. — Forms two hydrochlorides. — $(B''HCl)_2PtCl_4$.—$B''(2HCl)PtCl_4$.

AMIDO-PHENYLENE OXIDE C_6H_5NO *i.e.* $C_6H_3(NH_2)O$ (?). *Di-amido-di-phenylene di-oxide.* From nitro-phenylene oxide by alcoholic ammonium sulphide (Märker, *A.* 124, 251). Yellow needles, sl. sol. water, v. sol. hot alcohol.—$B'_2H_2PtCl_6$.

DI-AMIDO-DIPHENYLENE-QUINOXALINE



$C_6H_2(NH_2)_2{<}^{N.C.C_6H_4}_{N.C.C_6H_4}$. Formed by the action of phenanthraquinone upon tetra-amido-benzene [1:2:4:5]. Orange-yellow needles. Nearly insol. acetic acid. Weak base. Dissolves in conc. H_2SO_4 with a greenish-blue colour, passing through violet into red on dilution (Nietzki a. Hagenbach, *B.* 20, 338).

AMIDO-PHENYLENE-UREA $C_7H_7N_3O$ *i.e.*

$OC{<}^{NH}_{NH}{>}C_6H_3(NH_2)$ [1:2:4]. Formed by reducing di-nitro-phenyl-urethane with tin and HCl (Hager, *B.* 17, 2631).

Salts. — $B''H_2SnCl_4$: long needles. — $B''C_6H_2(NO_2)_3OH$: greenish-yellow needles.

***o*-AMIDO-PHENYL-ETHANE** $C_8H_{11}N$ *i.e.* $C_6H_4(NH_2).CH_2.CH_3$ [1:2]. *o-Ethyl-phenyl-amine. o-Amido-ethyl-benzene.* (211°). S.G. $\frac{22}{}$ ·983. From *o*-nitro-phenyl-ethane, tin, and HCl (Beilstein a. Kuhlberg, *A.* 156, 206). Liquid at –10°. Salt.—$B'HNO_3$.

Acetyl derivative $C_8H_{10}AcN$. [112°]. (305°).

Benzoyl derivative $C_8H_{10}BzN$. [147°]: small glittering plates (Paucksch, *B.* 17, 2800).

***o*-Amido-phenyl-ethane sulphonic acid** $C_6H_3Et(NH_2).SO_3H$. Formed by sulphonation of the acetyl derivative. White needles (P.).

***p*-Amido-phenyl-ethane** $C_6H_4(NH_2).CH_2.CH_3$ [1:4]. *p-Ethyl-phenyl-amine.* '*Phenethylamine.*' [–5°]. (214°). S.G. $\frac{22}{}$ ·975. From *p*-nitro-phenyl-ethane by reduction (B. a. K.) or from aniline by heating with ethyl alcohol and $ZnCl_2$ (Benz, *B.* 15, 1647). Formed also when ethyl-aniline hydrochloride is heated at 300° (Hofmann, *B.* 7, 526). Colourless oil; volatile with steam. Salts.—×$B'HNO_3$: small needles or prisms, sl. sol. cold, v. sol. hot, water.—$B'_2H_2SO_4$: large white plates, sl. sol. cold water, m. sol. dilute H_2SO_4.—B'HCl.—$B'_2H_2PtCl_6$.

Acetyl derivative $C_6H_4(NHAc).C_2H_5$ [95°]. (316°).

Benzoyl derivative $C_6H_4(NHBz)C_2H_5$. [151°]: long needles (P.).

ω-Amido-phenyl-ethane $C_6H_5.CH_2.CH_2.NH_2$. [198°]. *Phenylethyl-amine.*

Formation.—1. By dry distillation of α-amido-phenyl-propionic acid (*q. v.*) (Schulze a. Barbieri, *J. pr.* [2] 27, 346; Erlenmeyer a. Lipp, *A.* 219, 202).—2. By action of zinc and HCl upon the cyanhydrin of benzoic aldehyde, or upon amygdalin (Fileti, *B.* 12, 297, 1700).—3. By action of bromine on an alkaline solution of phenyl-propionamide (Hofmann, *B.* 18 2740).

Preparation. — By reducing an alcoholic solution of benzyl cyanide with zinc and HCl (Bernthsen, *A.* 184, 290), di-phenylethyl-amine $(C_6H_5.CH_2.CH_2)_2NH$, and tri-phenylethyl-amine $(C_6H_5CH_2CH_2)_3N$, being also formed (Spica, *G.* 1875, 124; 1879, 566).

Properties.—Liquid; sl. sol. water. Absorbs CO_2 from the air, being converted into a solid carbonate [105°], out of which, on heating, another carbonate, [88°], sublimes. Oxidised to benzoic acid by chromic mixture.

Salts.—B'HCl, [217°]: trimetric tablets (from cold alcohol) or satiny plates (from alcohol-ether): v. sol. alcohol or water, insol. ether.—$B'_2H_2PtCl_6$; more soluble in hot water than in hot alcohol.

Di-amido-di-phenyl-ethane *v.* DI-AMIDO-DI-BENZYL.

ω-AMIDO-TRI-PHENYL-ETHANE $C_{20}H_{19}N$ *i.e.* $CPh_3.CH_2.NH_2$. [116°]. From tri-phenyl-aceto-nitrile by reduction with zinc and HCl. Crystals; v. sol. ether, sl. sol. cold alcohol. The hydrochloride forms needles, [247°], v. sl. sol. water, v. sol. alcohol (Elbs, *B.* 17, 700).

AMIDO-PHENYL-ETHYLENE *v.* AMIDO-STYRENE.

Di-p-amido-di-phenyl-ethylene $C_{14}H_{14}N_2$ *i.e.* $C_2H_2(C_6H_4.NH_2)_2$. *Di-amido-stilbene.* [227°].

Formation.—1. By reduction of di-*p*-nitro-di-phenyl-ethylene with tin and HCl.—2. By reduction with $SnCl_2$ of the brownish-red product of condensation (azoxy-di-phenyl-ethylene?) obtained by the action of sodium methylate or alcoholic NaOH upon *p*-nitro-toluene.

Reactions.—By *nitrous acid* it is converted into a tetrazo-compound which by combination with the sulphonic acids of amines and phenols yields a series of colouring-matters which dye cotton from a soap bath. Thus (α)-naphthol-sulphonic acid gives a bluish-violet, (β)-naphthol-(R)-di-sulphonic acid a blue, (α)-naphthylamine-sulphonic acid a red, and salicylic acid a yellow, colouring-matter.

Di-acetyl derivative $C_2H_2(C_6H_4.NHAc)_2$: [312°] (Bender a. Schultz, *B.* 19, 3234).

Di-p-amido-di-phenyl-ethylene-di-carboxylic anhydride $\begin{matrix}C_6H_4(NH_2).C.CO\\ \|\\ C_6H_4(NH_2).C.CO\end{matrix}\!>O$. [280°]. Formed by reduction of the nitro compound (Reimer, *B.* 14, 1802). Small plates. Insol. most solvents.

Di-p-amido-di-phenyl-ethylene-di-sulphonic acid $C_2H_2(C_6H_3(NH_2)SO_3H)_2$. *Di-amido-stilbene-di-sulphonic-acid.* Obtained by reduction with zinc-dust of the brown product (azoxy- or azo-di-phenyl-ethylene-di-sulphonic acid?) which is formed by boiling *p*-nitro-toluene-*o*-sulphonic acid $C_6H_3Me(NH_2)SO_3H$ [1:4:2:] with aqueous NaOH. Microscopic needles. Nearly insol. water. Its salts are easily soluble. By nitrous acid it is converted into a tetrazo-compound which by combination with amines or phenols gives colouring-matters which have the property of dyeing cotton from a soap bath (Bender a. Schultz, *B.* 19, 3234).

o-AMIDO-PHENYL-GLYOXYLIC ACID *v.* ISATIC ACID.

m-Amido-phenyl-glyoxylic acid $C_8H_7NO_3$ *i.e* $C_6H_4(NH_2)CO.CO_2H$ [1:3]. Colourless prisms or needles. [270°–280° with decomposition]. Prepared by reduction of *m*-nitro-phenyl-glyoxylic acid with alkaline $FeSO_4$.

Salts.—A'Ag: sparingly soluble crystalline powder.—$C_8H_7NO_3.HCl$: soluble flat prisms (Claisen a. Thompson, *B.* 12, 1946).

p-AMIDO-s-DI-PHENYL-GUANIDINE m-CARBOXYLIC ACID $C_{14}H_{14}N_4O_2$ *i.e.* [1:4] $NH_2.C_6H_4.NH.C(NH).NH.C_6H_4.CO_2H$. *Amido-phenyl-benzglycocyamine.* Prepared by heating cyano-carbimido-amido-benzoic acid (*v.* p. 157) with *p*-phenylene-diamine (Griess, *B.* 16, 338). Small prisms. Salt.—$B''H_2Cl_2$.

p-amido-s-di-phenyl-guanidine o-carboxylic acid. *Anhydride* $H_2N.C_6H_4.NH.C\left\langle\begin{matrix}NH.C_6H_4\\ N - CO\end{matrix}\right\rangle$ *Amido-phenyl-benzglycocyamidine.* Formed by boiling di-cyano-amido-benzoyl (*v.* p. 155) with an aqueous solution of *p*-phenylene-diamine (Griess, *B.* 18, 2421). Very small white needles; v. sol. hot water, m. sol. alcohol.

AMIDO-PHENYL-HYDROXIDE *v.* AMIDO-PHENOL.

m-AMIDO-PHENYL-HYDRAZINE $C_6H_9N_3$ *i.e.* $C_6H_4(NH_2).NH.NH_2$ Formed by saponification of the oxamic acid $C_6H_4(NH.C_2O_2.OH).NH.NH_2$ which is obtained by reduction of *m*-diazo-phenyl-oxamic acid $C_6H_4(NH.C_2O_2.OH).N_2Cl$ with $SnCl_2$ (Griess, *B.* 18, 964). V. sol. alcohol and ether, sl. sol. water. Very oxidisable.

Amido-phenyl-hydrazine sulphonic acid $C_6H_3(NH_2)(N_2H_3)(SO_3H)$ [3:1:6]. Formed by reduction of nitro-phenyl-hydrazine sulphonic acid with NH_4HS or $SnCl_2$ (Limpricht, *B.* 18, 2194). Very soluble in water. Salts:—A'H,HCl easily soluble fine white needles.—$A'HH_2SO_4$: microscopic needles.—*A'H,HNO_3: prisms.

AMIDO-DI-PHENYL-KETONE *v.* AMIDO-BENZOPHENONE.

o-AMIDO-PHENYL-MERCAPTAN C_6H_7NS *i.e.* $C_6H_4(NH_2)(SH)$. *Amido-phenyl-sulphydrate.* [26°]. (234°).

Formation.—1. By fusing benzenyl-amido-phenyl-mercaptan (*q. v.*) with potash (Hofmann, *B.* 12, 2363).—2. Anhydro-oxalyl-amido-phenyl-mercaptan (easily prepared from acetanilide and sulphur) is fused with potash (3 pts.). The yield is nearly theoretical (Hofmann, *B.* 13, 1230). Colourless needles, very easily oxidised. It forms products of condensation with acids, aldehydes, and nitriles; thus acetic acid, acetyl chloride, acetonitrile, and aldehyde each produce ethenyl-amido-phenyl mercaptan (*q. v.*) $C_6H_4\left\langle\begin{matrix}N\\ S\end{matrix}\right\rangle C.CH_3$.

p-Amido-diphenyl-mercaptan [1:4] $H_2N.C_6H_4.C_6H_4.SH$ [1:4]. Prepared by reducing *p*-nitro-diphenyl sulphochloride with tin and HCl (Gabriel a. Damberger, *B.* 13, 1410).

Salt.—B'HCl: small glittering prisms.

AMIDO-PHENYL-METHANE *v.* Toluidine

***m*-Amido-di-phenyl-methane** $C_{13}H_{13}N$ *i.e.* $C_6H_5.CH_2.C_6H_4.NH_2$. [46°]. Formed by reducing *m*-nitro-di-phenyl-methane (Becker, *B.* 15, 2092).

Acetyl derivative. [91°]: pearly plates.

***p*-Amido-di-phenyl-methane.** [35°]. Formed by reducing *p*-nitro-di-phenyl methane with tin and HCl (Basler, *B.* 16, 2718). The sulphate is sl. sol. cold water.

di-amido-di-phenyl-methane $C_{13}H_{10}(NH_2)_2$. [85°]. Formed by reducing (*a*)-di-nitro-di-phenyl-methane (Doer, *B.* 5, 795). Pearly plates; sl. sol. water (Praetorius, *A.* 194, 348). The sulphate is v. sl. sol. water.

Tetra-amido-di-phenyl-methane $C_{13}H_8(NH_2)_4$. [161°]. By reduction of the nitro compound [172°] (Staedel, *A.* 218, 341). White needles (from benzene). M. sol. water, sl. sol. benzene.

Acetyl derivative $C_{13}H_8(NHAc)_4$. Crystalline powder. V. sl. sol. water; m. sol. alcohol.

Amido-tri-phenyl-methane $C_{19}H_{17}N$ *i.e.* $CHPh_2.C_6H_4.NH_2$. [84°]. Prepared by heating aniline hydrochloride with di-phenyl-carbinol and $ZnCl_2$ at 180° (Fischer a. Roser, *B.* 13, 674; *A.* 206, 155). Prisms or plates. Is a weak base. The benzene compound ($C_{19}H_{17}NC_6H_6$) forms long colourless needles. Salts.—B'HCl: needles, sl. sol. water.—$B'H_2PtCl_6$.

Di-amido-tri-phenyl-methane $C_{19}H_{18}N_2$ *i.e.* $C_6H_5.CH(C_6H_4NH_2)_2$. [139°].

Formation.—1. From benzylidene chloride, aniline, and zinc dust (Böttinger, *B.* 12, 976).—2. From di-amido-tri-phenyl-carbinol by reducing with zinc dust (Doebner, *A.* 217, 246; *B.* 15, 236).—3. By heating aniline hydrochloride with benzoic aldehyde and fuming HCl (Mazzara, *G.* 14, 510).

Preparation.—A mixture of benzaldehyde (10 pts.), aniline sulphate (28 pts.), $ZnCl_2$ (20 pts.) and a little water, is heated on a water bath for several hours, the fused mass is boiled with dilute H_2SO_4, diluted, filtered, and the base precipitated with NH_3; yield 80 p.c. of the theoretical (Fischer, *B.* 15, 676).

Properties.—Colourless crystals (from ether) [139°]. Prisms containing benzene of crystallisation (from benzene) [106°]; at 120° the benzene goes off. V. sl. sol. water, sol. alcohol or ether.

Additional References.—C. Böttinger, *B.* 11, 276, 840; 13, 958; O. Fischer, *A.* 206, 147, 153; *B.* 13, 665.

Tri-amido-tri-phenyl-methane $C_{19}H_{19}N_3$ *i.e.* $CH(C_6H_4.NH_2[1:4])_3$. *Para-leucaniline.* [148°].

Formation.—1. By reducing tri-nitro-tri-phenyl-methane with zinc dust and glacial acetic acid (O. a. E. Fischer, *A.* 194, 272).—2. By [illegible]ucing para-rosaniline (Hofmann, *Pr.* 12, 9).—3. By reducing nitro-di-amido-tri-phenyl-methane, prepared from aniline hydrochloride, *p*-nitro-benzoic aldehyde and $ZnCl_2$ (Fischer a. Greiff, *B.* 13, 670; Fischer, *B.* 15, 678).

Properties.—Colourless plates. Readily converted by oxidation into para-Rosaniline (*q. v.*).

Salts.—$B'''H_3Cl_3aq$: short prisms, sl. sol. alcohol, ether, and HClAq.—The sulphate forms needles, v. sol. water, sl. sol. alcohol, insol. ether.—The oxalate forms prisms, v. sol. water.—The platinochloride forms sparingly soluble short needles.

Tri-acetyl derivative [177°]. Thin tables; when oxidised by $K_2Cr_2O_7$ and acetic acid it gives tetra-acetyl-para-rosaniline.

Tri-benzoyl derivative [149°]. Colourless needles; sol. alcohol, v. sl. sol. water, ether, and benzene (Renouf, *B.* 16, 1301).

***m-p-p*-Tri-amido-tri-phenyl-methane** [1:3] $H_2N.C_6H_4.CH(C_6H_4.NH_2[1:4])_2$. *Pseudo-leucaniline.* [150°]. Obtained by reducing *m*-nitro-di-*p*-amido-tri-phenyl-methane (Fischer, *B.* 13, 673). Colourless crystals; sol. alcohol, sl. sol. ether or benzoline. Crystallises with benzene in white needles of $C_{19}H_{19}N_3C_6H_6$ [145°]. Gives, on oxidation, a violet colouring-matter.

Salts.—$B_2'''3H_2PtCl_6$: yellow crystalline pp., v. sol. water, m. sol. alcohol.

***o-p-p*-tri-amido-tri-phenyl-methane** [1:2] $H_2N.C_6H_4.CH(C_6H_4NH_2[1:4])_2$. [165°]. Formed by reduction of the *o*-nitro-di-*p*-amido-tri-phenyl-methane obtained by heating *o*-nitro-benzoic aldehyde with aniline sulphate and $ZnCl_2$. Small crystals. On oxidation it gives a brown colouring matter.

Salts.—$B'''H_3Cl_3$: colourless easily soluble needles. The sulphate forms small quadratic tables, v. sol. water, sl. sol. alcohol. The oxalate forms small soluble needles (Renouf, *B.* 16, 1304).

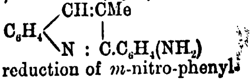
AMIDO-PHENYL METHYL KETONE *v.* Amido-acetophenone.

***p*-AMIDO-DI-PHENYL-METHYL-PYRAZOL-CARBOXYLIC ACID** $C_{17}H_{15}N_3O_2$ *i.e.*

$$\begin{array}{l}\qquad\qquad N\text{———}NPh\\ \qquad\qquad \| \qquad\qquad |\\ C_6H_4(NH_2).C.C(CO_2H):CMe\end{array}$$

[251°]. Formed by reduction of *p*-nitro-di-phenyl-methyl-pyrazol-carboxylic acid with $SnCl_2$ (Knorr a. Jödicke, *B.* 18, 2259). Crystalline powder. Sol. alcohol, ether, acids, and alkalis, insol. water. It evolves CO_2 at its melting-point.

***m*-AMIDO-(*Py.* 3)-PHENYL-(*Py.* 2)-METHYL QUINOLINE** $C_{16}H_{14}N_2$ *i.e.*

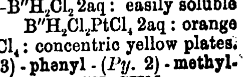


$$C_6H_4\left\langle\begin{array}{l}CH{:}CMe\\ \qquad |\\ N : C.C_6H_4(NH_2)\end{array}\right.$$

[115]. Obtained by reduction of *m*-nitro-phenyl-methyl-quinoline with tin and HCl (Miller a. Kinkelin, *B.* 19, 533). Prisms. Very soluble in alcohol and benzene, tolerably in ether. Has no dyeing power, although it is isomeric with flavaniline. By further reduction with tin and HCl it yields a tetrahydride.

Salts.—The mono-acid salts are yellow, the di-acid colourless.—$B''H_2Cl_2\,2aq$: easily soluble glistening prisms. $B''H_2Cl_2PtCl_4\,2aq$: orange tables.—$B''H_2Cl_2PtCl_4$: concentric yellow plates.

***m*-Amido-(*Py.* 3)-phenyl-(*Py.* 2)-methyl-tetrahydro-quinoline**



$$C_6H_4\left\langle\begin{array}{l}CH_2.CHMe\\ \qquad |\\ NH.CH.C_6H_4(NH_2)\end{array}\right.$$

Formed by reduction of amido-phenyl-methyl-quinoline with tin and HCl.

Di-acetyl derivative $C_{16}H_{16}N_2Ac_2$. [178°]. Thin colourless prisms; sol. hot alcohol.

***p*-Amido-(Py. 3)-phenyl-(Py. 1)-methyl-quinoline** *v.* Flavaniline.

AMIDO-PHENYL-HYDRO-QUINOLINE *v.* Amido-phenyl-quinoline.

***p*-AMIDO-PHENYL-OCTANE** $C_{14}H_{23}N$ *i.e.* $H_2N.C_6H_4.C_8H_{17}$. *Capryl-phenyl-amine. Phen-capryl-amine.* (291° corr.). Formed by heating a mixture of aniline, capryl alcohol, and $ZnCl_2$ at 280°. Or by heating aniline hydrochloride and capryl alcohol at 200°–290° (Beran, *B.* 18, 139). Fluid at −20°. Colourless oil.

Salts.—$B'_2H_2SO_4$: v. sol. hot water, v. sl. sol. cold.—$B'_2H_2C_2O_4$: small plates, v. sol. alcohol and hot water, sl. sol. cold water.

Benzoyl derivative $C_{14}H_{21}.NHBz$. [109°]. Slender felted needles, v. sol. alcohol and ether when hot, sl. sol. when cold.

o-**Amido-phenyl-octane.** From the nitro-compound (Ahrens, *B.* 19, 2725).—$B'_2H_2SnCl_6$.

p-**Amido-ω-phenyl-*n*-octane.** [19·5°]. (311° cor.). From *n*-octyl alcohol, aniline, and $ZnCl_2$ (B.).—B'HCl.—$B'_2H_2SO_4$.—$B'_2H_2C_2O_4$.

Formyl derivative. [56°].

Acetyl derivative. [93°].

Benzoyl derivative. [117°].

AMIDO-OPIANIC ACID $C_{10}H_{11}NO_5$ *i.e.* $C_6H(OMe)_2(NH_2)(CHO)(CO_2H)$ [6:5:3:2:1]. *Di-methoxy-amido-aldehydo-benzoic acid.* From nitroso-opianic acid, $SnCl_2$, and HCl. Crystalline. **Salt.**—HA'HCl: needles, decomposed by water.

Reactions.—1. *Baryta-water* give a blue-violet colour.—2. Fe_2Cl_6 gives a green colour in solutions of NH_4A'.—3. Hot Ac_2O gives granules of $C_{24}H_{24}N_2O_{11}$ [233°] (Kleemann, *B.* 20, 876).

DI-AMIDO-DI-PHENYL OXIDE $C_{12}H_{12}N_2O$ *i.e.* $(C_6H_4.NH_2)_2O$. [185°]. From the nitro compound (Hoffmeister, *A.* 159, 208). The **sulphate** forms slender needles.

AMIDO-PHENYL-PENTANE *v.* Amido-amyl-benzene.

TRI-AMIDO-TRI-PHENYL-PHOSPHINE OXIDE $C_{18}H_{18}N_3PO$ *i.e.* $OP(C_6H_4.NH_2)_3$. [259°]. Obtained by reduction of tri-nitro-tri-phenyl-phosphine-oxide (Michaelis a. Soden, *B.* 17, 923). White prisms. Soluble in hot water, hot alcohol, and acetone, sparingly in cold water, cold alcohol, and ether. Its salts are very soluble in water.

Tri-acetyl derivative $OP(C_6H_4.NHAc)_3aq$. [188°], colourless crystals.

Tri-benzoyl derivative $OP(C_6H_4.NHBz)_3$ [c. 180°], crystalline powder.

DI-AMIDO-DIPHENYL-PHTHALIDE

$$C_{20}H_{16}N_2O_2 \text{ i.e. } C_6H_4\left<\begin{matrix}C{=}(C_6H_4NH_2)_2\\ \quad\;\;>O\\ C{=}O\end{matrix}\right.$$

Lactone of di-amido-tri-phenyl-carbinol carboxylic acid. [180°]. Tables. Prepared by reduction of dinitro-diphenyl-phthalide. By the action of HNO_2 it gives phenol-phthaleïn (Baeyer, *B.* 12, 642; *A.* 202, 66).

AMIDO-PHENYL-PIPERIDINE $C_{11}H_{16}N_2$ *i.e.* $C_5NH_{10}.C_6H_4.NH_2$. [40°]. Formed by reduction of the corresponding nitro-compound [105°] with $SnCl_2$ and HCl.—$B''H_2Cl_2aq$: large colourless crystals (Lellmann, *B.* 20, 681).

p-**AMIDO-β-PHENYL-PROPANE** $C_9H_{13}N$ *i.e.* $H_2N.C_6H_4.CH_2.CH_2.CH_3$. *Amido-propyl-benzene. Propyl-phenyl-amine. Phenpropylamine.* (225°). From aniline, $ZnCl_2$, and propyl alcohol at 270° (Louis, *B.* 16, 105; Francksen, *B.* 17, 1220). Liquid, volatile with steam; v. sl. sol. water. **Salts**: B'HCl: laminæ, [204°].—$^{x}B'_2H_2PtCl_6$.—B'HBr. [213°].—B'HI.—$B'_2H_2SO_4$: laminæ, sl. sol. cold water.—$B'_2H_2C_2O_4$: sl. sol. cold water.

Acetyl derivative $C_9H_{12}AcN$. [87°].

Benzoyl derivative $C_9H_{12}BzN$. [115°].

p-**Amido-α-phenyl-propane** $H_2N.C_6H_4.CH(CH_3).CH_3$. *Amido-isopropyl-benzene* (217°). Similarly prepared from iso-propyl alcohol (L.). Liquid, sl. sol. water. **Salts**: $B'_2H_2SO_4$: sl. sol. cold water.—$B'_2H_2C_2O_4$.

Benzoyl derivative [115°]: laminæ.

See also Cumidine and Phenyl-propylamine.

o-**AMIDO-PHENYL-PROPIOLIC ACID** $C_9H_7NO_2$ *i.e.* $C_6H_4(NH_2).C{:}C.CO_2H$.

Preparation.—An ammoniacal solution of *o*-nitro-phenyl-propiolic acid is slowly added to a cold solution of $FeSO_4$ (11 pts.) saturated with NH_3; after 1 or 2 hours' standing the mixture is filtered and the amido-acid ppd. from the filtrate by adding HCl in slight excess; yield: 65 p.c. of the nitro-acid used (Richter, *B.* 16, 679).

Properties.—Microscopic needles. Soluble in alcohol, sparingly in ether, nearly insoluble in water, benzene, chloroform, and ligroine. Dissolves in aqueous acids. Decomposes on heating to about 125° and on boiling with water, in the latter case forming *o*-amido-acetophenone and CO_2. By boiling with NaOH and then adding HCl a splendid red colour is produced.

Salt.—$A'Ag^{x}$: insoluble pp.

Ethyl ether A'Et—[55°] needles (Baeyer a. Bloem, *B.* 15, 2147).

α-AMIDO-α-PHENYL-PROPIONIC ACID $C_9H_{11}NO_2$ *i.e.* $CH_3.C(C_6H_5)(NH_2).CO_2H$. *Amido-hydro-atropic acid.* From the nitrile by treatment with HCl (Tiemann a. Köhler, *B.* 14, 1981). Feather-like, satiny, needles. Sublimes about 260°. V. e. sol. water, insol. alcohol and ether. Converted by nitrous acid into atrolactic acid.

Nitrile $CH_3.CPh.(NH_2).CN$. Yellow oil.

β-Amido-α-phenyl-propionic acid $CH_2(NH_2).CH(C_6H_5).CO_2H$. [169·5°]. A product of action of conc. NH_3Aq on β-bromo-α-phenyl-propionic acid (Fittig a. Wurster, *A.* 195, 158; Merling, *A.* 209, 11). Plates (from water). Sl. sol. cold water.

o-**Amido-α-phenyl-propionic acid.** *Anhydride* or *lactam* $C_6H_4{<}\begin{matrix}NH\\CHMe\end{matrix}{>}CO$. [119°]. *Atroxindol.* Formed, instead of the acid, by reducing $C_6H_4(NO_2).CHMe.CO_2H$. Needles (from dilute HCl). Sl. sol. cold water, forming a neutral solution; sol. alcohol and ether. When quite pure it has a pleasant smell. Slightly volatile with steam. It dissolves in alkalis but is reppd. by CO_2 (Trinius, *A.* 227, 274).

p-**Amido-α-phenyl-propionic acid** $CH_3.CH(C_6H_4NH_2).CO_2H$. [128°]. From nitro-hydro-atropic acid, Sn and HCl (Trinius, *A.* 227, 267). **Salt.**—HA'HCl; needles; v. sol. water.

α-Amido-β-phenyl-propionic acid $C_9H_{11}NO_2$ *i.e.* $C_6H_5.CH_2.CH(NH_2)CO_2H$.

Amido-hydro-cinnamic acid.

Occurrence.—In the radicles of germinating lupin seeds, together with other amido-acids. Forms about 1 p.c. of the dry seed. The mixture is heated with cupric hydrate and filtered, the acid is isolated from the residue by treatment with H_2S and subsequent evaporation (Schulze a. Barbieri, *J. pr.* [2] 27, 342; *B.* 14, 1785).

Formation.—From its nitrile by HCl (Erlenmeyer a. Lipp, *A.* 219, 194). The acid formed in this way is perhaps not identical with that in lupin seeds. An amido-phenyl-propionic acid identical with that in lupin seeds occurs among the products of the decomposition of proteïds by HCl. It melts at [275°–280°] and is optically active, while the acid from phenyl-acetic aldehyde melts at [263°-265°] and is inactive (Schulze a. Nägeli, *H.* 11, 201).

Properties.—Glittering, anhydrous, plates (from hot saturated solutions); groups of slender needles, containing aq (from dilute solutions) (S. a. B.). Satiny plates (from alcohol); short anhydrous prisms or stars (from water) (E. a. L.). Sweet taste. Neutral reaction. M. sol. water, v. sl. sol. alcohol, insol. ether. Small quantities may be sublimed. Gives no colour with Millon's reagent.

Salts.—CuA'_2: insol. water (S. a. B.).—$CuA'_2 2aq$: rosettes of small blue prisms (E. a. L.).—AgA'.—HA'HCl: prisms or stars; v. sol. alcohol or water, insol. conc. HCl.—$(HA'HCl)_2PtCl_4$.—$HA'HNO_3$.—$(HA')_2H_2SO_4$.

Reactions.—1. With $K_2Cr_2O_7$ and H_2SO_4 gives off odour of benzoic aldehyde, and ultimately forms benzoic acid.—2. When heated it cakes together and at about 270° it melts giving off CO_2, H_2O, and exo-amido-phenyl-ethane (*q. v.*); the residue may be crystallised from alcohol, it melts at [280°] and has the formula C_8H_9NO. From the behaviour of the analogous amido-propionic acid, we may suppose this body to be phenyl-lactimide.—3. By putrefaction it gives phenyl acetic acid.

Nitrile $C_6H_5.CH_2.CH(NH_2).CN$. From the compound of HCN with phenyl-acetic aldehyde by heating with alcoholic NH_3 at 100° (Erlenmeyer a. Lipp, *A.* 219, 189). Small crystals.

Salts.—B'HCl: trimetric prisms; v. sol. alcohol, insol. ether, v. e. sol. water.

Anhydride or *lactam* C_9H_9NO or

$C_{18}H_{18}N_2O_2$ *i.e.* $\mathrm{Ph.CH_2.CH}\left\langle\begin{matrix}\mathrm{NH}\\ \mathrm{CO}\end{matrix}\right\rangle$ or

$\mathrm{Ph.CH_2.CH}\left\langle\begin{matrix}\mathrm{NH.CO}\\ \mathrm{CO.NH}\end{matrix}\right\rangle\mathrm{CH.CH_2Ph}$.

Phenyl-lactimide. [291°]. A by-product in the conversion of the acid into amido-phenyl-ethane by the action of heat. Very slender silky needles (from alcohol) forming an electric powder. May be sublimed as woolly needles. V. sl. sol. water, HCl, or KOHAq; insol. ether; sl. sol. glacial acetic acid.

β-Amido-β-phenyl-propionic acid $C_6H_5.CH(NH_2).CH_2.CO_2H$.

β-Amido-hydro-cinnamic acid. [121°]. From β-bromo-β-phenyl-propionic acid and conc. aqueous NH_3 at 0° (Posen, *A.* 195, 144; 200, 97). Large monoclinic crystals (from water); m. sol. cold water, v. sol. alcohol, v. sl. sol. ether. Boiling HClAq splits it up into NH_3 and cinnamic acid. Salt.—B'HCl; prisms, v. sol. water.

Anhydride or *lactam*

$\mathrm{C_6H_5.CH}\left\langle\begin{matrix}\mathrm{CH_2}\\ \mathrm{NH}\end{matrix}\right\rangle\mathrm{CO}$. *Phenyl-lactimide.* [147°].

Formed, instead of a sulphate, when the acid is added to H_2SO_4 (1 vol.) diluted with water (1 vol.). Needles, insol. cold water, m. sol. hot water, alcohol, or ether. Is not reconverted into the amido acid by prolonged boiling with water.

***o*-Amido-β-phenyl-propionic acid**

Anhydride or *lactam* C_9H_9NO *i.e.*

$\mathrm{C_6H_4}\left\langle\begin{matrix}\mathrm{NH\,.\,CO}\\ \mathrm{CH_2.CH_2}\end{matrix}\right\rangle$ or $\mathrm{C_6H_4}\left\langle\begin{matrix}\mathrm{N{:}C(OH)}\\ \mathrm{CH_2.CH_2}\end{matrix}\right\rangle$.

Hydro-carbostyril. *Di-hydro-(Py. 3)-oxy-quinoline.* [160°]. Formed, instead of the amido acid, when *o*-nitro-β-phenyl-propionic acid is reduced by tin and HCl (Glaser a. Buchanan, *Z.* 1869, 194). Prisms; v. sl. sol. water v. sol. alcohol, ether, and warm conc. HClAq. May be distilled. PCl_5 at 140° converts it into di-chloro-quinoline.

Ethyl derivative $C_9H_8N(OEt)$. [199°]. Formed by reducing the ethyl derivative of carbostyril with sodium amalgam (Friedländer a. Ostermayer, *B.* 15, 335). Silvery plates.

***m*-Amido-β-phenyl-propionic acid** $C_6H_4(NH_2).CH_2.CH_2.CO_2H$. *m-Amido-hydro-cinnamic acid.* [85°]. Formed by reduction of *m*-nitro-β-phenyl-propionic acid with tin and HCl (Gabriel, *B.* 15, 846). Colourless crystals. V. sol. water, alcohol, and ether. Salt.—A'HHCl: colourless needles or scales.

***p*-Amido-β-phenyl-propionic acid** $C_6H_4(NH_2).CH_2.CH_2.CO_2H$. *p-Amido-hydro-cinnamic acid.* [131°] (Glaser a. Buchanan, *Z.* 1869, 195). Prepared by reduction of *p*-nitro-phenyl-propionic acid with $FeSO_4$ and NH_3. Salts.—B'HCl.—$B'_2H_2SO_4$.

Acetyl derivative $C_6H_4(NHAc)C_2H_4.CO_2H$. [143°]. Long colourless needles or short prisms. Sol. alcohol and ether, insol. CS_2 (Gabriel, *B.* 15, 843).

α-β-di-amido-β-phenyl-propionic acid.

Anhydride or *lactam*

$$\begin{matrix}\mathrm{C_6H_5.CH.CH(NH_2).CO}\\ \mathrm{NH}\text{———————}\end{matrix}\;.$$

α-Benzoyl derivative

$\begin{matrix}\mathrm{C_6H_5.CH.CH(NHBz).CO}\\ \mathrm{NH}\text{————————}\end{matrix}$. [187°]. Formed by heating benzoyl-imido-cinnamic acid,

$\begin{matrix}\mathrm{C_6H_5.CH.CH.CO_2H}\\ \diagdown\diagup\\ \mathrm{NBz}\end{matrix}$, with strong aqueous NH_3.

Glistening needles or prisms; sol. hot alcohol and acetic acid, sl. sol. ether, insol. water, dilute acids and alkalis. By boiling with HCl it loses NH_3 giving the benzoyl derivative of α-amido-cinnamic acid (Plöchl, *B.* 17, 1616).

α-*p*-di-amido-β-phenyl-propionic acid $C_9H_{12}N_2O_2aq$ *i.e.* $C_6H_4(NH_2)CH_2.CH(NH_2)CO_2Haq$ [245°-250°]. *p-Amido-phenyl-alanine.* Got by reducing *p*-nitro-α-amido-phenyl-propionic acid (Erlenmeyer a. Lipp, *A.* 219, 219), or by reducing α-*p*-di-nitro-cinnamic ether and saponifying the product (Friedländer a. Mühly, *B.* 16, 852; *A.* 229, 226). Silky needles (from water), sl. sol. alcohol, insol. ether. Neutral; has a sweet taste. Reduces salts of gold and silver. Does not give Hoffmann's mercury reaction (*A.* 87, 124). Gives off no NH_3 when boiled with KOH. Converted by nitrous acid into tyrosine.

Salts.—HA'2HCl.—$HA'H_2PtCl_6$.—CuA'_2; small violet-blue crystals, sl. sol. water.—$HA'H_2SO_4$: small needles.

(4,2,1)-di-amido-β-phenyl-propionic acid (4:2:1), $C_6H_3(NH_2)_2.CH_2.CH_2.CO_2H$.

Anhydride or *lactam* $C_9H_{10}N_2O$ *i.e.*

$\mathrm{H_2N.C_6H_3}\left\langle\begin{matrix}\mathrm{CH_2.CH_2}\\ \mathrm{NH\,.\,CO}\end{matrix}\right\rangle$. *Amido-hydro-carbostyril.* (*Py.* 3)-*oxy*-(*B.* 3)-*amido-di-hydro-quinoline.* [211°]. Formed by reducing (4,2,1)-di-nitro-β-phenyl-propionic acid (Gabriel a. Zimmermann, *B.* 12, 602). Needles or prisms. Not affected by boiling alkalis. Salt.—B'HCl.

(1:3:1)-Di-amido-β-phenyl-propionic acid. [4:3:1] $C_6H_3(NH_2)_2.CH_2.CH_2.CO_2H$. *Di-amido-hydro-cinnamic acid.* [144°, dry]. Formed by reduction of *m*-nitro-*p*-amido-phenyl-propionic

acid with tin and HCl (Gabriel, *B.* 15, 2291). Thick crystals containing aq. Sol. alcohol and acetic acid, v. sl. sol. ether, chloroform, benzene, and CS$_2$. Dissolves in aqueous acids and alkalis.

m-AMIDO-(*Py.* 3)-PHENYL-QUINOLINE

$$C_{15}H_{12}N_2 \textit{ i.e. } C_6H_4\left\langle\begin{array}{l}CH{:}CH\\ \quad\;\; |\\ N : C.C_6H_4(NH_2)\end{array}\right. . \quad [120°].$$

Formed by reduction of *m*-nitro-phenyl-quinoline with tin and HCl (Miller a. Kinkelin, *B.* 18, 1904). Long glistening needles. Distils at a high temperature undecomposed. Sol. ether, benzene, and hot water, v. sl. sol. cold water.

Salts.—B''H$_2$Cl$_2$: easily soluble colourless needles.—B''H$_2$Cl$_2$PtCl$_4$: yellow crystalline powder. — B''$_2$H$_2$Cl$_2$PtCl$_4$: long fine needles. — B''H$_2$SO$_4$2aq: thick colourless prisms.

(*a*)-Amido-(*Py.* 1)-phenyl-quinoline

$$C_{15}H_{12}N_2 \textit{ i.e. } C_6H_4\left\langle\begin{array}{l}C(C_6H_4.NH_2){:}CH\\ \qquad\qquad\quad\;\; |\\ N\!=\!=\!=\!=\!=\!=\!=CH\end{array}\right. . \quad [150°].$$

Obtained by reduction of the corresponding nitro-compound [187°] with SnCl$_2$. Colourless glistening plates (from alcohol). V. e. sol. alcohol, benzene, and chloroform, v. sl. sol. ether with a bluish-violet fluorescence. Volatilises undecomposed. Its mono-acid salts have a deep yellow colour and dye wool yellow, the di-acid salts are colourless.—*B''HI: soluble yellow needles.—*B''$_2$H$_2$Cl$_2$PtCl$_4$: yellow prismatic needles. The chromate is a sparingly soluble brown pp. (Kœnigs a. Nef, *B.* 20, 627).

(*β*)-Amido-(*Py.* 1)-phenyl-quinoline

$$C_{15}H_{12}N_2 \textit{ i.e. } C_6H_4\left\langle\begin{array}{l}C(C_6H_4.NH_2){:}CH\\ \qquad\qquad\quad\;\; |\\ N\!=\!=\!=\!=\!=\!=\!=CH\end{array}\right. . \quad [198°].$$

Obtained by reduction of the corresponding nitro-compound [118°] with SnCl$_2$. Four-sided prisms. Sl. sol. alcohol and benzene, v. sol. chloroform, v. sl. sol. ether. The ethereal solution has a bluish-violet fluorescence. It volatilises undecomposed. Its mono-acid salts have a yellow colour and dye wool yellow, the di-acid salts are colourless.—*B''H$_2$Cl$_2$PtCl$_4$: yellow prisms, sol. HCl, nearly insol. water (Kœnigs a. Nef, *B.* 20, 628).

Amido-phenyl-quinoline. [136·5°]. V.D. 7·67 (for 7·62). Obtained by heating quinoline hydrochloride with aniline (Jellinek, *M.* 7, 351). Yellowish white needles; insol. cold water, sol. benzene, alcohol, and chloroform.

Salts.—B''2HCl.—B''H$_2$PtCl$_6$.

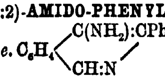
Methylo-iodide. B''MeI. [220°].

***m*-Amido-(*Py.* 3)-phenyl-hydroquinoline**

$$C_6H_4\left\langle\begin{array}{l}CH_2.CH_2\\ \quad\;\; |\\ NH.CH.C_6H_4(NH_2)\end{array}\right. . \quad \text{Thick syrup.}$$

Formed by reduction of *m*-amido-phenyl-quinoline or of *m*-nitro-phenyl-hydroquinoline with tin and HCl (Miller a. Kinkelin, *B.* 18, 1907).—B''H$_2$Cl$_2$: monoclinic tables.

(*Py.* 1:2)-AMIDO-PHENYL-ISOQUINOLINE



$$C_{15}H_{12}N_2 \textit{ i.e. } C_6H_4\left\langle\begin{array}{l}C(NH_2){:}CPh\\ \qquad\quad\;\; /\\ CH{:}N\end{array}\right. . \quad [c.\ 100°].$$

Formed by reduction of (*Py.* 4:1:2)-chloro-nitro-phenyl-isoquinoline by heating with HI and P (Gabriel, *B.* 19, 834). Yellowish plates or needles. Easily soluble in ordinary solvents, moderately in ether and ligroine. Dissolves readily in acids. Salts.—B'HI: yellow crystals.—B'$_2$H$_2$Cl$_2$PtCl$_4$: long orange-red needles. —B'HCl*: flat needles.

DI-AMIDO-DI-PHENYL SULPHIDE

C$_{12}$H$_{12}$N$_2$S *i.e.* (C$_6$H$_4$NH$_2$)$_2$S. *Thioaniline.* [105°]. Mol. w. 216. Obtained by heating aniline (6 pts.) with sulphur (1 pt.) at 160°, with gradual addition of PbO (Merz a. Weith, *B.* 4, 384); or from di-phenyl sulphide by nitration and reduction (Krafft, *B.* 7, 384). A small quantity is got by the action of S$_2$Cl$_2$ on aniline (Schmidt, *B.* 11, 1168). Long thin needles (from water). V. sl. sol. cold water, sl. sol. hot water, v. sol. alcohol, ether, and hot benzene. Not attacked by hot conc. HCl, by hot alcoholic KOH, or by sodium-amalgam. Its solutions give a blue colour when warmed with Fe$_2$Cl$_6$. Conc. H$_2$SO$_4$ dissolves it with violet colour.

Salts.—B''H$_2$Cl$_2$2aq: prisms, v. sol. water, sl. sol. alcohol or cold conc. HCl.—B''HCl2aq.—B''H$_2$PtCl$_6$. — B''H$_2$SO$_4$aq. — B''$_2$H$_2$SO$_4$aq. — B''H$_2$C$_2$O$_4$.

Diacetyl derivative (C$_6$H$_4$NAcH)$_2$S. [215°]. Needles.

Di-*o*-amido-di-phenyl di-sulphide C$_{12}$H$_{12}$N$_2$S$_2$ *i.e.* (C$_6$H$_4$NH$_2$)$_2$S$_2$. [93°]. Prepared by oxidising *o*-amido-phenyl mercaptan with Fe$_2$Cl$_6$ (Hofmann, *B.* 12, 2363). Plates; insol. water, sol. alcohol. Readily reduced back to the mercaptan. The hydrochloride forms laminæ, sl. sol. HClAq.

Di-*p*-amido-di-phenyl di-sulphide (C$_6$H$_4$NH$_2$)$_2$S$_2$. [79°]. Formed by saponifying its acetyl derivative with dilute H$_2$SO$_4$. Long greenish needles (from water); v. sl. sol. water, v. sol. alcohol.

Salts.—B''H$_2$SO$_4$2aq: small needles.

Di-acetyl derivative (C$_6$H$_4$NAcH)$_2$S$_2$. [c. 217°]. Formed, together with the diacetyl derivative of di-amido-di-phenyl tri-sulphide, by heating acetanilide with S$_2$Cl$_2$ at 100° (Schmidt, *B.* 11, 1171).

Di-amido-di-phenyl tri-sulphide. *Di-acetyl derivative* (C$_6$H$_4$NAcH)$_2$S$_3$. [214°]. Prepared as described above; forms laminæ (from glacial acetic acid).

AMIDO-DI-PHENYL SULPHONE

C$_{12}$H$_{11}$NSO$_2$ *i.e.* C$_6$H$_5$.SO$_2$.C$_6$H$_4$.NH$_2$. *Amido-sulphobenzide.* From nitro-di-phenyl sulphone by alcoholic ammonium sulphide (Gericke, *A.* 100, 209). Minute prisms, sl. sol. cold water.

Salts.—B'HCl: [c. 90]; reddish four-sided prisms.—B'$_2$H$_2$PtCl$_6$.

Di-amido-di-phenyl sulphone C$_{12}$H$_{12}$N$_2$SO$_2$ *i.e.* (C$_6$H$_4$NH$_2$)$_2$SO$_2$. [168°] (Schmid a. Nölting, *B.* 9, 80). Obtained in the same way from di-nitro-di-phenyl sulphone. Four-sided prisms, sl. sol. cold water.

Salts.—B''H$_2$Cl$_2$: long prisms.—B''H$_2$PtCl$_6$.

Di-amido-di-phenyl-sulphone di-carboxylic acid C$_{14}$H$_{12}$N$_2$SO$_6$ *i.e.* SO$_2$(C$_6$H$_3$(NH$_2$)CO$_2$H)$_2$, [above 350°]. Obtained from *p*-amido-benzoic acid and fuming H$_2$SO$_4$ at 180° (Michael a. Norton, *B.* 10, 580). Rose-red tufts of crystals (from water), sl. sol. alcohol.

Salt.—Ag$_2$A'': small white laminæ.

AMIDO-DI-PHENYL SULPHONIC ACIDS *v.* AMIDO-DIPHENYL.

AMIDO-PHENYL SULPHYDRATE *v.* AMIDO-PHENYL MERCAPTAN.

AMIDO-DIPHENYL DI-SULPHYDRATE $C_{12}H_{11}NS_2$ *i.e.* $C_{12}H_7(NH_2)(SH)_2$. [153°]. Prepared by reducing nitro-diphenyl di-sulphochloride with tin and HCl (Gabriel a. Dambergis, *B.* 13, 1411). Long needles.

***p*-AMIDO-DIPHENYL-*p*-THIO-GLYCOLLIC ACID** $C_{14}H_{13}NSO_2$ *i.e.* $H_2N.C_6H_4.C_6H_4.S.CH_2.CO_2H$. [Over 200°]. Formed by action of a chloro-acetate upon *p*-amido-diphenyl *p*-sulphydrate (Gabriel a. Dambergis, *B.* 13, 1410). Plates; sl. sol. water.

***o*-AMIDO-*s*-DI-PHENYL-THIO-UREA** $C_{13}H_{13}N_3S$ *i.e.* $C_6H_5NH.CS.NH.C_6H_4.NH_2$. From *o*-phenylene-diamine and phenyl thio-carbimide in benzene (Lellmann a. Würthner, *A.* 228, 212). Glittering prisms, v. sol. alcohol and glacial acetic acid, sl. sol. benzene, insol. ether. In a capillary tube it cakes together at 141°; at 185° aniline distils out of it; but at 250° it is still solid: *o*-phenylene-thio-urea being left: $PhHN.CS.NH.C_6H_4NH_2 =$

$$CS\genfrac{<}{>}{0pt}{}{NH}{NH}C_6H_4 + PhNH_2.$$

***m*-Amido-di-phenyl-thio-urea.** [148°]. From *m*-phenylene-diamine and phenyl thio-carbimide in benzene (L. a. W.). Amorphous yellow powder or colourless prisms (from alcohol). V. sol. glacial acetic acid, m. sol. alcohol, insol. ether and benzene. May be melted without decomposition. Decomposed by long boiling with alcohol, as follows: $2CS(NPhH)(NH.C_6H_4NH_2) = (PhHN.CS.NH)_2C_6H_4 + C_6H_4(NH_2)_2$. The *o* and *p* isomerides behave similarly.

***p*-Amido-*s*-di-phenyl-thio-urea.** From *p*-phenylene diamine and PhNCS dissolved in benzene (L. a. W.). Reddish prisms (from alcohol). Sol. glacial acetic acid, insol. ether or benzene. Begins to decompose at 163°, forming *p*-phenylene-thio-urea and aniline.

AMIDO-*p*-PHENYL-TOLUENE $C_{13}H_{13}N$ *i.e.* $C_{13}H_{11}.NH_2$. [93°–97°]. *Amido-tolyl-phenyl.* Obtained from *p*-phenyl-toluene, $C_6H_5.C_6H_4.CH_3$, by nitration and reduction (Carnelley, *C. J.* 29, 21).

Salt.—B'HCl. [c. 283°].

DI AMIDO-PHENYL-TOLYL-KETONE $C_{14}H_{14}N_2O$ *i.e.* $H_2N.C_6H_4.CO.C_6H_3(CH_3).NH_2$. [about 220°]. Colourless needles. Formed together with oxy-amido-phenyl-tolyl-ketone and di-oxy-benzophenone by heating commercial rosaniline with water at 270°.

Di-benzoyl derivative $C_{14}H_{10}O(NHBz)_2$. [226°], colourless needles (Liebermann, *B.* 16, 1927).

DI-AMIDO-PHENYL-TOLYL-METHANE *v.* DI-AMIDO-BENZYL-TOLUENE.

Di-amido-phenyl-di-tolyl-methane $C_{21}H_{22}N_2$ *i.e.* $C_6H_5CH(C_7H_6NH_2)_2$. [185°]. Formed by heating a mixture of *p*-toluidine, *p*-toluidine hydrochloride, and benzoic aldehyde for several hours at 120° (Ullmann, *B.* 18, 2094). It forms a compound with benzene, crystallising in glistening needles.

Tri-amido-di-phenyl-tolyl-methane $C_{20}H_{21}N_3$ *i.e.* $(H_2N.C_6H_4)_2CH.C_7H_6.NH_2$. *Leucaniline.* [100°]. Obtained by reducing rosaniline (*q. v.*) (Hofmann, *Pr.* 12, 9; Rosenstiehl a. Gerber, *A. Ch.* [6] 2, 341). Small crystals (from boiling water). Sl. sol. hot water, or ether, v. sol. alcohol. Converted into rosaniline by oxidation. Salts.—$B'''H_3Cl_3$ aq.—$B'''_2 3H_2PtCl_6$.—$B'''3HNO_3$.

Tri-acetyl derivative [168°]. Needles. Gives tetra-acetyl-rosaniline when oxidised with $K_2Cr_2O_7$ and acetic acid (Renouf, *B.* 16, 1303).

Tri-*p*-amido-phenyl-di-tolyl-methane $C_{21}H_{23}N_3$ *i.e.* $(H_2N.C_7H_6)_2CH.C_6H_4.NH_2$. Prepared by reduction of nitro-di-amido-phenyl-di-tolyl-methane with zinc dust and HCl (Fischer, *B.* 15, 680). Small colourless prisms or long needles. On oxidation it gives a rosaniline which dyes a bluer shade than ordinary rosaniline.

***o*-AMIDO-*s*-DI-PHENYL-UREA** $C_{13}H_{13}N_3O$ *i.e.* $NH_2.C_6H_4.NH.CO.NHC_6H_5$. From phenyl cyanate and *o*-phenylene diamine in benzene solution (Lellmann a. Würthner, *A.* 228, 220). Slender silky needles (from alcohol). V. sol. glacial acetic acid, m. sol. alcohol, v. sl. sol. benzene, insol. ether. In capillary tubes it cakes together and partially melts at 182°, splitting up into aniline and phenylene-urea, [305°].

***m*-Amido-*s*-di-phenyl-urea.** From *m*-phenylene diamine and PhNCO in benzene (L. a. W.). Grey needles (from dilute alcohol). V. sol. alcohol, and glacial acetic acid, sl. sol. ether and benzene. In capillary tubes it decomposes at 185° into aniline and *m*-phenylene-urea, [above 300°].

***p*-Amido-*s*-di-phenyl-urea.** From *p*-phenylene-diamine and PhNCO in benzene (L. a. W.). Slender white needles (from alcohol). Sol. glacial acetic acid, v. sl. sol. benzene, insol. ether. Decomposes about 210°–220° into aniline and *p*-phenylene-urea [above 320°].

Di-amido-di-phenyl-urea $C_{13}H_{14}N_4O$ *i.e.* $CO(NH.C_6H_4.NH_2)_2$. From tetra-nitro-di-phenyl-urea, $(C_6H_3(NO_2)_2.NH)_2CO$ by reducing with tin and HCl (Fleischer a. Nemes, *B.* 10, 1296). Laminæ (from alcohol); sl. sol. cold water.—$B'_2H_2PtCl_6$.

AMIDO-PHENYL-URETHANE *v.* AMIDO-PHENYL-CARBAMIC ETHER.

***o*-AMIDO-PHENYL-VALERIC ACID** [1:2] $C_6H_4(NH_2).CH_2.CH_2.CH_2.CH_2.CO_2H$. [62°]. White needles. Formed by boiling an alcoholic solution of *eso*-di-bromo-amido-phenyl-valeric acid with sodium-amalgam. It could not be converted into an inner-anhydride even by dehydrating-agents. *Acetyl derivative*: [151°] (Diehl a. Einhorn, *B.* 20, 385).

AMIDO-PHOSPHENYLIC ACID *v.* PHOSPHINES.

AMIDO-PHTHALIC ACID $C_8H_7NO_4$ *i.e.* $C_6H_3(NH_2)(CO_2H)_2$ [1:2:3].

Salt.—$H_2A''HSnCl_3$ 2aq: needles, got from nitro-phthalic acid by tin and HCl. The hydrochloride gives off CO_2 on evaporation, becoming *m*-amido-benzoic acid (Miller, *A.* 208, 245).

Ethyl ether Et_2A''. Oil; got by reducing ethyl *con*-nitro-phthalate.

Amido-phthalic acid $C_6H_3(NH_2)(CO_2H)_2$ [1:3:4]. Its hydrochloride splits up, like that of the preceding acid, into CO_2 and *m*-amido-benzoic acid (M.).

Ether Et_2A'' [95°] (M.). Got by reducing *u*-nitro-phthalic ether (M.; Koenigs, *B.* 10, 125). Monoclinic prisms (from alcohol). Ethereal solutions show faint blue fluorescence.

Acetyl derivative [122°]. Minute laminæ.

Amido-iso-phthalic acid $C_8H_7NO_4$ 2aq. [above 300°]. S. ·104 at 15°; ·92 at 99°.

Formed by reducing nitro-iso-phthalic acid, [249°] (Storrs a. Fittig, *A.* 158, 285; Beyer, *J. pr.* [2] 25, 491). Prisms (from alcohol) or plates (from water). Solutions give a deep reddish-brown colour with Fe_2Cl_6.

Salts: K_2A''; gives no pps. with salts of Ca or Ba, but pps. with salts of Zn, Cd, Cu, Ag, Pb, and Hg.—Na_2A''.—$MgA''4\frac{1}{2}aq$: S. 20 at 15°.—$CaA''3\frac{1}{2}aq$: S. 7·4 at 15°.—$SrA''aq$: S. 8·6 at 15°.—$BaA''1\frac{1}{2}aq$: S. 5·43 at 15°.—ZnA''. — CdA''. — $AgHA''$. — $H_2A''HCl\,aq$. — $(H_2A''HCl)_2PtCl_4\,3\frac{1}{2}aq$: crystals grouped in stars. —$H_2A''HBr$.—$H_2A''HNO_3\,1\frac{1}{2}aq$.

Methyl ether Me_2A'' [176°]; solidifies at 164°.

Ethyl ether Et_2A'' [118°]; solidifies at 113°. Prepared by treating a mixture of nitro-iso-phthalic ether (50 g.), alcohol (300 g.), and conc. HCl (500 g.), with zinc dust at 0°. Tufts of thin plates (from alcohol) or slender needles arranged in crosses (from water). V. sl. sol. water. Solutions fluoresce violet-red.

Amido-tere-phthalic acid $C_8H_7NO_4$ *i.e.* $C_6H_3(NH_2)(CO_2H)_2$ [2:1:4]. Obtained by reducing nitro-terephthalic acid with tin and HCl (Warren de la Rue a. Hugo Müller, *Pr.* 11, 112). Thin lemon-yellow prisms; v. sl. sol. cold water, alcohol, ether, or chloroform. Decomposed by heat without previous fusion. Its solution fluoresces blue.

Di-methyl ether Me_2A'' [126°]. **Salts:** $Me_2A''HCl$: white needles, saponified by water. —$(Me_2A''HCl)_2PtCl_4$ (Ahrens, *B.* 19, 1636).

Di-amido-terephthalic acid $C_8H_8N_2O_4$ *i.e.* $C_6H_2(NH_2)_2(CO_2H)_2$ [3:6:1:4].

Ether Et_2A'' [168°]. Formed by the action of bromine upon di-amido-di-hydro-terephthalic ether (di-imide of succino-succinic ether) dissolved in strong H_2SO_4. Glistening orange needles. Sparingly soluble in alcohol and ether with a yellow fluorescence. By diazotisation and treatment with Cu_2Cl_2 it is converted into di-chloro-terephthalic ether, which is reduced by sodium-amalgam to terephthalic ether. The sulphate forms very sparingly soluble colourless needles (Baeyer, *B.* 19, 430).

AMIDO - PHTHALIDE $C_8H_7NO_2$ *i.e.* $C_6H_3(NH_2){<}\begin{matrix}CO\\CH_2\end{matrix}{>}O\left[4:\begin{matrix}1\\2\end{matrix}\right]$. [178°]. Formed by reducing nitro-phthalide [141°] (Hoenig, *B.* 18, 3448). Short prisms; sol. chloroform, sl. sol. alcohol, ether, and benzene, v. sl. sol. cold water. **Salts:** $B'HCl$: needles.—$B'_2H_2PtCl_6$.

DI - AMIDO - ISO - PHTHALOPHENONE $C_{20}H_{16}N_2O_2$. Two isomeric compounds of this formula are obtained by reducing the two di-nitro-phthalophenones that are got by nitrating iso-phthalophenone $C_6H_4(CO.C_6H_5)_2$ [1:3] (Ador, *Bl.* [2] 33, 56).

AMIDO-PODOCARPIC ACID *v.* PODOCARPIC ACID.

DI-AMIDO-PROPANE *v.* TRIMETHYLENE-DIAMINE and PROPYLENE-DIAMINE.

(3:4:1)-AMIDO-PROPENYL-BENZOIC ACID $C_{10}H_{11}NO_2$ *i.e.* $C_6H_3(NH_2)(C_3H_5)CO_2H$ [3:4:1] [94°]. *Formation*:—1. By reduction of nitro-propenyl-benzoic acid with $FeSO_4$ and NH_3.—2. By boiling amido-oxypropyl-benzoic acid with HCl (Widman, *B.* 16, 2572). Long white needles. Easily soluble in alcohol, ether, and benzene, sparingly in water and ligroine. Tolerably marked basic properties.

Salts: $A'H,HCl$; long colourless easily soluble prisms. — $(A'H,HCl)_2PtCl_4$; easily soluble yellow needles.—$A'H, AcOH$: colourless prisms, [c. 160°].

Acetyl derivative $C_6H_3(NHAc)(C_3H_5)CO_2H$—[212°], long white needles, sl. sol. hot water. By the action of nitrous acid it is converted into methyl-cinnoline carboxylic acid $CO_2H.C_6H_3{<}\begin{matrix}CMe:CH\\N\ \ :\ \ N\end{matrix}{>}$, di-azo-propenyl-benzoic acid, $CO_2H.C_6H_3{<}\begin{matrix}CMe:CH_2\\N:N.OH\end{matrix}$, probably being the intermediate product (Widman, *B.* 17, 722).

Amido-propenyl-benzoic acid $C_6H_3(NH_2)(C_3H_5)CO_2H$ [2:4:1]. [165°]. Formed by heating amido-oxypropyl-benzoic acid with dilute HCl (Widman, *B.* 19, 272). Yellow plates.

Acetyl derivative: [122°]; white prisms.

a-AMIDO-PROPIONAMIDE $C_3H_8N_2O$ *i.e.* $CH_3.CH(NH_2).CO.NH_2$. [above 250°]. Occurs in urine (Baumstark, *A.* 173, 342). Small columns, sl. sol. cold water, m. sol. hot water, insol. ether insol. alcohol (difference from urea). Converted by nitrous acid into sarco-lactic acid, and by baryta-water at 150° into CO_2, NH_3, and ethylamine.

a-AMIDO-PROPIONIC ACID *v.* ALANINE.

β-Amido-propionic acid $C_3H_7NO_2$ *i.e.* $CH_2(NH_2).CH_2.CO_2H$. [180°]. Mol. w. 89.

Formation.—1. Together with β-imido-propionic acid, by the action of NH_3 upon β-iodo-propionic acid (Heintz, *A.* 156, 36; Mulder, *B.* 9, 1903).—2. From cyano-acetic acid by reduction with Zn and H_2SO_4 (Engel, *B.* 8, 1597).

Properties.—Prisms; v. e. sol. water, sl. sol. alcohol. Sweet taste. Split up by distillation into NH_3 and acrylic acid.

Salt.—$CuA'_2\,5aq$: dark-blue prisms.

(a)-AMIDO-PROPIONITRILE $C_3H_6N_2$ *i.e.* $CH_3.CH(NH_2).CN$. A mixture of aldehyde-ammonia and prussic acid (30 p.c. solution) is acidified with H_2SO_4Aq (1:3) (Erlenmeyer a. Passavant, *A.* 200, 121). Liquid; quickly changes to imido-propionitrile, giving off NH_3. —$B'HCl$.—$B'_2H_2PtCl_6$.

AMIDO-PROPYL-ALCOHOL *v.* OXY-PROPYL-AMINE.

AMIDO-ISOPROPYL-BENZOIC ACID AMIDO-CUMINIC ACID.

AMIDO-*n*-PROPYL-CINNAMIC ACID $C_{12}H_{15}NO_2$ *i.e.* $C_6H_3(C_3H_7)(NH_2).C_2H_2.CO_2H$ [4:2:1] [155°]. Formed by reduction of nitro-*n*-propyl-cinnamic acid with $FeSO_4$ and NH_3 (Widman, *B.* 19, 277). Glistening yellow needles. Easily soluble in hot alcohol. By heating with dilute HCl for a long time it is converted into *n*-propyl-carbo-styril [162°].

a-AMIDO-*p*-PROPYL-PHENYL-ACETIC ACID $C_{11}H_{15}NO_2$ *i.e.* $C_3H_7.C_6H_4.CH(NH_2).CO_2H$. [197°]. Prepared by saponifying the product of the action of HCN upon cumin-hydramide (Plöchl, *B.* 14, 1316). Sl. sol. cold water, insol. alcohol and ether.

AMIDO-PYRENE *v.* PYRENE.

AMIDO-PYROCATECHIN ×$C_6H_7NO_2$ *i.e.* ×$C_6H_3(NH_2)(OH)_2$. By reducing the nitro-compound by Sn and HCl.

Salt: $B'HCl$: dark needles. Sodic car-

bonate liberates the free base which, however, is rapidly oxidised by air forming a violet solution (Benedikt, *J. pr.* **[2] 18, 457;** *B.* **11, 363).**

Methylene derivative $C_7H_7NO_2$ *i.e.*

$H_2N.C_6H_3\langle{}^{O}_{O}\rangle CH_2$. Obtained by reducing methylene-nitro-pyrocatechin or nitro-piperonylic acid (Hesse, *A.* 199, 341). Brownish oil. Salt: B′HCl.

AMIDO-PYROGALLOL $C_6H_7NO_3$ *i.e.* $C_6H_2(NH_2)(OH)_3$. *Amido-pyrogallic acid.* From the nitro-compound. Its alkaline solution turns blue in air.

Salt.—B′HCl: needles (Barth, *M.* 1, 884).

AMIDO-PYRO-MECONIC ACID $C_5H_5NO_3$ *i.e.* $C_5H_3(NH_2)O_3$. From nitro-pyro-meconic acid, tin and HCl (Ost, *J. pr.* [2] 19, 194). Needles (from water). Fe_2Cl_6 gives a blue colour, changed to red by excess.—B′HCl aq.

Di-amido-pyro-mellitic ether $C_6(NH_2)_2(CO_2Et)_4$ [134°]. From the nitro compound (Nef, *A.* 237, 24). *Diacetyl derivative* [149°].

(*a*)-**AMIDO-PYRRYL METHYL KETONE** $C_6H_8N_2O$ *i.e.* $C_4H_3(NH_2)N.CO.CH_3$. Formed by reduction of (*a*)-nitro-pyrryl methyl ketone with tin and HCl (Ciamician a. Silber, *B.* 18, 1460).—$B'_2H_2PtCl_6$: long yellow needles.

(*B.* 4)-**AMIDO-QUINOLINE** $C_9NH_6.NH_2$. [67°].

Preparation.—1. By reducing nitro-quinoline, [89°] (Koenigs, *B.* 12, 451).—2. By heating oxy-quinoline with zinc-chloride-ammonia (Bedall a. Fischer, *B.* 14, 2573). Plates. Dissolves in acids. CrO_3 gives a blood-red colour.

(*B.* 2)-**Amido-quinoline** $C_9H_8N_2$ [114°]. Prepared by reduction of nitro-quinoline from *p*-nitraniline (La Coste, *B.* 16, 670). Colourless plates or flat needles (containing 2aq). Sublimable. V. sol. alcohol and ether, less in water and ligroïn. Salts: B″HCl: large colourless prisms.—$B''_2H_2Cl_2PtCl_4$ 2aq.: crystalline pp.

Picrate $B''(C_6H_2(NO_2)_3OH)_2$: needles.

(*B.* 3)-**Amido-quinoline**

$C_6H_3(NH_2)\langle{}^{CH:CH}_{N=CH}$. [110°]. Prepared by heating (*B.* 3)-oxy-quinoline with ammoniacal $ZnCl_2$ (Riemerschmied, *B.* 16, 725). Yellow plates. Sublimable. Sol. alcohol, ether, and hot water; sl. sol. cold water. The *picrate* forms long red needles, v. sl. sol. ether.

(*a*)-**Di-amido-quinoline** $C_9H_9N_3$ *i.e.* $C_9H_5(NH_2)_2N$. [156° uncorr.]. Formed by reduction of (*a*)-di-nitro-quinoline [183°] with $SnCl_2$ (Claus a. Kramer, *B.* 18, 1247). Thick yellowish needles.—$B''H_2Cl_2PtCl_4$: red needles.

(*β*)-**Di-amido-quinoline.** [163° uncorr.]. Formed by reduction of (*β*)-di-nitro-quinoline [134°] with $SnCl_2$ (C. a. K.). Small yellow needles or plates. Is not sublimable or volatile with steam. V. sol. water and alcohol, sl. sol. ether, benzene, and ligroïn.—$B_2H_2Cl_2PtCl_4$: yellow crystalline powder.

DI-AMIDO-QUINONE $C_6H_2(NH_2)_2O_2$ [6:2:4:1].

Diacetyl derivative $C_6H_2(NHAc)_2O_2$: [265°–270°]. Formed by oxidation of tetra-acetyl-di-amido-hydroquinone $C_6H_2(NHAc)_2(OAc)_2$ or tri-acetyl-tri-amido-phenol $C_6H_2(NHAc)_3OH$ (from picric acid). By heating with $SnCl_2$ dissolved in conc. HCl it yields di-amido-hydroquinone (Nietzki a. Preusser, *B.* 19, 2247; 20, 797).

DI-AMIDO-QUINONE-IMIDE *v.* AMIDO-DI-IMIDO-PHENOL.

(*B.* 2)-**AMIDO-QUINOXALINE** $C_8H_7N_3$ *i.e.*

$C_6H_3(NH_2)\langle{}^{N:CH}_{N:CH}$ [159°]. Formed by condensation of glyoxal with (1:2:4)-tri-amido-benzene (Hinsberg, *B.* 19, 1254). Yellow needles or large crystals. Sublimable. V. sol. water, alcohol, and chloroform, m. sol. ether and benzene. The ethereal and chloroform solutions have a yellowish-green fluorescence. The aqueous solution gives yellow pps. with $AgNO_3$ and $HgCl_2$. Its solution in HCl is deep violet.

Salts.—B′HCl: brown plates with green reflection.—$B'_2H_2SO_4$.—$B'_2H_2Cl_2PtCl_4$.

AMIDO-RESORCIN $C_6H_7NO_2$ *i.e.* [1:2:4] $C_6H_3(NH_2)(OH)_2$. Formed by reducing nitro-resorcin with tin and HCl (Weselsky, *A.* 164, 6).—B′HCl 2aq: gives brown colour with Fe_2Cl_6. The free base is unstable.

Ethers: $C_6H_3(NH_2)(OEt)_2$: [32°]; (251°). From benzene-azo-di-ethyl-resorcin (Will a. Pukall, *B.* 20, 1124).—$C_6H_3(NH_2)(OH)(OEt)$. [148°].

Amido-resorcin. *Ethyl ether* $C_6H_3(NH_2)(OEt)_2$ [1:2:6]. [124°]. From benzene-*o*-azo-di-ethyl-resorcin (Pukall, *B.* 20, 1148).

Di-amido-resorcin $C_6H_8N_2O_2$ *i.e.* $C_6H_2(NH_2)_2(OH)_2$. [1:3:4:6]. The hydrochloride is obtained by reducing dinitroso-resorcin (Fitz, *B.* 8, 633) or benzene-disazo-resorcin (Liebermann a. Kostanecki, *B.* 17, 881). It gives a blue colour with Fe_2Cl_6. The free base is unstable. If the hydrochloride is suspended in chloroform, a little aqueous NaOH added, and then a large quantity of water, a beautiful blue colour is produced.—$B''H_2SO_4$ 1½aq.

Di-amido-resorcin. Formed by reduction of di-nitro-resorcin with tin and HCl (Typke, *B.* 16, 555). The hydrochloride ($B''H_2Cl_2$) forms easily soluble flat needles. Fe_2Cl_6 produces a ppn. of steel-blue prisms of di-imido-resorcin.

AMIDO-SALICYLIC *v.* OXY-AMIDO-BENZOIC.

DI-AMIDO-STILBENE *v.* DI-AMIDO-DI-PHENYL-ETHYLENE.

AMIDO-STRYCHNINE $C_{21}H_{23}N_3O_2$ *i.e.* $C_{21}H_{21}(NH_2)N_2O_2$. [275°]. (c. 280°) at 5 mm. From nitro-strychnine and $SnCl_2$ (Loebisch a. Schoop, *M.* 6, 848). Cubes (from alcohol). Insol. water, sl. sol. benzoline, m. sol. alcohol, v. e. sol. ether and chloroform. Its salts are very much more soluble than those of strychnine; they turn reddish-violet in moist air. They give the general reactions for alkaloids. Give no colour with conc. H_2SO_4 and $K_2Cr_2O_7$. A dilute acid solution is turned blue by aqueous $K_2Cr_2O_7$ or by Fe_2Cl_6. Salts.—B″2HCl: prisms.—$B''H_2PtCl_6$.

Acetyl derivative $C_{21}H_{21}(NAcH)N_2O_2$ aq [205°] (L. a. S. *M.* 7, 77).

Di-amido-strychnine $C_{21}H_{20}(NH_2)_2N_2O_2$. [263°]. From di-nitro-strychnine, tin, and HCl (Hanriot, *C. R.* 96, 586; *Bl.* [2] 41, 236). Prisms (from chloroform); v. sl. sol. water and ether, m. sol. alcohol, v. sol. chloroform. Gives no colour with conc. H_2SO_4 and $K_2Cr_2O_7$. A dilute acid solution is turned violet-blue by oxidising agents such as $K_2Cr_2O_7$Aq or NaOCl.

p-**AMIDO-STYRENE** C_8H_9N *i.e.* $C_6H_4(NH_2).CH:CH_2$. [76°-81°]. A body of this composition is formed by reducing *p*-nitro-

cinnamic acid with tin and HCl (Bender, *B.* 14, 2359), and by heating *p*-amido-cinnamic acid (Bernthsen a. Bender, *B.* 15, 1982).—$B'_2H_2PtCl_6$.

o-**AMIDO-STYRYL-ACRYLIC ACID** $C_{11}H_{11}NO_2$ *i.e.* $C_6H_4(NH_2).CH:CH.CH:CH.CO_2H$. *o-Amido-cinnamenyl-acrylic acid.* [177°]. Formed by reduction of *o*-nitro-styryl-acrylic acid with ferrous sulphate and ammonia. Yellow needles. V. sol. chloroform, ether, alcohol, and acetic acid, sl. sol. CS_2 and hot water, v. sl. sol. cold water. Its ethereal solution has a green fluorescence. It forms salts with acids and with bases. The hydrochloride is easily soluble, the sulphate sparingly soluble. The salts with bases are deep yellow.

Acetyl derivative $C_6H_4(NHAc).C_4H_4.CO_2H$: [253°]. Small white tables, sol. hot alcohol, sl. sol. cold alcohol and ether, insol. water (Diehl a. Einhorn, *B.* 18, 2332).

o-**AMIDO-STYRYL-PROPIONIC ACID** $C_6H_4(NH_2).CH:CH.CH_2.CH_2.CO_2H$. *o-Amido-cinnamyl-acetic acid.* [59° hydrated]. Crystals ($+H_2O$). Easily soluble in ordinary solvents. Formed by reduction of *o*-amido-styryl-acrylic acid with sodium-amalgam (Diehl a. Einhorn, *B.* 20, 378).

AMIDO-SUCCINAMIC ACID *v.* Asparagine.

AMIDO-SUCCINIC ACID *v.* Aspartic acid.

Di-amido-succinic acid $C_4H_8N_2O_4$ *i.e.* $CO_2H.CH(NH_2).CH(NH_2).CO_2H$. [125°].

Formation.—1. From di-bromo-succinic acid and NH_3 (Lehrfeld, *B.* 14, 1817).—2. By reducing the di-phenylhydrazide of di-oxy-tartaric acid, $CO_2H.C(N_2HPh).C(N_2HPh).CO_2H$, in alkaline solution with sodium amalgam. The yield is 35 p.c. of the theoretical (Tafel, *B.* 20, 247).

Properties.—Prisms; v. sl. sol. water, alcohol, ether, acetone, acetic acid, chloroform, aniline, phenol, and CS_2. Sol. aqueous acids and alkalis.

Di-amido-succinic acid $C_4H_8N_2O_4$. [151° uncorr.]. White needles or prisms. Sol. water, alcohol, and ether. The acid is isomeric with the preceding. The ether is formed by the action of NH_3 on di-chloro-succinic ether.

Diethyl-ether $A''Et_2$. [122° uncorr.] Colourless needles or trimetric prisms. Sol. alcohol and ether, v. sl. sol. water.

Salts.—$A''Ag_2$ and $A''Pb$: insol. pps.—$A''Cu$: green pp.

Di-amide $C_2H_6N_2(CO.NH_2)_2$. [160° uncorr.]. Long slender needles. Insol. water and ether (Claus a. Helpenstein, *B.* 14, 624; 15, 1850).

AMIDO-SUCCINURIC ACID *v.* Uramido-succinic acid.

AMIDO-SULPHOBENZIDE *v.* Amido-diphenyl sulphone.

AMIDO-SULPHO-BENZOIC ACID $C_7H_7NSO_5$ *i.e.* $C_6H_3(NH_2)(SO_3H)(CO_2H)$ [1:3:5]. From nitro-*m*-sulpho-benzoic acid and aqueous ammonium sulphide (Limpricht a. Uslar, *A.* 106, 29). Needles, v. sol. hot water, m. sol. alcohol, v. sl. sol. ether. Blackened by heat. Combines with bases but not with acids.

(α)-amido-sulpho-benzoic acid $C_7H_7NSO_5aq$ *i.e.* $C_6H_3(NH_2)(SO_3H)(CO_2H)$ [1:*x*:5]. Obtained, together with the following acid, by sulphonation of *m*-amido-benzoic acid (Griess, *J. pr.* [2] 5, 244). Four-sided laminæ, m. sol. hot water.—Salt:—$BaA''2aq$: v. sl. sol. water.

(β)-amido-sulpho-benzoic acid $C_7H_7NSO_5$ *i.e.* $C_6H_3(NH_2)(SO_3H)(CO_2H)$ [1:*x*:5]. Six-sided laminæ; v. sl. sol. hot water.—Salt: $BaA''3aq$: m. sol. water.

Amido-sulpho-benzoic acid $C_6H_3(NH_2)(SO_3H)(CO_2H)$ [1:3:6]. Rhombic plates, sol. hot water. Dilute solutions show blue fluorescence (Hart, *Am.* 1, 363).

Amido-sulpho-benzoic acid $C_6H_3(NH_2)(SO_3H)(CO_2H)$ [1:2:4].

Imide $C_6H_3(NH_2)<\substack{SO_2\\CO}>NH$. [285°]. From the amide of *p*-nitro-toluene sulphonic acid by oxidation and reduction (Noyes, *Am.* 8, 167). Colourless crystals, v. sl. sol. water. Its solution shows dark blue fluorescence.

AMIDO-SULPHO-BENZOLIC ACID. An old name for amido-benzene sulphonic acid *v.* Amido-benzene.

AMIDO-SULPHO-PHENOLIC ACID. An old name for amido-phenol sulphonic acid *v.* Amido-phenol.

α-**AMIDO-*p*-SULPHO-PHENYL-PROPIONIC ACID** $C_9H_{11}NSO_5$ *i.e.*
$SO_3H.C_6H_4.CH_2.CH(NH_2).CO_2H$.
From α-amido-phenyl propionic acid (20 g.), conc. H_2SO_4 (30 g.) and Nordhausen acid (25 g.) (Erlenmeyer a. Lipp, *A.* 219, 209). Groups of short prisms (from water). M. sol. water, v. sl. sol. alcohol, insol. ether. Does not combine with HCl. Fused with KOH gives *p*-oxy-benzoic acid.—Salts: $BaA'_2 4aq$: flat prisms.

AMIDO-TEREPHTHALIC ACID *v.* Amido-phthalic acid.

m-**AMIDO-THIO-BENZAMIDE** $C_7H_8N_2S$ *i.e.* $C_6H_4(NH_2).CS.NH_2$. Obtained by boiling *m*-nitro-benzonitrile with aqueous ammonium sulphide (Hofmann, *Pr.* 10, 598; *B.* 1, 197). Needles (from water). Weak base. Decomposed by heat into H_2S and amido-benzonitrile. Alcoholic solution of iodine converts it into $C_{14}H_{12}N_4S$, crystallising from water in slender needles [129°]. Forms a platino-chloride $C_{14}H_{12}N_4SH_2PtCl_6$ (Wanstrat, *B.* 6, 332).

***p*-Amido-thio-benzamide** [170°]. From *p*-nitro-benzonitrile and conc. H_2SO_4 (Engler, *A.* 149, 299). Crystals; m. sol. alcohol.

AMIDO-THIO-CRESOL *v.* Amido-tolyl mercaptan.

AMIDO-THIOPHENE $C_4SH_3(NH_2)$. Prepared by reducing nitro-thiophene with tin and alcoholic HCl (Stadler, *B.* 18, 1490, 2316). Yellow oil. Very unstable; being changed in 12 hours into a brittle resin. The hydrochloride reacts with diazo salts forming stable azo compounds. Salts.—$B'HCl$.—$B'_2H_2SnCl_4$.

α-**AMIDO-THIENYL-ACETIC ACID** $C_6H_7SNO_2$ *i.e.* $C_4SH_3.CH(NH_2).CO_2H$. Formed by reducing the oxim of thienyl-glyoxylic acid $C_4SH_3.C(NOH).CO_2H$ with tin and HCl (Bradley, *B.* 19, 2115). Plates or grains; decomposes at 235°–240°. Salts.—The acid gives pps. with salts of Cu, Hg, Bi, and Zn, but no pps. with salts of Fe, Mg, Mn, Ur, Ni, Ba, Ca, Sn, or Pb.—CuA'_2aq.—$HA'HCl$.

AMIDO-THIOPHENOL *v.* Amido-phenyl mercaptan.

AMIDO-THYMOL $C_{10}H_{15}NO$ *i.e.* $C_6H_2Pr(NH_2)(CH_3)(OH)$ [1:3?:4:6]. Nitroso-thymol, prepared from sodium-thymol, KNO_2 and H_2SO_4 (Schiff, *B.* 8, 1500), is reduced by Sn and HCl to the well-crystallised tin salt of *p*-amido-thymol. This is dissolved in water and decomposed by H_2S (Andresen, *J. pr.* 131, 169).—**Salt**: $B'HCl$: decomposes at 210°–215°.

Reactions.—1. *Bleaching powder* solution converts it into thymo-quinone-chloro-imide (*q.v.*).—2. A solution of *bromine* in NaOH oxidises it to thymo-quinone.—3. *Bromine water* has the same effect.

Amido-thymol sulphonic acid $C_{10}H_{14}(SO_3H)NO$ is among the products of the action of conc. $NaHSO_3Aq$ upon thymoquinone-chloro-imide (A.). Needles or prisms.

Di-amido-thymoquinone $C_{10}H_{14}N_2O_2$ *i.e.* $C_6PrMe(NH_2)_2O_2$ or *Oxy-amido-thymo-quinon-imide*  $C_6PrMe(NH_2)(OH)\langle\begin{matrix}O\\ |\\ NH\end{matrix}$. Formed by heating phenylamido-oxy-thymoquinone with alcoholic NH_3 at 100° (Anschütz a. Leather, *C.J.* 49, 725). Dark blue crystals, insol. water, ether, benzene, chloroform, and CS_2; v. sl. sol. alcohol; sol. glacial HOAc (crystallising with ½HOAc); v. sol. HClAq, forming a red solution.

AMIDO-TOLUENE *v.* TOLUIDINE and BENZYLAMINE.

Di-amido-toluene *v.* TOLYLENE-DIAMINE and AMIDO-BENZYLAMINE.

TRI-AMIDO-TOLUENE $C_7H_{11}N_3$ *i.e.* $C_6H_2Me(NH_2)_3$ [1:3:4:5].

p-Acetyl derivative $C_6H_2Me(NHAc)(NH_2)_2$ [1:4:3:5] [c. 264°]; pearly rods (containing aq); sol. acetic acid and hot alcohol, insol. water, ether, and benzene. Formed by reduction of acetyl-di-nitro-*p*-toluidine (1 pt.) with tin (3 pts.) and conc. HCl (8 pts.). The hydrochloride ($B'HCl$ ½aq) forms white concentric easily soluble needles (Niementowski, *B.* 19, 716).

Benzoyl derivative $C_6H_2Me(NHBz)(NH_2)_2$ [1:4:3:5] [c. 185°]. Formed by reducing benzoyl-di-nitro-*p*-toluidine (Hübner, *A.* 208, 318). Insol. water, sol. alcohol and ether. Salts.—$B''2HCl$.—$B''H_2SO_4$.

Tri-amido-toluene $C_6H_2(CH_3)(NH_2)_3$ [1:2:4:?]. Very oxidisable crystalline solid. Tri-acid base. Prepared by reduction of nitro-tolylene-*m*-diamine. $B'''(HCl)_3$ and $B'''_2(H_2SO_4)_3$ are white crystalline solids (Ruhemann, *B.* 14, 2657).

AMIDO-TOLUENE SULPHINIC ACIDS $C_7H_9NSO_2$.

***o*-Amido-toluene sulphinic acid** $C_6H_3Me(NH_2)SO_2H$ [1:2:4]. *o-Toluidine sulphinic acid.* S. ·148. From *o*-amido-toluene thiosulphonic acid and sodium amalgam (Paysan, *A.* 221, 361). Rectangular tables, sl. sol. water or alcohol, insol. ether or benzene. At 160° it decomposes without melting.

Reactions.—1. With yellow *ammonic sulphide* forms amido-toluene thiosulphonic acid.—2. $KMnO_4$ forms amido-toluene sulphonic acid.—3. Boiling HCl forms the isomeric toluene sulphamine.—4. *Nitrous acid* forms a diazo compound which when warmed with alcohol forms the ethyl derivative of cresol sulphonic acid.

Salts.—KA'.—BaA'_2 2aq.—AgA'.

Toluene sulphamine $C_7H_9NSO_2$. [175°]. Got by heating *o*-amido-toluene sulphinic acid with HCl and ppn. by NH_3. Needles in stars (from alcohol).—$B'HCl$: groups of slender needles.

***p*-Amido-toluene sulphinic acid** $C_7H_9NSO_2$ *i.e.* $C_6H_3(NH_2)Me.SO_2H$ [1:4:5]. From $C_6H_3(NH_2)Me(SO_2SH)$ by boiling with HCl but since much then changes to toluene sulphamine it is better to reduce it with sodium amalgam (Heffter, *A.* 221, 347). Hard prisms. Does not melt below 240°. Insol. alcohol, sl. sol. cold water, v. sol. hot water.

Reactions.—1. Warmed with a solution of *sulphur in ammonic sulphide* it changes to the thiosulphonic acid, $C_6H_3(NH_2)Me.(SO_2SH)$.—2. *Bromine* converts it into amido-toluene sulphonic acid.—3. Not reduced by Sn and HCl.

Salts.—KA'.—BaA'_2xaq.

Toluene sulphamine (isomeric with the above). [132°]. Got by heating *p*-amido-toluene sulphinic acid with conc. HCl. It is a base. Microscopic prisms (got by adding NH_3 to its solution in HCl). V. sol. alcohol and ether, but separates from them in a resinous form; sl. sol. water. Dissolved by treatment with water and sodium amalgam (not NaOH alone) forming sodic amido-toluene sulphinate.

Salts.—$B'HCl$: sl. sol. HCl, v. sol. water or alcohol.—$B'_2H_2SO_4$.—$B'HBr$: changes readily into amido-toluene sulphonic acid.—$B'HNO_3$: warmed with HNO_3 forms amido-toluene sulphonic acid.

Di-amido-toluene sulphinic acid $C_7H_{10}N_2SO_2$ *i.e.* $C_6H_2Me(NH_2)_2SO_2H$. *Tolylene-di-amine sulphinic acid.* S. ·047 at 20°. From $C_6H_2Me(NH_2)_2SO_2SH$ by boiling with HCl (Perl, *B.* 18, 70). Silky needles (containing aq). V. sl. sol. water, insol. alcohol, ether, and glacial HOAc.—PbA'_2 2aq: minute needles.

AMIDO-TOLUENE SULPHONIC ACIDS $C_7H_9NSO_3$ (Limpricht, *B.* 18, 2172).

***o*-Amido-toluene sulphonic acid** $C_6H_3Me(NH_2)SO_3H$aq [1:2:5]. *o-Toluidine sulphonic acid.* S. 2·76 at 12° (H. Hasse).

Preparation.—1. By heating the acid sulphate of *o*-toluidine at 220°–230°, or in a metal dish till solid (Nevile a. Winther, *C. J.* 37, 626; *B.* 13, 1941; Gerver, *A.* 169, 374; Pagel, *A.* 176, 292).—2. By reducing the corresponding nitro acid (Foth, *A.* 230, 306).

Salts.—KA'aq: tables and prisms.—NaA'4aq: tables.—$BaA'_2$7aq: tables and prisms.—AgA': prisms.

Reactions.—1. *Bromine water* forms first $CH_3.C_6H_2Br(NH_2)SO_3H$ [1:3:2:5] then di-bromo-toluidine $C_6H_2(CH_3)(NH_2)Br_2$[1:2:3:5][46°] is ppd. 2. Fused with *alkalis* or heated with water or aqueous HCl to 190° it forms *o*-toluidine.—3. *Nitrous acid* and alcohol give *m*-toluene sulphonic acid.—4. With *o-toluidine* at 235° it forms a red dye.

***o*-Amido-toluene sulphonic acid** $C_6H_3Me(NH_2)(SO_3H)$ [1:2:3]. Obtained by reducing the corresponding nitro acid (Pechmann, *A.* 173, 215). Minute needles; sl. sol. cold water. Gives *o*-toluidine when fused with KOH.

***o*-Amido-toluene sulphonic acid** $C_6H_3Me(NH_2)(SO_3H)$aq [1:2:4]. From the nitro acid (Bek, *Z.* 1869, 211; Beilstein a. Kuhlberg, *A.* 155, 21; Weckwarth, *A.* 172, 193; Hayduck, *A.* 172, 204; 174, 343; Herzfield, *B.* 17, 904). Long needles or four-sided prisms. S. ·974 at 11°; insol. alcohol. The aqueous solution is turned violet by Fe_2Cl_6. Potash-fusion gives *o*-amido-benzoic acid. Bromine gives di-bromo-toluidine sulphonic acid. Salts.—NaA'4aq.—KA'aq.—$BaA'_2$2½aq.—PbA'_2.

Amide.—$C_6H_3Me(NH_2)SO_2NH_2$. [175°]. S. ·22 at 23°. From $C_6H_3Me(NO_2)SO_2NH_2$, [128°], NH_3, and H_2S (Paysan, *A.* 221, 210). Four-sided columns.

Salt.—$C_6H_3Me(NH_3Cl).SO_2NH_2$. [240°].

***m*-Amido-toluene sulphonic acid**

$C_6H_3Me(NH_2)SO_3H$ [1:3:2]. *m-Toluidine sulphonic acid* [275°]. By sulphonation of *m*-toluidine (Lorenz, *A.* 172, 185). Tables or plates; sl. sol. water. Bromine-water produces tri-bromo-toluidine.

Salts.—$BaA'_2 9aq$.—$PbA'_2 3\frac{1}{2}aq$.

***m*-Amido-toluene sulphonic acid**

$C_6H_3Me(NH_2)SO_3Haq$. S. (dry) ·14 at 19°. From bromo-toluene sulphonic acid $C_6H_3MeBrSO_3H$ [1:2:4] by nitration and reduction (Hayduck, *A.* 174, 350). Minute needles.

***p*-Amido-toluene *exo*-sulphonic acid**

$C_6H_4(NH_2).CH_2.SO_3H$ [1:4]. *p-Amido-benzyl-sulphonic acid.* S. ·097 at 10°. Formed by reducing the nitro acid by NH_3 and H_2S (Mohr, *A.* 221, 219). Prisms, insol. alcohol, sl. sol. cold water.

Salts.—$KA'2\frac{1}{2}aq$.—$BaA'_2 8aq$.

The diazo derivative, $C_6H_4<\begin{matrix}N_2\\CH_2.SO_3\end{matrix}>$ is converted into $C_6H_4(OEt).CH_2.SO_3H$ by heating with alcohol under 1100 mm. pressure.

***p*-Amido-toluene sulphonic acid**

$C_6H_3Me(NH_2)SO_3Haq$ [1:4:2]. *p-Toluidine sulphonic acid.* S. ·45 at 20°. A product of sulphonation of *p*-toluidine (Sell, *A.* 126, 155; Malycheff, *Z.* 1869, 212); formed also by reducing *p*-nitro-toluene sulphonic acid (Beilstein a. Kuhlberg, *A.* 172, 230). Rhombohedra (containing aq). Reduces warm ammoniacal $AgNO_3$. Its aqueous solution is turned red by Fe_2Cl_6 (Herzfeld, *B.* 17, 904).

Salts.—KA'.—BaA'_2aq.—PbA'_2.

Amide.—$C_6H_3Me(NH_2)SO_2NH_2$. [164°]. From $C_6H_3Me(NO_2).SO_2NH_2$ [186°] by reducing with NH_3, and H_2S (Heffter, *A.* 221, 209). **Salt:** $C_6H_3Me(NH_3Cl)SO_2NH_2$; converted by conc. HCl and nitrous acid into $C_6H_3MeCl.SO_2NH_2$ [138°].

***p*-Amido-toluene sulphonic acid**

$C_6H_3Me(NH_2)SO_3H$ [1:4:3]. S. 10.

Preparation.—1. By sulphonating *p*-toluidine at 180°; the preceding acid is also formed, especially if the operation is protracted (Pechmann, *A.* 173, 195).—2. By heating *p*-toluidine acid sulphate at 220°-240° (Nevile a. Winther, *C. J.* 37, 632).

Properties.—Yellowish crystals. Less soluble in cold water than the *o*-compound.

Reactions.—1. *Bromine* forms much di-bromo-toluidine, $C_6H_2(CH_3)(NH_2)BrBr$ [1:4:3:5], [73°] and also a bromo-toluidine sulphonic acid. 2. *Water* at 180° forms *p*-toluidine and H_2SO_4.—3. *Potash-fusion* gives *p*-oxy-benzoic acid.—4. *Nitrous ether* gives *m*-toluene sulphonic acid.

Salts.—$BaA'_2 3aq$.—$PbA'_2 2aq$.—AgA'.—The K salt is insol. in cold KOHAq (difference from preceding acid; Schneider, *Am.* 8, 274).

Amido-toluene-*o*-sulphonic acid

$C_6H_3Me(NH_2)(SO_3H)$ [1:*x*:2]. S. ·34 at 22°. From the (1, 4, 2) acid by nitration, removal of NH_2, and reduction (Pagel, *A.* 176, 305).—$BaA'_2 2\frac{1}{2}aq$.—PbA'_2aq.

Amido-toluene sulphonic acid. Obtained by reducing the product of successive sulphonation and nitration of toluene (Hayduck, *A.* 177, 57).—Minute crystals (containing aq).—BaA'_2.

***o*-Amido-toluene di-sulphonic acid**

$C_7H_9NS_2O_6$ *i.e.* $C_6H_2Me(NH_2)(SO_3H)_2$ [1:2:3:5]. *o-Toluidine di-sulphonic acid.* Formed from $C_6H_3Me(NH_2)SO_3H$ [1:2:5] and fuming H_2SO_4 by heating an hour at 160° (Nevile a. Winther, *C. J.* 41, 421). Needles, grouped in stars; sol. water and alcohol.

Salts (H. Hasse, *A.* 230, 287).—$BaA''3aq$.—$BaH_2A''_2 3\frac{1}{2}aq$. — $K_2A''2aq$. — $Na_2A''6aq$. — $CaA''5aq$.—$PbA''2aq$.—$PbH_2A''_2 6\frac{1}{2}aq$.

Reactions.—1. By conversion into the *diazo compound* and subsequently boiling with HNO_3 it is converted into di-nitro-*o*-cresol $C_6H_2Me(OH)(NO_2)_2$ [1:2:3:5].—2. At about 240° it splits up into SO_3 and $C_6H_3Me(NH_2)(SO_3H)$ [1:2:5].—3. By $Cl.SO_3H$ at 230° it is changed into an isomeric acid with a salt $K_2A''6aq$.

***o*-Amido-toluene disulphonic acid**

$C_6H_2Me(NH_2)(SO_3H)_2 2aq$ [1:2:4:*x*]. From $C_6H_3Me(NH_2)(SO_3H)$ [1:2:4] and $ClSO_3H$ at 170° (Saworowicz, *B.* 18, 2181). Minute prisms. At 300° it decomposes into SO_3 and $C_6H_3Me(NH_2)SO_3H$ [1:2:4]. **Salts.**—$BaA''2aq$.—$CaA''2aq$.

***m*-Amido-toluene disulphonic acid**

$C_6H_2Me(NH_2)(SO_3H)_2$ [1:3:2:*x*]. By sulphonation of *m*-toluidine (Lorenz, *A.* 172, 188). Easily splits up into SO_3 and the mono-sulphonic acid.

Salts.—$BaH_2A''_2(?12\frac{1}{2})aq$.—$PbA''2aq$.

***p*-Amido-toluene-disulphonic acid**

$C_6H_2Me(NH_2)(SO_3H)_2$ [1:4:2:3]. From *p*-toluidine and fuming H_2SO_4 at 200° (Pechmann, *A.* 173, 217). Nodules; v. e. sol. water and alcohol.

Salt.—$BaA''3aq$: laminæ.

***p*-Amido-toluene-disulphonic acid**

$C_6H_2Me(NH_2)(SO_3H)_2 2\frac{1}{2}aq$ [1:4:2:*x*]. Formed from $C_6H_3Me(NH_2)(SO_3H)$ [1:4:2] by $ClSO_3H$ at 150° or fuming H_2SO_4 at 180° (L. Richter, *A.* 230, 331). Long silky needles, v. sol. water, sol. alcohol. At 290° it splits up into SO_3 and $C_6H_3Me(NH_2)(SO_3H)$ [1:4:2].

Salts. — $BaA''aq$. — $BaH_2A''_2 1\frac{1}{2}aq$. — $BaH_2A''_2 \frac{1}{2}aq$.—$K_2A''2aq$.—$PbA''1\frac{1}{2}aq$.

***p*-Amido-toluene-disulphonic acid**

$C_6H_2Me(NH_2)(SO_3H)_2 2aq$ [1:4:3:*x*]. Formed from $C_6H_3Me(NH_2)(SO_3H)$ [1:4:3] and H_2SO_4 or $ClSO_3H$ (L. Richter, *A.* 230, 314). Mass of minute needles (from water). With water at 140° (or dry at 200°) it splits up into SO_3 and $C_6H_3Me(NH_2)(SO_3H)$ [1:4:3]. This acid is perhaps identical with that of Pechmann.

Salts.—$BaA''3aq$.—$BaH_2A''_2 3aq$.—$K_2A''2aq$.—PbA''.—$PbA''2aq$.

Diazo derivative $C_6H_2Me(N_2SO_3)''SO_3H$. V. sol. water, insol. alcohol. KA'.—BaA'_2.—PbA'_2.

Hydrazine derivative.—From the diazo acid by $SnCl_2$.

$(C_6H_2Me(N_2H_3)(SO_3H)SO_3)_2Ba\,2\frac{1}{2}aq$.

Reduces HgO, ammoniacal $AgNO_3$, Fe_2Cl_6 and Fehling solution.

Amido-toluene di-sulphonic acid

$C_6H_2(NH_2)Me(SO_3H)_2(?2)aq$. From *p*-bromo-toluene disulphonic acid by nitration, and reduction of the resulting nitro-toluene disulphonic acid (Kornatzki, *A.* 221, 198).

Di-amido-toluene *exo*-sulphonic acid

$C_7H_{10}N_2SO_3$ *i.e.* $C_6H_3(NH_2)_2CH_2SO_3H$. *Di-amido-benzyl-sulphonic-acid.* Formed by reducing $C_6H_3(NO_2)_2CH_2SO_3H$ with NH_3 and H_2S (Mohr, *A.* 221, 228). Silky needles.

Di-amido-toluene sulphonic acid

$C_6H_2Me(NH_2)_2SO_3H$ [1:2:4:5]. Formed from $C_6H_2Me(NO_2)(NH_2)SO_3H$ and $SnCl_2$ (Foth, *A.*

230, 809). Small brownish prisms, rhombohedra (from water). Salts.—HA'HCl aq: prisms, decomposed by boiling water. — HA'HBr aq.— BaA'_2 5½aq.—KA' aq.

o-**AMIDO - TOLUENE - THIO - SULPHONIC ACID** $C_7H_9NS_2O_2$ *i.e.* $C_6H_3Me(NH_2)SO_2SH$ [1:2:4]. From $C_6H_3(NO_2)MeSO_2Cl$ and ammonic sulphide (Limpricht a. Paysan, *A.* 221, 360). Four-sided prisms. Decomposes without melting at 115°. Sl. sol. cold water, insol. alcohol. Warmed with HCl forms S and toluene sulphamine. Salt.—AgA'.

p-**Amido-toluene thio-sulphonic acid** $C_6H_3(NH_2)Me.SO_2SH$ [1:4:5]. Formed from $C_6H_3(NO_2)MeSO_2Cl$ [44°] and ammonic sulphide (Limpricht a. Heffter, *A.* 221, 345). Hard yellowish prisms (from water). Decomposed at 120° without melting. Insol. alcohol or ether, sl. sol. water. Decomposed by HCl with deposition of S and formation of $C_6H_3(NH_2)MeSO_2H$.

Salts: $BaA'_2$2aq.—AgA'.

Di-amido-toluene thiosulphonic acid $C_7H_{10}N_2S_2O_2$ *i.e.* $C_6H_2(CH_3)(NH_2)_2.SO_2SH$. [152°].

Formation.—1. By reduction of di-nitro-toluene-sulphonic chloride with NH_4HS.—2. By reduction of di-nitro-toluene sulphinic acid with NH_4HS. Small silky prisms. V. sl. sol. water, insol. alcohol and ether.

Salts.—A'Ag: white insol. pp.—A'Na: large tables—A'_2Pb: easily soluble (Perl, *B.* 18, 67).

AMIDO-TOLUIC ACIDS $C_8H_9NO_2$. *Amido-toluylic acids.*

(*a*)-**amido-*o*-toluic acid** $C_6H_3Me(NH_2)CO_2H$ [1:4:2]. [196°]. Formed by reducing (*a*)-nitro-*o*-toluic acid (Jacobsen, *B.* 17, 164). Small prisms, v. sol. hot alcohol, and hot water, sl. sol. cold water. Converted by nitrous acid into oxy-toluic acid [172°].

(*β*)-**amido-*o*-toluic acid** $C_6H_3Me(NH_2)CO_2H$ [1:6:2] [191°]. Formed by reducing (*β*)-nitro-*o*-toluic-acid (Jacobsen, *B.* 16, 1959; 17, 164). Small needles, v. sol. cold water. Converted by nitrous acid into oxy-toluic acid [183°].

(*γ*)-**amido-*o*-toluic acid** $C_6H_3Me(NH_2)CO_2H$ [1:5:2]. [153°] (Hoenig, *B.* 18, 3449); [c. 165°] (J.).

Formation.—1. By reducing (*γ*)-nitro-*o*-toluic acid.—2. By heating nitro-phthalide [141°] with HI and P at 205°. Colourless needles; may be sublimed, but at 200° it splits off CO_2 forming *m*-toluidine. V. sol. hot alcohol, m. sol. hot water and ether, sl. sol. chloroform, benzene, and cold water. Nitrous acid produces oxy-toluic acid [179°].

Salts: HA'HCl: slender needles.—×CuA'_2.—$HA'H_2PO_4$: plates.

Amido-*m*-toluic acid $C_6H_3Me(NH_2)CO_2H$ [1:4:3] or [1:4:5].

Formation.—1. The hydrochloride is obtained by warming methyl-isatoic acid with HClAq (Panaotović, *J. pr.* [2] 33, 61).—2. The same acid is got from *m*-toluic acid by nitration and reduction (Jacobsen, *B.* 14, 2354; compare Panaotović, *loc. cit.*).

Properties.—Trimetric, thread-like rods (from water). Sl. sol. water, v. sol. alcohol and ether. Salt: HA'HCl. [207°]. Colourless trimetric prisms; m. sol. water and alcohol, sl. sol. ether.

Methyl ether $C_6H_3Me(NH_2)CO_2Me$. [62°]. From methyl-isatoic acid and MeOH at 180°. Slender columns; sl. sol. water.

Amide $C_6H_3Me(NH_2)CO.NH_2$. [178°]. From methyl-isatoic acid and NH_3Aq. Small columns (from water); v. sol. alcohol.

Anilide $C_6H_3Me(NH_2)CONPhH$. [240°]. Pearly tablets (from alcohol); v. sl. sol water.

Phenyl-hydrazide $C_6H_3Me(NH_2).CO.N_2H_2Ph$. [198°]. From methyl-isatoic acid and phenyl-hydrazine. Pearly crystals (from alcohol); v. sl. sol. water. Forms a violet solution with conc. H_2SO_4.

(*β*)-**Amido-toluic acid** $C_6H_3(CH_3)(NH_2)(CO_2H)$ [1:2:3]. [132°]. Obtained by nitration and reduction of *m*-toluic acid (Jacobsen, *B.* 14, 2354; compare Panaotović, *J. pr.* [2] 33, 61). Small flat prisms; m. sol. water.

Amido-*m*-toluic acid. *Benzoyl derivative* $C_6H_3(NHBz)MeCO_2H$ [5 or 6:1:3]. Formed by oxidation of benzoyl iso-cymidine (Kelbe a. Warth, *A.* 221, 168). Small yellowish needles (from alcohol).

DI-AMIDO-DITOLYL $C_{14}H_{16}N_2$.

Di-amido-ditolyl [4:3:1] $(NH_2)MeC_6H_3.C_6H_3Me(NH_2)$ [1:3:4]. *o-Tolidine.* [112°].

Formation.—1. By passing Cl_2O into an ethereal solution of *o*-hydrazotoluene (Petrieff, *B.* 6, 557).—2. By heating *o*-hydrazo-toluene (Petrieff, *B.* 6, 557).—3. By heating *o*-hydrazo-toluene with HCl (Schultz, *B.* 17, 467).—4. By warming an alcoholic solution of *o*-azo-toluene with $SnCl_2$ and HCl (S.).

Pearly plates; v. sol. alcohol and ether, sl. sol. water. Converted by diazo reaction into *m*-ditolyl. Converted by boiling its diazo-perbromide with alcohol, into a di-bromo-ditolyl, which oxidises to bromo-*m*-toluic acid [1:2:4], [205°]. Salts.—The sulphate and hydrochloride are sparingly soluble in water.

Acetyl derivative $C_{12}H_6Me_2(NAcH)_2$. [315° cor.]

Di-amido-ditolyl. *m-Tolidine.*

The sulphate, $B''H_2SO_4$, separates slowly when a few drops of H_2SO_4 are added to an alcoholic solution of *m*-hydrazotoluene (Goldschmidt, *B.* 11, 1626). The free base has a low melting-point. Gives a blue colour with Fe_2Cl_6.

'**Di-amido-ditolyl.**' [107°]. Formed by the action of SO_2 or of $SnCl_2$ and HCl upon an alcoholic solution of *p*-azo-toluene (Melms, *B.* 3, 554; Schultz, *B.* 17, 472). Silvery plates. Gives a blue colour with Fe_2Cl_6. Fischer (*B.* 25, 1019) has shown this body to be tolylene-tolyl-diamine.

Di-amido-*u*-ditolyl [4:3:1]. $(NH_2)MeC_6H_3.C_6H_3Me(NH_2)$ [1:2:4]?

o-m-Tolidine. Formed by the action of $SnCl_2$ and HCl on an alcoholic solution of *o-m*-azo-toluene. By diazotisation in alcoholic solution it is converted into a ditolyl of boiling point 270° which on oxidation gives isophthalic acid.

Salts.—$B''H_2Cl_2$: easily soluble silky needles. —$B''H_2SO_4$×: very sparingly soluble plates (Schultz, *B.* 17, 471).

AMIDO-TOLYL-BENZAMIDINE $C_{14}H_{15}N_3$ *i.e.* $NH_2.C_6H_3Me.NH.C(NH).C_6H_5$ [212°]. From benzonitrile and (1:2,4)-tolylene-diamine hydrochloride (Bernthsen a Trompetter, *B.* 11, 1758). White needles.—B'HCl: prismatic tables.

AMIDO-TOLYL-ISO-BUTANE $C_{11}H_{17}N$ *i.e.* $C_6H_3Me(C_4H_9)NH_2$ [1:5:2]. (243°). From *o*-

toluidine and isobutyl alcohol (Effront, *B.* 17, 2320). Salts.—B'HCl.—B'HBr.—$B'_2H_2SO_4$.—$B'_2H_2C_2O_4$.

Acetyl derivative [162°]. Plates.

Benzoyl derivative [168°]. Needles.

Amido-tolyl-isobutane $C_6H_3Me(C_4H_9)NH_2$ [1:3:2]. (244°). From *o*-toluidine, isobutyl alcohol, and $ZnCl_2$ (Erhardt, *B.* 17, 419; Effront, *B.* 17, 2340). *Formyl derivative* [105°].

Acetyl derivative [142°].

***o*-AMIDO-TOLYL-ETHANE** $C_9H_{13}N$ *i.e.* $C_6H_3Me(NH_2)Et$ (230°). *Methyl-ethyl-phenyl-amine. Amido-ethyl-toluene.* From *o*-toluidine, alcohol, and $ZnCl_2$ at 270° (Benz, *B.* 15, 1650). Salts.—$B'_2H_2SO_4$.—$B'_2H_2C_2O_4$.

Acetyl derivative [106°]. (314°).

DI-AMIDO-DI-TOLYL-ETHYLENE DIAMINE *v.* DI-TOLYLENE-ETHYLENE-TETRA-AMINE.

AMIDO-TOLYL MERCAPTANS C_7H_9NS. *Amido-thio-cresols. Amido-tolyl sulphydrate.* Prepared by reducing the chlorides of the corresponding nitro-toluene sulphonic acids (Hess, *B.* 14, 488).

Amido-*o*-tolyl mercaptan $C_6H_3Me(NH_2).SH$ [1:4:2]. [42°]. Sol. alcohol, ether, alkalis, and acids; oxidised by air.

Salt.—B'HCl: prisms or tables.

Acetyl derivative [195°]: slender needles; insol. HCl.

Amido-*m*-tolyl mercaptan $C_6H_3Me(NH_2)SH$ [1:4:3]. Oil; oxidised in air gives with $HgCl_2$ a white crystalline pp.; with $Pb(OAc)_2$ a yellow amorphous pp. Gives anhydro compounds with formic acid, acetic anhydride, and benzoyl chloride.

Amido-*p*-tolyl mercaptan $C_6H_3Me(NH_2)SH$ [1:2:4]. Oil. Oxidised by air to the disulphide.

Salt.—B'HCl: short needles.

Acetyl derivative [240°].

Amido-tolyl mercaptan $C_6H_3Me(NH_2)SH$ [1:2: ?] From *o*-nitro-toluene sulphochloride [36°]. Oil.

Salt.—B'HClaq: six-sided tables. Gives with Fe_2Cl_6 a pp. of the disulphide. $HgCl_2$ gives glistening plates, and alkaline lead acetate gives a yellow pp.

AMIDO-TOLYL METHYL KETONE $C_9H_{11}NO$ *i.e.* [1:2:5] $C_6H_3(CH_3)(NH_2).CO.CH_3$ [102°]. (280°-284°). Prepared by heating a mixture of *o*-toluidine (1 pt.), $ZnCl_2$ (2 pts.), and acetic anhydride (3 or 4 pts.), for 8 or 9 hours (Klingel, *B.* 18, 2696). Flat white needles. V. sol. alcohol, ether, and hot water, v. sl. sol. benzene and petroleum-ether. Salts.—B'HCl: flat white soluble prisms.—$B'_2H_2Cl_2PtCl_4$: yellow needles, v. sol. alcohol, sl. sol. hot water, insoluble ether.—$B'_2H_2SO_4$: white needles.

Acetyl derivative $C_6H_3Me(CO.Me)(NHAc)$, [144°]; white crystals; v. sol. alcohol and warm water.

AMIDO-TOLYL-(*aa*)-DIMETHYL-PYRROL $C_4NH_2Me_2C_7H_6NH_2$. [73°]. (322°). Obtained by heating its dicarboxylic acid (*v. infra*).

***m*-AMIDO-TOLYL-(*aa*)-DI-METHYL-PYRROL (*ββ*)-DICARBOXYLIC ACID** $C_{15}H_{16}N_2O_4$ *i.e.* $C_4NMe_2(C_7H_6NH_2)(CO_2H)_2$. From *m*-tolylene diamine and diacetyl-succinic ether (Knorr, *A.* 236, 313). Yellow plates (containing 2aq). At 203° it gives CO_2 and *m*-amido-tolyl-(*aa*)-di-methyl-pyrrol. Ether Et_2A'' [134°].

AMIDO-TOLYL-OCTANE $C_{15}H_{25}N$ *i.e.* $C_6H_3Me(NH_2)C_8H_{17}$. [325°]. From *n*-octyl alcohol, *o*-toluidine, and $ZnCl_2$ at 280° (Beran, *B.* 18, 145). Salts.—B'HCl.—$B'_2H_2SO_4$.—$B'_2H_2C_2O_4$.

Acetyl derivative [81°].

DI-AMIDO-DI-TOLYL-OXAMIDE *v.* *Oxalyl-*DI-TOLYLENE-TETRA-AMINE.

AMIDO-TOLYL SULPHYDRATE *v.* AMIDO-TOLYL MERCAPTAN.

DI-AMIDO-DI-TOLYL SULPHIDE $C_{14}H_{16}N_2S$ *i.e.* $(C_6H_3MeNH_2)_2S$ [1:4:2]. *Thio-toluidine.* [103°]. Prepared by heating *p*-toluidine, sulphur, and litharge together at 150° (Merz a. Weith, *B.* 4, 393). Laminæ (from alcohol); sl. sol. water.

Salts.—Decomposed by water.—B''2HCl sl. sol. conc. HClAq.—$B''H_2PtCl_6$.—$B''H_2SO_4$.—$B''H_2SO_4$ 2aq. — $B''H_2Br_2$. — $B''H_2I_2$. — $B''(C_6H_2(NO_2)_3OH)_2$ [179°]: silky yellow needles (from benzene); v. sl. sol. ether and cold water.

Diacetyl derivative [211°].

Dibenzoyl derivative [186°] (Truhlar, *B.* 20, 664).

Di-amido-di-*p*-tolyl sulphide *ν*-carboxylic ether $S(C_6H_3Me.NH.CO_2Et)_2$. *Thio-p-tolyl urethane* [113°]. From the preceding and $ClCO_2Et$. Crystals; v. sol. alcohol, ether, and benzene (T.).

AMIDO-TOLYL-UREA $C_8H_{11}N_3O$ *i.e.* $NH_2.CO.NH.C_6H_3Me.NH_2$. Formed, in small quantity, by the action of tolylene diamine sulphate on potassium cyanate (Strauss, *A.* 148, 159). V. sol. alcohol.

Di-amido-di-*p*-tolyl-urea $CO(NH.C_7H_6.NH_2)_2$. Formed by reducing the corresponding nitro-compound (A. G. Perkin, *C. J.* 37, 700). Minute satiny needles; sl. sol. alcohol.—B''2HCl.

AMIDO-TYROSINE $C_9H_{12}N_2O_3$ *i.e.* $C_6H_3(OH)(NH_2).C_2H_3(NH_2).CO_2H$. From nitro-tyrosine (Beyer, *Bl.* 1867, ii. 369). Crystalline powder; v. sol. water, sl. sol. alcohol.

Salts.—$B''H_2Cl_2aq$.—$B''H_2SO_4$.—$B''2H_2SO_4$.—$(B''H_2SO_4)_2ZnSO_4$.

AMIDO-URAMIDO-BENZOIC ACIDS $C_8H_9N_3O_3$ *i.e.* $NH_2.CO.NH.C_6H_3(NH_2).CO_2H$. Prepared by reducing the two nitro-uramido-benzoic acids (Griess, *B.* 5, 195).

(*a*)-Acid. Plates; sl. sol. water, v. sl. sol. alcohol. Salts.—HA'HCl.—AgA'.

(*β*)-Acid. Plates; m. sol. hot water. Forms no hydrochloride. Boiling aqueous baryta or HCl forms NH_3 and amido-carboxamido-benzoic acid, of which the barium salt, $Ba(C_8H_5N_2O_3)_2$ 4aq crystallises in needles.

(*a*)-AMIDO-UVITIC ACID $C_9H_9NO_4$ *i.e.* $C_6H_2(NH_2)(CH_3)(CO_2H)_2$ [2:1:3:5] (?). Colourless solid. Sl. sol. water. Prepared by reduction of (*a*)-nitro-uvitic acid (Böttinger, *B.* 13, 1933).

(*β*)-Amido-uvitic acid [c. 255°] (Böttinger, *B.* 9, 807).

AMIDO-VALERIC ACIDS $C_5H_{11}NO_2$.

***a*-Amido-*n*-valeric acid** $CH_3.CH_2.CH_2.CH(NH_2).CO_2H$.

Formation.—1. From *n*-butyric aldehyde-ammonia and aqueous HCN (Lipp, *A.* 211, 359). 2. From its benzoyl derivative which occurs among the products of oxidation of benzoyl-coniine (Baum, *B.* 19, 506).—3. From bromo-valeric acid and NH_3Aq at 130° (Juslin, *Bl.* [2] 37, 3).

Properties.—White glistening plates; v. sol. water, sl. sol. alcohol, insol. ether; may be sublimed. Has a sweet taste. Is optically inactive. Neutral to litmus.

Salts. — HA'HCl: needles or groups of prisms; only deliquescent in very moist air. —$HA'HNO_3$. — $(HA'HCl)_2PtCl_4$. — CuA'_2: small blue plates, sl. sol. water, insol. alcohol.—AgA': crystalline pp., sl. sol. water.

γ-Amido-valeric acid $CH_3.CH(NH_2).CH_2.CH_2.CO_2H$. [193° uncorr.]. Obtained by reduction of the phenyl-hydrazide of β-aceto-propionic acid— $CH_3.C(N_2HPh).CH_2.CH_2.CO_2H$ in alcoholic solution with sodium amalgam and acetic acid (Tafel, *B.* 19,2415; 20,249). White plates. V. sol. water, nearly insol. alcohol, insol. benzene and ether. On heating it splits off H_2O and the anhydride distils. The **hydrochloride** forms glistenin plates, easily soluble in alcohol.

Anhydride

$$\begin{array}{l}\qquad\ \ \mathrm{NH}\text{————}\urcorner\\ \mathrm{CH_3.\dot{C}H.CH_2.CH_2.\dot{C}O.}\end{array}$$

Oxy-methyl-pyrrol di-hydride. (248° i.V.) at 743 mm. colourless liquid which solidifies in a freezing mixture. V. sol. water, alcohol, ether, and benzene. Its **nitrosamine** is a yellow oil.

α-Amido-iso-valeric acid $(CH_3)_2CH.CH(NH_2).CO_2H$.

Formation.—1. From NH_3 and α-bromo-iso-valeric acid (Cahours, *A. Suppl.* 2, 83; Fittig a. Clark, *A.* 139, 199; Schmidt a. Sachtleben, *A.* 193, 105) or α-chloro-iso-valeric acid (Schlebusch, *A.* 141, 326).—2. From its nitrile (Lipp, *A.* 205, 18; *B.* 13, 905).

Properties.—Colourless laminæ, composed of minute monoclinic prisms; v. sol. water, v. sl. sol. cold alcohol or ether. Neutral. May be sublimed.

Salts. — HA'HCl: large tables, not deliquescent in moist air. — $HA'HNO_3$. — CuA'_2: scales, sl. sol. hot water. — AgA': spherical groups of crystals, v. sl. sol. water.

Amide $Me_2CH.CH(NH_2).CO.NH_2$. The **hydrochloride**, got by action of fuming HCl on the nitrile, forms monoclinic plates, v. sol. water. —$(B'HCl)_2PtCl_4$: prisms.

Nitrile $Me_2CH.CH(NH_2).CN$. From iso-butyric aldehyde - ammonia and HCN (L.). Yellow oil; m. sol. water, v. sol. alcohol and ether; gradually changes to imido-di-valero-nitrile, $NH(CHPr.CN)_2$, giving off NH_3. **Salts.**— B'HCl: insol. ether.—$(B'HCl)_2PtCl_4$.

β-Amido-*iso*-valeric acid $(CH_3)_2C(NH_2).CH_2.CO_2H$aq [c. 215°].

Formation.—1. Among the products of oxidation of the sulphate of diacetonamine (Heintz, *A.* 198, 51).—2. By reduction of β-nitro-iso-valeric acid (Bredt, *B.* 15, 2321).

Properties.—Crystalline powder; begins to sublime at 180°. V. e. sol. water, sl. sol. alcohol, insol. ether.

Salts.—HA'HClaq: needles, [c. 120°].— $(HA'HCl)_2PtCl_4$. — $CuA'_2$2aq: large crystals.— AgA'.—$(AgA')_2AgNO_3$aq.

Amido-valeric acid $C_5H_9(NH_2)O_2$. Found in the radicles of the sprouting lupin seeds. It occurs along with amido-phenyl-propionic acid, from which it may be separated by virtue of the greater solubility of its copper salt (Schulze a. Barbieri, *J. pr.* [2] 27, 352).

Properties. — Glittering plates, resembling leucine (from alcohol). When heated, a woolly substance sublimes out of it. Gives no pp. with cupric hydrate or acetate (difference from leucine). **Salt.**—HA'HCl: deliquescent prisms.

Constitution. — Probably identical with Lipp's α-amido-*n*-valeric acid (*A.* 211, 354).

Amido-valeric acid. Occurs in the pancreas of oxen (Gorup-Besanez, *A.* 98, 15). Prisms; v. sl. sol. alcohol (difference from leucine). The **hydrochloride** forms slender deliquescent needles. An amido-valeric acid was found by Schützenberger (*A. Ch.* [5] 16, 283) among the products of the decomposition of albumen by baryta-water.

AMIDO-VERATRIC ACID *v.* *di-methyl-di-*OXY-AMIDO-BENZOIC ACID.

AMIDOXIMS. *Oxy-amidines. Oxy-imidgamides.* The oxims of amides, the general formula being $R.C(NOH).NH_2$.

Formation.—1. By action of hydroxylamine upon nitriles: $R.CN + N(OH)H_2 = R.C(NOH).NH_2$. 2. By heating the thio-amides with alcoholic solution of hydroxylamine (Tiemann, *B.* 19, 1668): $R.CS.NH_2 + H_2.NOH = R.C(NOH).NH_2 + H_2S$.

Properties.—The amidoxims combine with acids; they also contain hydrogen displaceable by metals. The acid salts of the alkaline metals, $RC(NOK).NH_2,RC(NOH).NH_2$ crystallise well. The stability is increased by the presence of electro-negative substituents; thus, nitro-benz-amidoxim can be reduced to amido-benz-amidoxim without destruction of the amidoxim group.

Ethers.—$R.C(NOEt).NH_2$. These are formed by the action of iodide of ethyl (or of other alkyls) upon the alkaline salts, such as $R.C(NOK).NH_2$. They are bases.

Reactions.—1. Split up by treatment with *acids* or *alkalis* into NH_3, hydroxylamine, and the corresponding acid: $R.C(NOH).NH_2 + 2H_2O = R.CO.OH + H_2NOH + NH_3$. This reaction takes place most readily with methenyl-amidoxim (isuretine) and ethenyl-amidoxim, while benzenyl-amidoxim requires long boiling with HCl before it is decomposed. In this saponification of amidoxims the amide seems to be first formed: $R.C(NOH).NH_2 + H_2O = R.CO.NH_2 + H_2NOH$.—2. The hydrochlorides are converted by *sodium nitrite* into amides: $R.C(NOH).NH_2HCl + NaNO_2 = R.CO.NH_2 + NaCl + N_2O + H_2O$.—3. They combine with *phenyl cyanate* forming bodies called uramidoxims; *e.g.*: $Ph.C(NOH).NH_2 + PhNCO = Ph.C(NOH).NH.CO.NHPh$.—4. *Chlorides of acid radicles*, $R'.CO.Cl$, form alkoyl derivatives, $R.C(N.O.CO.R').NH_2$, which can split off water forming **azoxims** $R.C\Big\langle\!\begin{smallmatrix}N.O\\N\end{smallmatrix}\!\Big\rangle CR$. These azoxims, although of high boiling point, are extremely volatile in the vapour of other liquids, even ether.—5. *Dibasic organic anhydrides* give rise to carboxylic acids of azoxims, *e.g.*: $R'.C(NOH).NH_2 + R''\Big\langle\!\begin{smallmatrix}CO\\CO\end{smallmatrix}\!\Big\rangle O = R'.C\Big\langle\!\begin{smallmatrix}N.O\\N\end{smallmatrix}\!\Big\rangle C.R''.CO_2H + H_2O$.—6. *Chloroformic ether* produces bodies of the composition $R.C(NH_2):N.O.CO_2Et$.—7. *Carbonyl chloride* gives carbonyl-di-oxims, $(R.C(NH_2):N.O)_2CO$.— 8. *Chloral* forms crystalline addition-products.

References.—Tiemann, *B.* 18, 1060, 2456;

19, 1475. The Amidoxims are described as Formamidoxim, Ethenyl-amidoxim, Hexoamidoxim, Benzamidoxim, Cinnamidoxim, Toluamidoxim, Benzamidoxim carboxylic acid, Nitro-benzamidoxim, &c.

AMIDO-XYLENE *v.* Xylidine.

Exo-**Amido-xylene** $CH_3.C_6H_4.CH_2.NH_2$ [1:3?]. (196°). From $CH_3.C_6H_4.CH_2Cl$ and alcoholic NH_3 (Pieper, *A.* 151, 120). Oil. Salts.—B'HCl [185°].—$B'_2H_2PtCl_6$.

Exo-**Amido-*p*-xylene** $CH_3.C_6H_4.CH_2.NH_2$ [1:4]. From $CH_3.C_6H_4.CS.NH_2$, tin, and HCl (Paterno a. Spica, *B.* 8, 441).

di-Amido-xylene *v.* Xylylene diamine.

tri-Amido-xylene $C_8H_{13}N_3$ *i.e.* $C_6HMe_2(NH_2)_3$ [1:3:4:6:2]. Formed by reducing tri-nitro-*m*-xylene [177°] (Greving, *B.* 17, 2427). White needles which may be sublimed.

AMIDO-XYLENE-SULPHONIC ACID $C_8H_{11}NSO_3$.

Amido-xylene sulphonic acid $C_6H_2(NH_2)Me_2SO_3H$ [4:1:3:6]. S. ·276 at 0°; ·735 at 100°. From (1,3,4)-xylidine and H_2SO_4 or from nitro-*m*-xylene sulphonic acid (Jacobsen a. Ledderboge, *B.* 16, 193). Salts.—NaA'aq and KA'aq form large trimetric tables.—BaA'_2aq: minute needles, v. sol. water.—$BaA'_2$2aq (Sartig, *A.* 230, 334; Nölting a. Kohn, *B.* 19, 137). Diazo compound $C_6H_2Me_2N_2SO_3$: plates.

Amido-*p*-xylene sulphonic acid $C_6H_2Me_2(NH_2)(SO_3H)$ [1:4:6:2]. From *p*-xylene sulphonic acid by nitration and reduction (Nölting a. Kohn, *B.* 19, 143). Needles (with aq): sl. sol. cold water. Its salts are easily soluble. Does not give xyloquinone on oxidation.

Amido-*p*-xylene sulphonic acid $C_6H_2Me_2(NH_2)SO_3H$ [1:4:2:5]. From amido-*p*-xylene and fuming H_2SO_4 or by heating its acid sulphate at 230°. Readily oxidised by CrO_3 to xyloquinone. Salts.—NaA': plates, v. sol. water.—$BaA'_2$7aq (Nölting, *B.* 18, 2664; 19, 141).

Di-amido-xylene sulphonic acid $C_6HMe_2(NH_2)_2SO_3H$ [1:3:6:?:4]. From nitro-xylidine sulphonic acid and ammonium sulphide (Limpricht, *B.* 18, 2190; Sartig, *A.* 230, 343). Fawn-coloured prisms, sl. sol. water, insol. alcohol. Fe_2Cl_6 colours the solution wine-red. Salts: $BaA'_2$3½aq.—KA'aq.—PbA'_2.—HA'HClaq.

AMIDO-*m*-XYLENOL $C_8H_{11}NO$ *i.e.* $C_6H_2Me_2(NH_2)(OH)$ [1:3:*x*:*y*]. [161°]. Got by reducing nitro-xylenol (Pfaff, *B.* 16, 1137). White glistening crystals. Salt: B'HCl: plates.

Amido-*p*-xylenol $C_6H_2(CH_3)_2(NH_2)(OH)$ [1:4:3:6]. [242°]. White scales. Formed by reduction of nitroso-*p*-xylenol (phlorone-oxim) with tin and HCl (Goldschmidt a. Schmid, *B.* 18, 570; Sutkowski, *B.* 20, 979). CrO_3 oxidises it nearly quantitatively to phlorone.

Salt: B'HCl: white crystals.

AMINES. An amine is a body obtained by displacing hydrogen in ammonia by one or more alcohol radicles. They may be divided into mono-, di-, tri-, and tetra- amines according as it is considered that their molecule is derived from one, two, three, or four molecules of ammonia. Monamines are spoken of as primary, secondary, or tertiary, according as one, two, or three of the atoms of hydrogen in the molecule of ammonia is held to have been displaced by one or more alkyls. If part of the hydrogen has been displaced by an acid radicle (alkoyl) and part by an alcoholic radicle (alkyl) the product may be viewed either as an amide or as an amine, thus NMeAcH may be called methyl-acetamide or acetyl-methylamine. In this dictionary the latter name will be used, such derivatives being described under the amines from which they may be held to be derived. Fatty amines are amines in which the nitrogen is attached to carbon that does not form part of a ring; aromatic amines are bases in which the nitrogen is attached to carbon in a benzene nucleus. In addition to these there are amines, such as pyridine and quinoline, in which the nitrogen itself forms part of a ring, and also others in which the nitrogen is united to carbon in rings other than that peculiar to benzene.

Formation.—1. By the action of ammonia on the ethers of inorganic acids. The iodides, bromides, and chlorides of fatty, but not of aromatic, alkyls, combine with ammonia and with the amines (Hofmann, *T.* 1850, i. 93; 1851, ii. 357):

$$NH_3 + EtI = NEtH_3I$$
$$NEtH_2 + EtI = NEt_2H_2I$$
$$NEt_2H + EtI = NEt_3HI$$
$$NEt_3 + EtI = NEt_4I.$$

The fatty alkyl iodides also act upon the hydriodides of the amines, in presence of ammonia:

$$NH_3 + NEtH_3I + EtI = NEt_2H_2I + NH_4I$$
$$NH_3 + NEt_2H_2I + EtI = NEt_3HI + NH_4I$$
$$NH_3 + NEt_3HI + EtI = NEt_4I + NH_4I.$$

It is therefore impossible to prepare a pure base by this method; methyl iodide gives chiefly NMe_4I, while ethyl iodide gives chiefly $NEtH_3I$, but in the case of primary iodides, whatever proportions are taken, the entire series of salts is formed. Isobutyl iodide does not form the quaternary iodide, secondary butyl iodide forms hardly any tri-butylamine, but only mono- and di-butylamine, while tertiary butyl iodide is split up by NH_3 into isobutylene and HI. NEt_3 at 100° splits up isopropyl iodide and tertiary butyl iodide forming NEt_3HI and olefine (Hofmann, *B.* 7, 513; Reboul, *C. R.* 93, 69). Secondary propyl, hexyl, and octyl iodides form only mono-amines when heated with ammonia (Jahn, *M.* 3, 165). In the action of alkyl chlorides upon aqueous NH_3, the higher the molecular weight, the less primary amine is formed (Malbot, *C. R.* 104, 998).

Ammonium iodide can be separated by its insolubility in alcohol. The compounds NR_3HI, NR_2H_2I, and NRH_3I are decomposed by KOHAq with formation of KI and NR_3, NR_2H, or NRH_2 respectively, while tetra-alkylated ammonium iodides are not affected. The following method may be employed in the preparation of fatty amines (Hofmann, *B.* 3, 776). The alkyl iodide, RI, is heated with alcoholic NH_3 at 100°; the product is filtered from NH_4I, evaporated, and distilled with potash. NR_4I remains behind. The distillate, dried by means of solid KOH, is cooled and treated with oxalic ether which is slowly added. The following reactions then occur:

$$EtO.CO.CO.OEt + 2NRH_2 =$$
$$HRN.CO.CO.NRH + 2HOEt$$
$$EtO.CO.CO.OEt + NR_2H =$$
$$EtO.CO.CO.NR_2 + HOEt.$$

The reaction is completed by heat, and the tertiary base, NR_3, which does not react with oxalic ether, is distilled off. The residue is well cooled and the solid di-alkyl oxamide separated from the liquid di-alkyl-oxamic ether by pressure. The latter is purified by washing with water. Boiling potash liberates the alkylamine from the di-alkyl oxamide and the di-alkyl-amine from the di-alkyl-oxamic ether.

When the halogen is situated in a benzene nucleus ammonia cannot effect its displacement by amidogen unless other chlorous groups are also present in the nucleus. Thus *o*- and *p*-chloro-nitro-benzene (but not *m*-chloro-nitro-benzene) are converted into nitro-anilines by alcoholic NH_3 at 100°.

Primary monamines may be prepared by acting with KOH on the alkyl ammonium sulphates (Morrison, *Pr. E.* 28, 693):

$$MeNH_4SO_4 + 2KOH = K_2SO_4 + MeNH_2 + 2H_2O.$$

2. By boiling alkyl cyanates with potash (Wurtz, *C. R.* 28, 223), thus: $EtNCO + H_2O = EtNH_2 + CO_2$. The primary bases prepared by this reaction may be contaminated with secondary and tertiary bases. This occurs when the potassic cyanate used to prepare the alkyl cyanates contains cyanide (Silva, *C. R.* 64, 299).

3. Similarly, from thiocarbimides and H_2SO_4: $EtNCS + H_2O = EtNH_2 + COS$.

4. By the reduction of nitro compounds: $RNO_2 + 3H_2 = RNH_2 + 2H_2O$. This reaction is chiefly used in the aromatic series, inasmuch as it is easy to prepare nitro derivatives of compounds containing a benzene nucleus.

The following reducing agents may be used:

(*a.*) Alcoholic *ammonium sulphide.* The compound is dissolved in alcohol, saturated with NH_3 and H_2S is then passed in. The solution is boiled, filtered from S, acidified, and evaporated; a salt of the base is then left: $C_6H_5NO_2 + 3H_2S = C_6H_5NH_2 + 2H_2O + S_3$ (Zinin, *A.* 44, 283). This method is especially useful in reducing nitro-azo compounds which would give hydrazo compounds if reduced in acid solution.

Substances containing several nitroxyls usually have only one of them reduced when treated in this way.

(*b.*) *Zinc dust* may be used either alone, by mixing the substance with it and distilling, or it may be used in conjunction with water or aqueous potash: $Zn + 2KOH = K_2ZnO_2 + H_2$.

(*c.*) *Ferrous sulphate and aqueous ammonia* are used in reducing unsaturated and unstable compounds.

(*d.*) *Arsenious acid* and NaOHAq.

(*e.*) *An acid and a metal.* For the acid, HClAq or HOAc is used; for the metal, zinc, tin, or iron, is taken. Tin and HClAq give, as a rule, the best results. A mixture of zinc and tin is as effective as pure tin, for the zinc pps. the tin as fast as it dissolves. The amount of acid used may sometimes be very small; thus, in the preparation of aniline, the action seems to be:

$$4C_6H_5NO_2 + 4H_2O + 9Fe = 4C_6H_5NH_2 + 3Fe_3O_4.$$

(*f.*) *Stannous Chloride.* In reducing with $SnCl_2$ and HCl the resulting $SnCl_4$ sometimes chlorinates the product; thus *o*-nitro-toluene gives chloro-*o*-toluidine. The nitroxyls of poly-nitro derivatives may be reduced one by one by adding to their cold alcoholic solution the calculated quantity of $SnCl_2$ dissolved in alcohol saturated with HCl. In the case of dinitro-toluene $C_6H_3Me(NO_2)_2$ [1:2:4] the nitroxyl in the *o* position is first reduced, forming $C_6H_3Me(NH_2)(NO_2)$ [1:2:4]; whilst alcoholic ammonium sulphide reduces the nitroxyl in the *p* position, forming $C_6H_3Me(NO_2)(NH_2)$ [1:2:4] (Anschütz a. Heusler, *B.* 19, 2161).

(*g.*) *Hydric iodide solution*, alone, or with addition of phosphorus.

5. By the reduction of nitriles (Mendius, *A.* 121, 229): $CH_3CN + 2H_2 = CH_3.CH_2.NH_2$.

The reduction is effected by Zn and dilute H_2SO_4 but it is slow, and a great deal of nitrile is saponified: $CH_3.CN + 2H_2O = CH_3.CO_2NH_4$.

6. Primary bases are instantly formed when carbamines are treated with acids:

$$CH_3NC + 2H_2O = CH_3NH_2 + HCO_2H.$$

7. By boiling bromo-amides with aqueous NaOH. If bromine and potash be simultaneously supplied to an amide, a potassium bromo-amide, X.CO.NKBr, is formed. If this compound be treated with silver carbonate, an alkyl cyanate is produced: X.CO.NKBr = KBr + X.N.CO.

When this cyanate is boiled with potash an alkylamine is formed (by *Formation* 2). The two last stages may be performed simultaneously by boiling the potassium bromo-amide with aqueous NaOH.

The operation is conducted as follows:

Bromine is mixed with its equivalent of amide, and a 10 p.c. solution of potash is added till the colour of the bromine has nearly disappeared.

$$X.CO.NH_2 + Br_2 + 2KHO = X.CO.NKBr + KBr + 2H_2O.$$

Three equivalents of potash dissolved so as to form a 30 p.c. solution are now heated to 70° in a retort, and the first solution is added gradually through the tubulus. Finally the whole is distilled, and the base collected in a receiver containing hydric chloride. A mixture of ammonium chloride and the hydro-chloride of the base is thus got; they may be separated by alcohol, which does not dissolve the former (Hofmann, *B.* 15, 765).

8. Amides can be converted into amines by heating with alcohols: thus acetamide and ethyl alcohol give ethylamine acetate $CH_3.CO.NH_2 + HOEt = CH_3.CO.ONEtH_3$, while ethyl-acetamide and ethyl alcohol give diethyl-amine acetate (Baubigny, *C. R.* 95, 646).

$$CH_3.CO.NEtH + HOEt = CH_3CO.ONEt_2H_2.$$

Sodium alcoholates act similarly (Seifert, *B.* 18, 1355):

$$X.NH.CO.Y + NaOR = X.NH.R + NaO.CO.Y.$$

9. From amido-acids by heating alone or with baryta: $C_6H_4(NH_2)CO_2H = C_6H_5NH_2 + CO_2$.

10. From alcohols or phenols by displacing hydroxyl by amidogen. Ethyl and methyl alcohols give a little ethyl- and methyl-amine when heated with NH_4Cl at 300° (Weith, *B.* 8, 459). Similarly, phenols produce small quantities of amines when heated with NH_3; this reaction takes place very readily in the naphthalene and anthracene series. *Ortho*- and *para*-, but not *meta*-, nitro-phenols are converted by aqueous ammonia into nitranilines (Merz a. Riz, *B.* 19, 1749). The reaction takes place more readily when the alcohols are heated at 260° with the compound $ZnCl_2NH_3$ or $CaCl_2NH_3$ (Merz a. Weith, *B.* 13, 1300; 14, 2343; Merz a.

Gasiorowski, *B.* 17, 628; Merz a. Buch, *B.* 17, 2034). Ammonia-zinc-chloride converts phenol into aniline; aniline-zinc-chloride acting upon phenol gives di-phenylamine. β-naphthol is converted by heating with NH_3 into naphthyl-amine, but by ammonia-zinc-chloride into di-β-naphthyl-amine. Fatty alcohols act differently upon aromatic bases in presence of $ZnCl_2$, the alkyl entering the nucleus; thus aniline-zinc-chloride and alcohol produce amido-phenyl-ethane:

$$C_6H_5NH_2 + HOEt = C_6H_4EtNH_2 + H_2O.$$

11. By reduction of the phenyl-hydrazides of the aldehydes and ketones in alcoholic solution by sodium-amalgam and acetic acid (Tafel, *B.* 19, 1924):

$$RR'C{:}N_2HPh + 2H_2 = RR'CH.NH_2 + PhNH_2.$$

12. By reduction of aldoxims and ketoxims in alcoholic solution by sodium amalgam and acetic acid (Goldschmidt, *B.* 19, 3232):

$$RR'C{:}NOH + 2H_2 = RR'CH.NH_2 + H_2O.$$

13. From sulphonates by heating with sodamide (Jackson a. Wing, *B.* 19, 902):

$$R.SO_3K + NaNH_2 = R.NH_2 + NaKSO_3.$$

Properties.—Most amines are volatile or can be distilled alone or with the aid of steam. Primary bases in which amidogen is not united to carbon in a benzene nucleus turn red litmus paper blue and combine with carbonic acid; aniline and its homologues are neutral to litmus, and do not combine with carbonic acid. Ammonia pps. the amines from cold aqueous solutions of their salts; but at high temperatures the amines expel NH_3 from its salts. The relative saponifying power of amines has been studied by Ostwald (*J. pr.* [2] 35, 112). If a mixture of aromatic bases is dissolved in an excess of glacial acetic acid, and the solution is diluted with three times its volume of water and then boiled, the primary amines remain in solution while the acetates of secondary and tertiary amines are decomposed and the bases are found on the filter (Michael, *B.* 19, 1391). To determine whether a given base is primary, secondary, or tertiary, it is heated with methyl iodide until a quaternary iodide is formed; this iodide is known by its stability towards potash. The original base and the ammonium iodide are both analysed. If the ammonium iodide differs in composition by containing CH_3I more than the base, then the base was tertiary. If it differ by C_2H_5I, this shows that the original base was secondary, and had to exchange hydrogen for methyl before it could become tertiary. If the iodide contains C_3H_7I more than the base, then the latter was primary.

Reactions 1, 2, 3, 4, 5, 6, 11, 12, 15, 20, 27, 28, may also be used to distinguish between primary, secondary, and tertiary bases.

When a quaternary ammonium base is distilled, if it contains ethyl it splits up thus:

$$NRR'R''C_2H_5(OH) = NRR'R'' + C_2H_4 + H_2O;$$

(Hofmann, *B.* 14, 494).

Quaternary ammonium chlorides containing methyl split off MeCl on distillation:

$$NRR'R''MeCl = NRR'R'' + MeCl;$$

(Lossen, *A.* 181, 377).

Reactions 3, 5, 6, 12, 13, 26, and 28, serve to distinguish *o*-diamines from *m*- and *p*- diamines.

Reactions.—1. If a primary base be boiled with *alcoholic potash* and *chloroform* the disgusting odour of the corresponding carbamine will be noticed (Hofmann, *B.* 3, 767):

$$EtNH_2 + CHCl_3 + 3KHO = EtNC + 3KCl + 3H_2O.$$

2. If a primary fatty base be dissolved in alcohol mixed with an equal volume of CS_2, and the liquid be boiled down to half its volume, a thiocarbamate will be formed:

$$2RNH_2 + CS_2 = RNH.CS.S.NRH_3.$$

If the liquid be now boiled with a little aqueous mercuric or ferric chloride a pungent odour of an alkyl mustard oil (or thiocarbimide) will be perceived, thus: $RNH.CS.SNRH_3 + HgCl_2 = HgS + RNCS + NRH_3Cl + HCl$. In the aromatic series the product of the action of alcoholic CS_2 is usually a thio-urea which requires to be treated with P_2O_5 in order to get the thiocarbimide (Hofmann, *B.* 3, 768; 8, 107; Weith, *B.* 8, 461). Mesidine and amido-penta-methyl-benzene give thio-carbimides in addition to smaller quantities of the thio-ureas (Hofmann, *B.* 18, 1827).—3. *Nitrous acid* converts primary fatty amines into alcohols: $RNH_2 + HNO_2 = ROH + N_2 + H_2O$. It converts primary aromatic amines into diazo-compounds: $RNH_2 + HNO_2 = RN_2OH + H_2O$. It converts all secondary bases into nitrosamines, which are neutral substances, volatile with steam: $RR'NH + HNO_2 = RR'N.NO + H_2O$. It cannot act upon tertiary fatty bases, except with elimination of an alkyl. It converts most tertiary aromatic bases into nitroso derivatives, which still possess basic properties:

$$C_6H_5NMe_2 + HNO_2 = C_6H_4(NO)NMe_2 + H_2O.$$

Aromatic nitrosamines are converted into *p*-nitroso derivatives under the influence of acids. $C_6H_5NMe(NO) = C_6H_4(NO).NMeH$. By means of the preceding reactions, nitrous acid may be used to separate secondary from primary and tertiary bases, for the nitrosamines do not combine with acids, and may therefore be extracted from the acid solution by ether, or by distilling with steam: and on reduction they give the secondary base. If the diazo compounds are boiled with water phenols are formed: $RN_2Cl + H_2O = ROH + N_2 + HCl$, while if they are boiled with alcohol, the amidogen is usually displaced by hydrogen: $RN_2Cl + C_2H_6O = RH + HCl + C_2H_4O$. Frequently, however, boiling with alcohol displaces amidogen by ethoxyl: $C_6Me_4H.N_2Cl + HOEt = C_6Me_4H.OEt + HCl + N_2$ (Hofmann, *B.* 17, 1917). Amidogen may also be displaced by hydrogen by reducing the diazo compound to a hydrazine and boiling the latter with aqueous $CuSO_4$ (Haller, *B.* 18, 90). In order to displace amidogen by chlorine we may distil the platinochloride of the diazo derivative; to displace amidogen by bromine we may boil the perbromide of the diazo derivative with alcohol; to displace it by iodine we may boil the diazo salt with aqueous HI or KI. These operations may be more conveniently performed by the method of Sandmeyer (*B.* 17, 1633, 2650). This method consists in boiling the diazo compounds with cuprous chloride, bromide, iodide, or cyanide.

Examples.—(*a*) 4 g. *m*-nitro-aniline, 7 g. HCl (S.G. 1·17), 100 g. water, and 20 g. of a 10 p.c. solution of cuprous chloride in HClAq are heated to near boiling and 2·5 g. sodic nitrite dissolved in 20 g. water are slowly added, the mixture being well shaken. 4 g. pure *m*-chloro-nitro-benzene is obtained.

(*b*) 12·5 g. crystallised cupric sulphate, 36 g. KBr, 80 g water, 11 g. H_2SO_4 (S.G. 1·8), and 20 g. copper turnings are boiled until the dark colour has nearly disappeared. Aniline (9·3 g.) is now added, and the boiling liquid treated as before with $NaNO_2$ (7 g.) dissolved in water (40 g.). Bromo-benzene passes over on subsequent distillation.

(*c.*) 25 g. crystallised $CuSO_4$, 150 g. water and 28 g. KCN (96 p.c.) are dissolved in hot water. A solution of diazobenzene chloride is run in, this is prepared from 7 g. $NaNO_2$ dissolved in 20 g. water added to a solution of 9·3 g. aniline in 20·6 g. HCl (S.G. 1·17) and 80 g. water. The yield of benzonitrile is 63 p.c. of the theoretical.

In these reactions a double compound between the cuprous salt and the diazo salt is perhaps an intermediate body. Such a double compound has been isolated in the case of β-naphthylamine, $C_{10}H_7N_2BrCu_2Br_2$ (Lellmann a. Remy, *B.* 19, 810). Substitution of amidogen by halogens may also be effected by gradually adding HNO_3 to a hot solution of the amine in HCl, HBr, or HI (Losanitsch, *B.* 18, 39).

Amidogen may be changed into SH by heating the diazotised base with warm alcoholic potassium sulphide. By oxidising the resulting mercaptan with $KMnO_4$ a sulphonic acid is got (Klason, *B.* 20, 349).

Nitrous acid serves to distinguish *o*-, *m*-, and *p*- diamines (*v.* di-Azo-compounds).

4. *Benzoyl chloride* acts on primary and secondary amines:

$$RNH_2 + BzCl = RNBzH + HCl,$$
$$RR'NH + BzCl = RR'NBz + HCl$$

(Hofmann, *B.* 5, 716; Hallmann, *B.* 9, 846). Tertiary aromatic amines heated with it at 200° may exchange alkyl for benzoyl:

$$NPhEt_2 + BzCl = NPhEtBz + EtCl$$

(Hess, *B.* 18, 685).

5. *Acetyl chloride* converts primary and secondary amines into acetyl derivatives.

The di-alkylated tertiary aromatic amines readily allow one of the alkyl groups to be replaced by acetyl when treated with acetyl *bromide*, the alkyl bromide formed converting another portion into quaternary ammonium bromide: $2XNR_2 + AcBr = XNRAc + XNR_3Br$.

The reaction sets in spontaneously, and is completed on gentle warming (Staedel, *B.* 19, 1947).

Primary aromatic amines may be converted into acetyl derivatives by boiling not only with AcCl or Ac_2O but even with glacial HOAc.

The alkoyl derivatives of *o* but not of *m* and *p* aromatic diamines give rise to anhydro compounds:

$$C_6H_4\left\langle\begin{matrix}NH.CO.CH_3\\NH_2\end{matrix}\right. = H_2O + C_6H_4\left\langle\begin{matrix}NH\\N\end{matrix}\right\rangle C.CH_3$$

(Hübner, *A.* 208, 278).

6. *Aldehydes* form products of condensation with amines. Œnanthol is recommended by Schiff (*A.* 159, 158) as a means of distinguishing between the different classes of amines. Primary amines require one equivalent of œnanthol:

$$C_7H_{14}O + PhNH_2 = PhN(C_7H_{14}) + H_2O,$$

while secondary amines require only half as much aldehyde:

$$C_7H_{14}O + 2Me_2NH = (Me_2N)_2(C_7H_{14}) + H_2O.$$

The base is dissolved in benzene and a standard solution of œnanthol in benzene is run in as long as it produces further separation of drops of water.

Tertiary aromatic amines can also condense with aldehydes: $2PhNEt_2 +$ [1:2] $C_6H_4(NO_2).CHO = NO_2.C_6H_4.CH(C_6H_4NEt_2)_2 + H_2O$. Aromatic amines heated with aldehydes and $ZnCl_2$ give tri-substituted methanes (Fischer, *B.* 15, 676).

In order to distinguish whether an aromatic diamine is an *ortho* compound, Ladenburg (*B.* 11, 600) heats its hydrochloride with benzoic aldehyde; if the compound is *ortho* an aldehydine (*q. v.*) is formed and HCl is evolved, while no HCl is evolved in the case of *m* or *p* compounds.

$$R''(NH_2HCl)_2 + 2PhCHO =$$
$$R''(N_2C_2H_2Ph_2)HCl + 2H_2O + HCl.$$

7. *Bromine and aqueous potash* convert primary amines into di-bromamines:
$MeNH_2 + 2Br_2 + 2KOH = MeNBr_2 + 2KBr + 2H_2O$.
Secondary amines, containing one divalent alkyl, behave similarly:
$C_8H_{14}NH + Br_2 + KOH = C_8H_{14}NBr + KBr + H_2O$
but secondary amines containing two monovalent alkyls are split up into an alkylene bromide and a primary alkylamine (Hofmann, *B.* 16, 559).

The di-bromo-amines containing hexyl and its higher homologues are split up by aqueous NaOH into HBr and nitriles:

$$C_7H_{15}CH_2NBr_2 + 2NaOH =$$
$$C_7H_{15}CN + 2NaBr + 2H_2O.$$

Hence amides may be converted first into amines and then into nitriles by treatment with bromine and NaOHAq, the first reaction being:

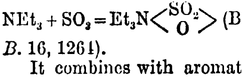
$$C_7H_{15}CH_2.CO.NH_2 + Br_2 + 4NaOH =$$
$$C_7H_{15}CH_2.NH_2 + 2NaBr + Na_2CO_3 + 2H_2O$$

(Hofmann, *B.* 17, 1920).

8. *Sulphuric oxide* combines with primary and secondary fatty amines, forming small quantities of sulphamic acids:

$$NEt_2H + SO_3 = NEt_2.SO_3H.$$

It also combines with tertiary fatty amines:



$NEt_3 + SO_3 = Et_3N\left\langle\begin{matrix}SO_2\\O\end{matrix}\right\rangle$ (Beilstein a. Wiegand, *B.* 16, 1264).

It combines with aromatic amines forming sulphonic acids:

$$C_6H_5NH_2 + SO_3 = C_6H_4(SO_3H)NH_2.$$

Aromatic amines may also be sulphonated by H_2SO_4 and by $ClSO_3H$.

9. *Sulphuryl chloride* acts upon secondary fatty amines thus, forming tetra-alkyl sulphamides: $SO_2Cl_2 + 2HNEt_2 = SO_2(NEt_2)_2 + 2HCl$. With the hydrochlorides of these bases the reaction stops half way: $SO_2Cl_2 + HCl.NHEt_2 = Cl.SO_2.NEt_2 + 2HCl$ (R. Behrend, *A.* 222, 116).

10. *Zinc ethide* does not attack tertiary amines, but acts upon primary and secondary amines in the following ways:

$$2RNH_2 + ZnEt_2 = R_2N_2H_2Zn + 2HEt,$$
$$2RR'NH + ZnEt_2 = R_2R'_2N_2Zn + 2HEt$$

(Frankland, *Pr.* 8, 504; Gal, *C. R.* 96, 578).

11. *Cyanic ethers* unite with primary and secondary bases forming alkyl-ureas:

$$RNH_2 + R'NCO = RNH.CO.NR'H,$$
$$RR''NH + R'NCO = RR''N.CO.NR'H.$$

Cyanic acid acts similarly:

$$RNH_2HCl + KNCO = RHN.CO.NH_2 + KCl$$

12. *Thio-carbimides* unite with primary and secondary amines forming thio-ureas:

$$RNH_2 + R'NCS = RNH.CS.NR'H.$$

When the solid product obtained by boiling an aromatic di-amine with alcohol and oil of mustard (C_3H_5NCS) is gradually heated, then if the diamine were *o* it would solidify above its melting-point; if it were *m* it would melt without further change and would therefore solidify on cooling; if it were *p* it would melt and undergo decomposition and on cooling would remain liquid (Lellmann, *A.* 221, 1; 228, 248; *B.* 19, 808). In all cases di-thio-ureas, $R''(NH.CS.NHC_3H_5)_2$, are first formed; those from *m*-diamines are not affected by heat, while the *o* and *p* derivatives split up on melting thus:

$$R''(NH.CS.NHC_3H_5)_2 = R''{<}\substack{NH\\NH}{>}CS + CS(NHC_3H_5)_2.$$

13. The *di-sulphocyanides* of the *o*-diamines are changed at 120°–130° into thio-ureas, $C_xH_y{<}\substack{NH\\NH}{>}CS$, which are not desulphurised by hot solution of PbO in NaOHAq. The *m* and *p* diamines give compounds of the form $C_xH_y(NH.CS.NH_2)_2$ which are desulphurised by this reagent (Lellmann, *A.* 228, 8, 248).

14. Small quantities of orthodiamines are readily detected by adding a few drops of a hot acetic acid solution of *phenanthraquinone* to an alcoholic solution of the substance; if an orthodiamine is present a yellow crystalline pp. of the corresponding quinoxaline is formed on boiling the solution; this pp. in the case of phenylene and tolylene *o*-diamines is coloured deep-red by HCl (Hinsberg, *B.* 18, 1228).

15. If a mixture of bases is treated with sufficient *citraconic acid* to form the acid salts and the aqueous solution is boiled the primary amines will be ppd. in the form of alkyl-citraconamic acids, while the secondary and tertiary amines can be obtained by distilling the filtrate with steam (Michael, *B.* 19, 1390).

16. *Oxidising agents* convert aromatic amines into azo or azoxy compounds. Hence the nitration of such amines by the usual methods requires previous introduction of acetyl into the amidogen. But by treating the nitrates with cold conc. H_2SO_4 nitro-amines may be prepared, the nitroxyl taking a *m* position with regard to amidogen (Levinstein, *D. P. J.* 256, 471).

17. Amines form condensation products with *quinones*, *e.g.*

$$C_6H_2O_2(NHPh)_2;\ C_6H_2O(NPh)(NHPh)_2.$$

18. Aromatic amines when boiled with *fatty amides* produce ammonia and alkyl-amides, *e.g.*

$$CH_3.CO.NH_2 + NPhH_2 = CH_3.CO.NPhH + NH_3.$$

19. *Silver salts* form additive compounds with amines (Mixter, *A. C. J.* 1, 239).

20. The *ferrocyanides* are obtained by adding the amines to a mixture of aqueous K_4FeCy_6 and hydrochloric acid; a crystalline pp. of the acid ferrocyanide $B'_2H_4FeCy_6xaq$, is usually formed (Fischer, *A.* 190, 184; Eisenberg, *A.* 205, 265). The ferrocyanides of tertiary amines are particularly insoluble in water and may be used as a means of isolating those amines. To recover the amine, the pp. is suspended in water and decomposed by $CuSO_4$, and the excess of $CuSO_4$ removed from the filtrate by baryta.

21. *Chloral hydrate* heated with tertiary aromatic amines and $ZnCl_2$ forms a condensation product which, when decomposed by aqueous KOH gives an aldehydo derivative, *e.g.*

$$CCl_3CH(OH)_2 + C_6H_5NMe_2 = CCl_3CH(OH).C_6H_4NMe_2 + H_2O$$

$$CCl_3CH(OH).C_6H_4NMe_2 = CCl_3H + HCO.C_6H_4NMe_2$$

(Boessneck, *B.* 18, 1516; 19, 365).

22. Primary aromatic amines in alcoholic solution absorb *cyanogen*; and the product when boiled with glacial HOAc becomes a di-alkyl-oxamide:

$$2PhNH_2 + C_2N_2 = PhNH.C(NH).C(NH).NPhH$$

$$PhNH.C(NH).C(NH).NPhH + 2H_2O = PhNH.CO.CO.NPhH + 2NH_3.$$

Aromatic *o*-diamines act similarly; the resulting oxalyl-*o*-diamine may be viewed as a di-oxy-quinoxaline (Bladin, *Bl.* [2] 42, 104).

23. Primary aromatic amines heated with *glycerin* (or acroleïn), H_2SO_4, and nitrobenzene (as oxidising agent) produce bases of the quinoline series. A similar reaction occurs when glycol (or paraldehyde) is substituted for glycerin.

24. *Nitric oxide* passed into an alcoholic solution of tertiary aromatic bases produces azo-compounds of the form $RR'N.C_6H_4.N_2.C_6H_4.NRR'$.

25. For the action of *aceto-acetic ether*, *v.* p. 19.

26. Orthodiamines form crystalline compounds with *glucose* (Griess a. Harrow, *B.* 20, 281).

27. *Diazobenzene chloride* reacts with primary and with secondary amines, forming diazo-amides (*v.* di-AZO-compounds). In the case of the secondary amines the compounds $C_6H_5.N_2.NRR'$, being easily crystallised and sl. sol. water, may be conveniently used in separation of these bases from tertiary and in some cases from primary bases (Wallach, *A.* 235, 235).

28. A solution of *potassium croconate* gives with salts of *o*-diamines dark-coloured pps. consisting of the corresponding azines (Nietzki, *B.* 19, 2727).

29. Tertiary aromatic amines form condensation products when heated with *aromatic acids or alcohols* in presence of $ZnCl_2$ or P_2O_5; water being eliminated at expense of H *para* to N (Fischer, *A.* 206, 85).

OTHER REACTIONS of the amines are described in articles on the several bases, *e.g.* METHYLAMINE, ETHYLAMINE, ANILINE, PHENYLENE-DIAMINE. See also **AMIDES**, **AMIDO ACIDS**, **AMIDINES**, and **AMIDOXIMS**.

AMISATIN *v.* ISATIN.

AMMELIDE $C_3H_4N_4O_2$ or $C_6H_8N_8O_4$ *i.e.* $C_3N_3(NH_2)(OH)_2$ (?). *Melanurenic acid.* '*Amido-cyanuric acid.*' *Mono-amide of cyanuric acid.* Liebig made a distinction between ammelide and melanurenic acid, but his ammelide was a mixture of ammeline and his melanurenic acid, hence it seems best to transfer the name ammelide to melanurenic acid (Klason, *J. pr.* [2] 33, 295).

Formation. — 1. From melam and conc. H_2SO_4 (Liebig, *A.* 10, 30; Gabriel, *B.* 8, 1165; Jager, *B.* 9, 1554).—2. From melam and boiling conc. KOHAq or conc. H_2SO_4 at 150° (K.).—3. From ammeline and conc. H_2SO_4 at 160° or by heating ammeline nitrate (Knapp, *A.* 21, 244); the change is incomplete.—4. A product of the dry distillation of urea (Liebig a. Wöhler, *A.* 54, 371; Laurent a. Gerhardt, *A. Ch.* [2] 19, 93; Drechsel, *J. pr.* [2] 11, 289).—5. Among products got by boiling mellon-potassium with aqueous KOH (Hennesberg, *A.* 73, 246; Liebig, *A.* 95, 269).—6. From its ethers or their thio-derivatives by gentle heat (K.).—7. From thio-ammelide and $KMnO_4$ (K.).—8. From cyanogen bromide and cyanamide at 100° (Cech a. Dehmel, *B.* 11, 25).—9. From urea and cyanogen iodide at 150° (Poensgen, *A.* 128, 339; Hallwachs, *A.* 153, 294; Schmidt, *J. pr.* [2] 5, 36).—10. In small quantity by action of $COCl_2$ on NH_3 (Bouchardat, *A.* 154, 355).—11. In small quantity from di-cyan-di-amide by heating with water at 160° or with aqueous ammonic carbonate at 120° (Bamberger, *B.* 16, 1078, 1703).

Preparation.—Conc. H_2SO_4 (300 g.) is slowly poured upon melam (100 g.) and the solution heated for a few minutes to 190°. When cold it is poured into a litre of water, when ammelide sulphate slowly crystallises (Striegler, *J. pr.* [2] 33, 163).

Properties.—White crystalline powder; v. sl. sol. water, insol. usual menstrua, sol. mineral acids, insol. acetic acid, v. sol. ammonia. It does not separate when its solution in warm aqueous NaOH is cooled (difference from ammeline). May be crystallised from boiling water. Not attacked by Cl, Br, HI, or AcCl.

Reactions.—1. Boiling dilute *acids* or *alkalis* form NH_3 and cyanuric acid. *Baryta-water* does not effect this change. — 2. *Phosphorus pentachloride* forms Cy_3Cl_3.—3. $KMnO_4$ in acid solution forms cyanuric acid.—4. *Water* at 170° forms CO_2 and NH_3.—5. Heated in a current of moist CO_2 it forms cyanamide.

Salts.—($H_2A'' = C_6H_8N_8O_4$).— $H_2A''H_2SO_43aq$.—$H_2A''2HNO_3$.—$H_2A''2HCl$.— $Na_2A''6aq$. — $NaHA''5aq$. — K_2A''. — KHA''. — $(NH_4)_2A''5aq$. — $(NH_4)HA''1\frac{1}{2}aq$. — $CaA''xaq$. — $BaA''2\frac{1}{2}aq$. — CuA''. — $NiA''2aq$. — Ag_2A''. — $AgHA''1\frac{1}{2}aq$ (Striegler; Volhard, *B.* 7, 92).

Di-methyl ether $C_5H_8N_4O_2$ *i.e.* $C_3N_3(NH_2)(OMe)_2$. [212°]. Formed by action of ammonia on trimethyl cyanurate, and occurs as a by-product in the preparation of that body (Hofmann a. Olshausen, *B.* 3, 273). Plates, sl. sol. cold alcohol, v. sl. sol. ether, sl. sol. cold water.—$C_5H_8N_4O_2AgNO_3$: needles.

Di-ethyl ether $C_7H_{12}N_4O_2$ *i.e.* $C_3N_3(NH_2)(OEt)_2$. [97°]. By-product in the action of CyCl on NaOEt, and formed by heating cyanetholin with aqueous NH_3 at 100° (H. a. O.). Prisms.—$C_7H_{12}N_4O_2AgNO_3$: needles. —$(C_7H_{12}N_4O_2)_2AgNO_3$: needles.

AMMELINE $C_3H_5N_5O$ *i.e.* $C_3N_3(NH_2)_2(OH)$. '*Di-amido-cyanuric acid.*' *Diamide of cyanuric acid.*

Formation.—1. By boiling melam for a long time with KOHAq or HClAq or by heating it with conc. H_2SO_4 at 100° (Liebig, *A.* 30, 24; Klason, *J. pr.* [2] 33, 286). — 2. From $Cy_3(NH_2)_2Cl$ by alkalis (Laurent a. Gerhardt, *A. Ch.* [3] 19, 92).—3. From thio-ammeline and $KMnO_4$.—4. From its ether or its thio derivative by HCl. — 5. Formed by boiling the hydrochloride of 'di-amido-tri-chloro-methyl cyanidine' (*v. Tri*-CHLORO-ACETONITRILE) with NH_3Aq:

$$Cy_3(NH_2)_2(CCl_3)HCl + NH_3 + H_2O = Cy_3(NH_2)_2(OH) + NH_4Cl + HCCl_3.$$

Also by heating tri-chloro-acetonitrile with NH_3Aq at 120°, or with alcoholic NH_3 at 170° (Weddige, *J. pr.* [2] 33, 85).

Properties. — Minute needles in dendritic groups (when ppd. from a warm solution). Insol. water, alcohol, ether, and benzene; sol. mineral acids; insol. acetic acid; sol. NH_3Aq. Separates when its solution in warm NaOHAq is cooled.

Reactions.—1. Split up by *heat* into NH_3 and mellon.—2. Warm H_2SO_4 forms NH_3 and ammelide.—3. Boiling dilute *nitric acid* forms first ammelide, then cyanuric acid (Knapp, *A.* 21, 255).

Salts.—Its compounds with acids are decomposed by water.—B'HCl: prisms.—$B'HNO_3$. —$B'AgNO_3$.

Ethyl ether $Cy_3(NH_2)_2OEt$. [190°-200°]. From cyanetholine and NH_3 (Hofmann a. Olshausen, *B.* 3, 275). V. sl. sol. alcohol.

Chloride $Cy_3(NH_2)_2Cl$. '*Chloro-cyanamide.*' From Cy_3Cl_3 and NH_3Aq (Liebig, *A.* 10, 43; Laurent a. Gerhardt, *A. Ch.* [2] 19, 90; 20, 98; Bineau, *A. Ch.* [2] 70, 254). Powder, insol. water. Decomposed by heating with HCl into mellon and NH_3. Dilute KOHAq converts it into ammeline. NH_3 at 100° forms melamine. KHS forms thio-ammeline.

AMMONIA NH_3. (*Volatile Alkali. Alkaline air.*) Mol. w. 17·01. [−75°. Faraday, *Q. J. S.* 19, 16]. (−38·5°; pressure less than 760 mm. Regnault.) S.G. $\frac{0°}{0}$ (liquid) ·6234 (Jolly, *A.* 117, 181: compare also Andreef, *ibid.* 110, 1). V.D. 8·5. S. 0°, 1050; 10°, 813; 15°, 727; 20°, 654; (Bunsen, *Gasometry*, Engl. ed. 169). S. 0°, 1148 (Roscoe a. Dittmar, *A.* 110, 140); S. 0°, 1270 (Berthelot, *C. R.* 76, 1041). C.E. (liquid −11° to 0°) ·00155 (Jolly, *A.* 117, 181). Refractive power (gas) compared with air = 1, 1·309. $[N, H^3] = 11,890$; $[N, H^3, Aq] = 20,320$; $[NH^3, Aq] = 8,430$ (*Th.* 2, 68).

Occurrence.—Ammonia salts occur in the atmosphere and in rain water; in many mineral waters; in sea water; near volcanoes; in many soils; in almost all plants; in the excrements of many animals; among the products of the decay of nitrogenous organic bodies. Free ammonia is not known to occur in nature. Ammonia was distinguished from ammonium carbonate by Black in 1756; Priestley obtained it approximately pure and named it *alkaline air*; Scheele showed it to contain nitrogen; Berthollet demonstrated its composition in 1785. The word ammonia comes from *sal ammoniacum*, the name given in the middle ages to ammonium chloride.

Formation.—1. By the action of the induction spark, or the silent discharge (Donkin, *Pr.* 21, 281), on a mixture of N and H in the ratio $N:H_3$ a small quantity of NH_3 is produced (Morren, *C. R.* 48, 432; Perrot, *C. R.* 49, 204; Chabrier, *C. R.* 75, 484).—2. According to Ramsay a. Young (*C. J.* 45, 93) a trace of NH_3 is formed when a mixture of moist N and H is passed through a red-hot tube containing iron filings; 3. Ammonium nitrite is formed, *a.* when hydrogen is burnt in air (Zöller a. Grete, *B.* 10, 2145; but against this *v.* Wright, *C. N.* 38, 240); *b.* by the action of a strong induction-spark on a mixture of N and H_2O (Thenard, *C. R.* 76, 983; Johnson, *C. N.* 48, 253 a. 264). Ammonium chloride is produced when electric sparks are passed for 8 to 10 hours through a mixture of HCl gas, N, and H, the elements being in the

ratio N:H_3 (Deville, *C. R.* 60, 817); or by passing the same gases through a red-hot porcelain tube containing a metal tube cooled by a stream of cold water (Deville, *A.* 135, 104).— 4. By the action of a porous body—*e.g.* spongy platinum, pumice, ferric oxide—aided by heat, on a mixture of H with an oxide of nitrogen or HNO_3, NH_3 is produced.—5. By decomposing a compound of H and one of N together, NH_3 is formed: *e.g.* by the action of water on nitride of Si, B, Mg &c., SiO_2, B_2O_3, or MgO is produced, and the N and H combine to form NH_3: again moist NO passed over hot iron filings yields NH_3. 6. By strongly heating easily oxidised bodies—*e.g.* As, Zn, K, &c.—with alkaline oxides, in presence of air.—7. By strongly heating metallic nitrates or nitrites with hydroxides of the alkali or alkaline earth metals and iron filings or zinc.—8. By heating metallic cyanides with steam (*v.* Marguerite and Sourdoval, *D. P. J.* 157, 73 and 316).—9. By heating solutions of nitrates or nitrites with KOHAq and Zn or Fe, or with a Cu-Zn couple. Ammonium sulphate is formed when nitric acid is dropped into a vessel containing Zn and dilute H_2SO_4Aq (Kuhlmann, *A.* 64, 233).—10. By the action of water on chloride, iodide, or phosphide, of nitrogen, or on the amides; in the last cases it is often necessary to use solutions of KOH or NaOH.—11. By the dry distillation of many nitrogenous organic bodies—*e.g.* horn, bones, blood, coal, &c. Ammonia is produced, according to Johnson, when N and H are passed over spongy Pt (*C. J.* 39, 128); but this is denied by Wright (*C. J.* 39, 359), whose experiments seem to prove that the NH_3 obtained by Johnson was the product of the mutual action of a trace of NO (in what was supposed to be pure N) and H, in presence of the spongy Pt (but *v.* also Johnson's pamphlet *Elementary Nitrogen, and on the Synthesis of Ammonia* [Churchill, 1885]).

Preparation.—1. By gently heating a mixture of 1 part chloride or sulphate of ammonium with 2 parts finally powdered slaked lime; the mixture is covered with a layer of lime to absorb water, and the gas is dried by passage through a cylinder containing lime in small pieces.—2. By gently heating a solution of $CaCl_2$ in NH_3Aq previously saturated with NH_3; this mixture may be kept unchanged for long.—3. Pure ammonia is prepared by Stas (*Fr.* 6, 423) by one of the following methods:—(i.) From pure NH_4Cl and KOHAq; 10 litres of a boiling conc. solution of NH_4Cl are mixed with 1 litre HNO_3Aq, S.G. 1·4; the boiling is continued so long as Cl comes off, the NH_4Cl which separates on cooling is dissolved in hot water, and again boiled with $\frac{1}{20}$ volume of HNO_3 till Cl ceases to come off, water is then added, and NH_3 is obtained by decomposing by KOHAq. (ii.) From pure $(NH_4)_2SO_4$ and KOHAq; 2 kilos. of $(NH_4)_2SO_4$ are heated with $1\frac{1}{2}$ kilos. conc. H_2SO_4 to the temperature whereat the sulphate begins to decompose with effervescence, small quantities of nitric acid are then added until the liquid becomes quite colourless; the salt which crystallises on cooling is dissolved in warm water and decomposed by KOHAq. [The object of these treatments is to remove the small quantities of substituted ammonias—**NH_2CH_3, $NH_2C_2H_5$ &c.—which are present in ammonium chloride and sulphate.] (iii.) From pure KNO_2 by the action of Zn and Fe in presence of KOHAq: the KNO_2 is prepared by heating 1 kilo KNO_3 with metallic copper, and** dissolving out the KNO_2 in water; this solution is digested with 15 litres KOHAq—S.G. 1·25—$3\frac{1}{2}$ kilos. granulated zinc free from carbon (Zn obtained by fusing commercial Zn with 5 p.c. PbO may be used), and $\frac{1}{2}$ kilo. iron wire previously strongly heated in air and then reduced by hydrogen; the liquid is poured off and distilled with gentle ebullition.

Properties.—A colourless, strongly-smelling, gas, which turns red litmus paper blue, and turmeric paper brown. Taste, hot and strongly alkaline; poisonous when breathed; it destroys the mucous membrane. Easily liquefied to a limpid, colourless, highly refractive, liquid; best by heating solid $2AgCl.3NH_3$ in one end of a strong glass tube, closed at both ends, and bent to an obtuse angle, the other end being surrounded by snow and salt (Faraday, *Q. J. S.* 19, 16). The silver compound begins to melt at 38°, it is quite liquid at 90°, begins to boil at 100°, and the change is complete at 112°. Liquefied at −40° to −50°; this may be effected by passing the well-dried gas through a U tube surrounded by a mixture of crystallised $CaCl_2$ and snow, or by liquid SO_2 which is rapidly evaporated by a current of air (Loir and Drion, *J.* 1860. 41). If liquid ammonia is cooled by solid CO_2 and ether *in vacuo* (Faraday), or by rapid evaporation over H_2SO_4 (Loir and Drion), white transparent crystals of solid ammonia are obtained, which melt at −75° (Faraday). Liquid ammonia vaporises in a closed vessel, the vapour-pressures according to Regnault (*J.* 1863. 66) being as follows:—

−30°	866·09	mm.	+40°	11,595·30	mm.
−20	1392·13	„	50	15,158·33	„
−10	2144·62	„	60	19,482·10	„
0	3183·34	„	70	24,675·55	„
+10	4575·03	„	80	30,843·09	„
20	6387·78	„	90	38,109·22	„
30	8700·97	„	100	46,608·24	„

Ammonia gas is very soluble in water (*v. Combinations* No. 1), alcohol, and ether; it is largely absorbed by charcoal (*v.* Hunter, *C. J.* [2] 9, 76; 10, 649) and other porous substances; it is absorbed by many saline solutions, the quantity of NH_3 absorbed being, as a rule, the less the more concentrated is the solution (*v.* Raoult, *C. R.* 77, 1078). Ammonia solution is a strongly smelling, caustic, alkaline, liquid; at −40° it forms long needle-shaped crystals; at −49° it solidifies to an inodorous mass; the B.P. and S.G. increase the less is the quantity of NH_3 present. Many metallic oxides insoluble in water are dissolved by NH_3Aq, *e.g.* CuO, Ag_2O, &c.; aqueous NH_3 also dissolves many fats and resins. Ammonia resembles PH_3 in its properties and reactions; it is, however, much more stable and less easily oxidised than that compound; an aqueous solution of NH_3, which doubtless contains NH_4OH, is characterised by the properties expressed by the word *alkali* (*v.* AMMONIUM COMPOUNDS; comp. also the arts. HYDRIDES, HYDROXIDES, and NITROGEN GROUP OF ELEMENTS.)

Reactions.—I. Liquid ammonia does not **react with H_2SO_4 at −65°; dissolves alkali metals**

at first with red, then blue, colour; the metals crystallise out unchanged (Gore, *Pr.* 21, 140); alkaline earth metals and heavy metals do not dissolve (Seeley, *C. N.* 23, 169; concerning solubilities of other elements and salts *v.* Gore *l.c.*).—II. Ammonia gas. 1. *Heat* decomposes NH_3 partially into N and H; when the gas is passed through an iron or porcelain tube, decomposition begins at about 500°; the nature of the hot surface exerts a most marked influence on the extent of decomposition; the decomposition is, however, never quite complete (Ramsay a. Young, *C. J.* 45, 88). A spiral of Pt heated by an electric current also decomposes NH_3 (Grove, *A.* 63, 1).—2. The *electric discharge* decomposes NH_3 slowly, but *induction sparks* from a large Ruhmkorff's coil more quickly; the decomposition is not quite complete (Deville, *A.* 135, 104; Buff a. Hofmann, *ibid.* 113, 132).—3. NH_3 is decomposed, into N and H, by passage over several *metals* at 700° or so, *e.g.* Au, Pt, Ag, Fe, Cu, &c.; some metals, *e.g.* Ti, combine with the N; the alkali metals set free $\frac{1}{3}$ of the H producing compounds of the form NH_2M: the compound NH_2K is decomposed at a red heat giving NK_3 and NH_3; water acts on it to produce KOH and NH_3 (*v.* Potassium).—4. Mixed with *oxygen and* submitted to the *electric discharge*, NH_4NO_2 and NH_4NO_3 are formed (Carius, *A.* 174, 31).—5. Mixed with *oxygen and heated*, NH_3 burns to H_2O, H, and N, if the NH_3 is in excess; and to H_2O, N, and NH_4NO_3, if the O is in excess (*v.* Hofmann, *A.* 115, 283; Heintz, *ibid.* 130, 102). The flame examined spectroscopically shows characteristic lines, especially one near D (Dibbits, *P.* 122, 521). 6. *Ozone* oxidises NH_3 chiefly to NH_4NO_3 and NH_4NO_2 (Carius, *A.* 174, 31).—7. A *platinum wire* heated in NH_3 mixed with air produces NH_4NO_2, if oxygen is passed into the NH_3 red fumes of N oxides are also produced.—8. Ammonia reacts with N_2O_3 and Cl_2O_3 to form H_2O, N, NH_4NO_2 or NH_4NO_3, and Cl.—9. *Metallic oxides* reducible by H are usually also reduced by NH_3 with formation of metal, N, and H_2O, sometimes with formation of metallic nitrides.—10. NH_3 reacts with many *metallic oxides and haloid salts* to form compounds, either of NH_3 with the metallic salt — *e.g.* $PtCl_2.4NH_3$, $CuSO_4.2NH_3$—or compounds in which part of the H of NH_3 is replaced, *e.g.* NH_2HgCl (*v.* Ammonium Compounds; also the several metals). 11. *Chlorine, bromine*, and *iodine* react energetically with NH_3 to produce NH_4X ($X = Cl$, Br, or I), and N. NH_3 combines with cooled I to form a brown liquid which is decomposed by water with production of NH_4IAq and explosive iodide of nitrogen [? NI_3] (*v.* Nitrogen).—12. *Sulphur* absorbs NH_3; on heating N is set free and ammonium sulphide formed (Brunner, *D.P.J.* 150, 371).—13. *Carbon* heated in a stream of NH_3 forms NH_4CN and H, sometimes also CH_4.—14. *Boron* heated in a stream of NH_3 form BN (*v.* Boron), and H.—15. NH_3 combines with *acids* (H_2SO_4, HCl, &c. &c.) to form ammonium salts ($(NH_4)_2SO_4$, NH_4Cl, &c. &c., *q.v.*; *v.* also *Combinations*, No. 4).—16. With many *organic anhydrides* NH_3 combines to form the ammonium salts of amic acids, *q.v.* NH_3 also **acts on several *inorganic anhydrides* and *acid chlorides* to form bodies more or less analogous to the amic acids; thus with $SO_2OH.Cl$ ammonia forms $NH(SO_2.ONH_4)_2$—the NH_4 salt of imido-sulphuric acid $NH(SO_2OH)_2$—from the salts of this acid are obtained salts of amido-sulphuric, or sulphamic, acid—$NH_2(SO_2OH)$. Again by the action of NH_3 on the acid chloride SO_2Cl_2 it is probable that the amide of sulphuric acid**—$(NH_2)_2SO_2$—is produced. So also NH_3 reacts with CO_2 to produce $NH_2(CO.ONH_4)$—the ammonium salt of amidocarbonic, or carbamic, acid. These compounds will be described under the various acids (*v.* Carbamic acid; Sulphamic acid; Sulphur oxyacids, nitrogen derivatives of; &c.).

III. Ammonia solution. 1. *Heat* decomposes NH_3Aq, the whole of the NH_3 being removed as gas.—2. *Chlorine, bromine*, and *iodine* react as with NH_3 gas; chlorine produces a little NH_4ClO_3 (Fresenius, *Fr.* 2, 59).—3. Reacts with *acids* to form ammonium salts (*v. Combinations*, No. 4, also Ammonium compounds).—4. With many *metallic salt solutions* it reacts (similarly to KOHAq) to form an ammonium salt and an oxide or hydroxide of the metal.—5. Heated with *sulphur* in a closed tube ammonium polysulphides are slowly formed (Flückiger, *J. Ph.* [3] 45, 453).—6. Heated with *selenion* in a closed tube, ammonium selenide and selenite are formed; with *tellurium* ammonium tellurite is produced (Flückiger, *l.c.*).

Combinations.—1. Ammonia gas dissolves very freely in *water*, the action is attended with production of heat; $[NH^3,Aq] = 8,130$ (*Th.* 2, 68); a concentrated solution of NH_3Aq diluted with n H_2O develops $\frac{1270}{n}$ units of heat (Berthelot, *A. Ch.* [5] 1, 209). Thomsen (*Th.* 3, 86) gives the following data

NH^3nH^2O,mH^2O

$n+m$	15	25	50
$n=3{\cdot}2$	319	350	372
„ 15	—	31	53
„ 25	—	—	22

The mass of NH_3 absorbed by water at 0° is not directly proportional to the pressure; for pressures varying from 50 to about 1,000 mm. the mass of NH_3 is less, and for higher pressures it is greater, than that calculated by Dalton and Henry's law (for data *v.* Roscoe a. Dittmar, *A.* 112, 349). As temperature increases the mass of NH_3 becomes more nearly directly proportional to the pressure, until at 100° the proportion is established (for data *v.* Sims, *A.* 118, 345). The S.G. of an aqueous solution of NH_3 varies from ·8844 at 14°, corresponding to 36 p.c. NH_3, to ·9991 (at 14°) corresponding to ·2 p.c. NH_3 (Carius, *A.* 99, 164). Carius gives the annexed table. Determinations made at 14° C.

A solution containing 32 p.c. NH_3 corresponds with the quantity calculated on the assumption that the liquid consists of the compound $NH_4OH.H_2O$ (*v.* Ammonium Compounds).—2. Dry *ammonium nitrate* absorbs NH_3 at all temperatures from −13° to +25° with liquefaction of the salt; heated over 25°, NH_3 is evolved and the substance becomes solid; the liquid at −10° and 760 mm. contains 42·5 grams NH_3 and 100 grams NH_4NO_3, these numbers agree with those calculated from the formula $NH_4NO_3.2NH_3$; **the solid at 28°·5 contains NH_4NO_3 and NH_3 in the proportion NH_4NO_3:NH_3 (Divers, *Pr.* 21, 109;**

Raoult, *C. R.* 76, 1261.—3. Ammonia gas combines with a great many *metallic chlorides*, *sulphates*, &c., to form either double compounds or compounds which are best regarded as substituted ammonium salts. (For a slight general sketch v. AMMONIUM COMPOUNDS. The several compounds are described in the arts. on the different metals).—4. Ammonia gas or solution combines with *acids* to form well-marked salts isomorphous with the corresponding salts of the alkali metals. The value of the heat of neutralisation of an acid by NH_3Aq is always rather smaller than the value when KOHAq or NaOHAq is used; thus Thomsen (*Th.* 1, 412-421) gives these numbers:

BAq	$[H^2SO^4Aq, BAq]$	$[H^2Cl^2Aq, BAq]$	$[H^2N^2O^6Aq, BAq]$
2KOHAq	31,288	27,504	27,544
2NaOHAq	31,578	27,488	27,364
$2NH_3Aq$	28,152	24,544	27,644

These results are quite in accordance with the view that an aqueous solution of NH_3 contains the compound $(NH_4)OH$, analogous in composition and properties to the hydroxides of the alkali metals (*v.* AMMONIUM COMPOUNDS).

Detection.—Free ammonia is detected: 1. by its smell; 2. by its action on HCl whereby white clouds of NH_4Cl are produced; 3. by its action on paper, *a.* moistened with neutral $HgNO_3Aq$, whereby a black stain (Hg_2O) is formed, *b.* moistened with $CuSO_4Aq$ whereby a sky-blue colour ($CuSO_4.4NH_3$) is produced, *c.* moistened with $MnSO_4Aq$, whereby brown spots (Mn_2O_3) are formed, *d.* steeped in an ethereal solution of alkanna root (Enz, *J.* 1870. 935), whereby a blue colour is produced (Böttger, *J. pr.* 107, 146). The presence of ammonia or ammonium salts can be ascertained by various tests; the following may be mentioned.—4. *Sodium picrate* precipitates yellow ammonium picrate.—5. A solution of *sodium molybdate* containing phosphoric and nitric acids forms a citron yellow pp. (Sonnenschein, *J. pr.* 56, 302).—6. *Nessler's solution*—a strongly alkaline solution of HgI_2 in KIAq—forms a brown pp., or brown colour in *extremely dilute* solution, of $NHg_2I.H_2O$ (Nessler, *C. C.* 1856. 529). All ammonium salts are at least partly volatilised when heated; some give sublimates of the original salt, *e.g.* NH_4Cl; others are decomposed, *e.g.* NH_4NO_3 and NH_4NO_2.

Estimation.—1. Ammonium salts are sometimes estimated in a mixture, all the other constituents of which are non-volatile, by heating a specified quantity and determining the loss of weight.—2. All ammonium salts are decomposed by heating with KOHAq (or NaOHAq) with evolution of NH_3: if organic N-containing compounds which evolve NH_3 by the action of alkalis are absent, it is only necessary to add a weighed quantity of the ammonium compound to an excess of KOHAq, or NaOHAq, which has been boiled and cooled, in a flask connected with a condenser and receiver, and to warm on a sand-bath; NH_3 passes over and is received in dilute HClAq; the NH_4Cl is then transformed into $2NH_4Cl.PtCl_4$ (*v.* No. 3), or the NH_3 is received in a measured quantity—excess—of standardised HClAq, H_2SO_4Aq, or $H_2C_2O_4Aq$, and the residual acid is determined by titration with standard alkali. [A special apparatus is described by Harcourt (*Fr.* 2, 14).] If N-containing organic compounds are present which evolve NH_3 by the action of alkalis, Schlossing

(*A. Ch.* [3] 31, 153) recommends to place the substance with excess of milk of lime over a measured quantity of standard H_2SO_4Aq, under a bell jar, for 48 hours, and then to determine the residual acid by standard alkali.—3. Ammonium salts the acids of which are soluble in alcohol may be estimated by conversion into $2NH_4Cl.PtCl_4$; an excess of nearly neutral $PtCl_4Aq$, free from HNO_3, is added to the solution, the liquid is evaporated at 100°, the residue is washed with alcohol, dried at 100°, and weighed, or it is strongly heated and the residual platinum is weighed. This method is applicable in the presence of salts which form double compounds with Pt soluble in alcohol; it is best that such salts should be chlorides, to insure this the mixture is evaporated with excess of conc. HClAq (it is best to remove sulphuric acid by $Ba(OH)_2$, excess of $Ba(OH)_2$ being afterwards removed by CO_2). In the case of KCl, which forms a salt $2KCl.PtCl_4$ insoluble in alcohol, the mixed Pt salts are weighed, then strongly heated and again weighed, the KCl is dissolved out in water, and the residual Pt is weighed.—4. Ammonium salts are decomposed by alkaline hypochlorites or hypobromites giving off all their N, which may be collected and measured.

$$(2NH_4ClAq + 3NaClOAq = N_2 + 3NaClAq + 3H_2O + 2HClAq).$$

Wöhler employed calcium hypochlorite for the purpose; Knop (*Fr.* 9, 225) used barium or sodium hypobromite (prepared by the action of Br on $Ba(OH)_2Aq$ or on NaOHAq); Schiff has described a special apparatus (*Fr.* 7, 430); Krocker a. Dietrich (*Fr.* 3, 64; 5, 40) decompose by excess of brominated NaOClAq, and determine the residual hypochlorite by titrating with an alkaline solution of arsenious oxide. (Comp. also Foster, *C. J.* 33, 470.)—5. Minute quantities of NH_3 are determined by the colorimetric process of Nesslerising; a measured quantity of Nessler's reagent —HgI_2 in KIAq made strongly alkaline by KOHAq—is added, and the colour is compared with that produced by an equal quantity of Nessler's solution in an equal volume of water containing a known quantity of ammonia.

M. M. P. M.

AMMONIA, ACTION ON ORGANIC BODIES. **1.** Ammonia converts alkyl salts of inorganic acids into amines (*q. v.*).—2. It converts alkyl salts of carboxylic acids into amides (*q. v.*).—3. It converts the oxides of acid radicles into amide and ammonium salt: $Ac_2O + 2NH_3 = AcNH_2 + AcONH_4$.—4. It converts chlorides of acid radicles into amides of the corresponding acids: $AcCl + 2NH_3 = AcNH_2 + NH_4Cl$.—5. It unites with cyanic ethers forming ureas.—6. It unites with thio-carbimides forming thioureas.—7. It unites with aldehydes, but in the case of the higher fatty aldehydes and the aromatic aldehydes water is simultaneously split off.—8. It unites with ketones and quinones.—9. Alcoholic NH_3 sometimes removes HCl; thus, it converts isobutylidene chloride $Me_2CH.CHCl_2$, chloro-iso-butylene $Me_2C:CHCl$, and di-chloropropane $CH_3.CCl_2.CH_3$, into chloro-propylene $CH_3CCl:CH_2$ (Oeconomides, *C. R.* 92, 1235).—10. For its action on oxy compounds see AMINES, *Formation* 10.—11. Ammonia can displace O by NH.

AMMONIAC GUM *v.* GUM.

AMMONIUM COMPOUNDS. Compounds produced by the action of ammonia on acids. The conditions of occurrence in nature, and also of the artificial syntheses, of these salts are referred to in the article AMMONIA, *q. v.* In that article some data are given regarding the absorption of ammonia by water (*Combinations*, No. 1), and regarding the thermal values of the neutralisation of acids by NH_3Aq (*Combinations*, No. 4). The products of the mutual actions of NH_3Aq, and HClAq, H_2SO_4Aq, and other acids—the ammonium salts—are for the most part white crystalline bodies, easily soluble in water, and many of them soluble also in alcohol; they exhibit marked analogies with the salts of potassium. Corresponding ammonium and potassium salts are isomorphous, hence they probably have similar compositions. The ammonium salts are distinguished by their comparatively great volatility; heated, as solids, they are completely volatilised, if the acid of the salt is volatile; if the acid is non-volatile (*e.g.* borate or phosphate), ammonia is evolved. They do not exist as gases; when volatilised they are either decomposed *e.g.* NH_4NO_3, or dissociated *e.g.* NH_4Cl, *q. v.* (*v.* also DISSOCIATION). When gaseous NH_3 acts on gaseous HCl, HBr, or HI, combination occurs with production of much heat and formation of solid compounds NH_3HX, thus (*Th.* 2, 75):

X	(NH^3, HX)
Cl	41,900
Br	45,020
I	43,460

If the solid products of these actions, NH_3HX, are heated to about 450°, a vapour is obtained containing NH_3 and HX; on cooling this vapour the compound NH_3HX is re-formed. Gaseous NH_3 does not combine with HCl, HBr, or HI, at temperatures above about 450°. These facts establish a difference between the ammonium and potassium compounds. This difference is further exhibited in the reactions of the two classes of compounds; the ammonium salts are easily decomposed, *e.g.* by alkalis and alkaline earths, with production of NH_3. On the other hand the properties of NH_3Aq (*v.* AMMONIA, *Properties of*) are so similar to those of KOHAq, and the reactions of acids with these solutions, whether considered thermally or chemically, are so analogous, that there can be little doubt that the composition of ammonium salts is similar to that of potassium salts. This similarity is at once rendered apparent by formulating the former class of salts as compounds of the hypothetical group of atoms NH_4, *ammonium*. Thus we have:

$NH_4.Cl$ isomorphous with and chemically analogous to $K.Cl$,
$NH_4.NO_3$ isomorphous with and chemically analogous to $K.NO_3$,
$(NH_4)_2.SO_4$ isomorphous with and chemically analogous to $K_2.SO_4$,
$(NH_4)_2.C_2O_4$ isomorphous with and chemically analogous to $K_2.C_2O_4$,
$NH_4.C_2H_3O_2$ isomorphous with and chemically analogous to $K.C_2H_3O_2$.

If this analogy of properties is in all cases supposed to accompany analogy of composition, then NH_3Aq must be formulated as $NH_4.OHAq$. The compound NH_4OH has not been separated from the solution of NH_3 in water; but this does not prove the non-existence of the compound in this solution. A chemical compound may, and sometimes almost certainly does, exist as a member of a system, and yet it may be incapable of existence apart from the other members of the system. The existence of every compound is conditioned by other factors than the elements which compose it; among these factors, temperature, and the presence or absence of other compounds, are very important. Compounds closely resembling NH_4OH, and undoubtedly derived from NH_4OH, are known as definite solid bodies; they are obtained by replacing the four hydrogen atoms in the complex NH_4OH by alcoholic radicles C_nH_{2n+1} or C_nH_{2n-7}; thus $N(CH_3)_4.OH$, $N(C_2H_5)_4.OH$, and $N[(C_2H_5)_2(C_6H_5)_2]OH$, have been prepared. These bodies closely resemble NaOH and KOH in their properties; their existence and properties are strong arguments in favour of the existence of the compound NH_4OH in aqueous solutions of NH_3. The formulæ $NH_4.OH$, $NH_4.Cl$, $(NH_4)_2SO_4$ &c., then better summarise the properties and reactions, and suggest the analogies, of the ammonium compounds, than the alternative formulæ $NH_3.H_2O$, $NH_3.HCl$, $(NH_3)_2.H_2SO_4$ &c. The name *ammonium* is given to the compound radicle, or group of atoms, NH_4. We do not know that the composition of the molecule of ammonium chloride is represented by the formula NH_4Cl; indeed we do not even know the molecular weight of this, or of any other, ammonium compound. These compounds seem to exist only as solids, or in solution. We are scarcely justified in applying the term molecule to the chemically reacting small particles of solids or liquids, unless the term is used in a wider and vaguer sense than is given to it when we speak of the molecule of a gas (*v.* ATOMIC AND MOLECULAR WEIGHTS). But in saying that the complex or collocation of atoms which forms the reacting weight of ammonium chloride is a combination of an atom of chlorine with the radicle, or group of atoms, ammonium, we mean to imply that, when this complex of atoms reacts with various other kinds of matter, it behaves as if the four atoms of hydrogen were, in some way, more directly and closely related to the atom of nitrogen than to the atom of chlorine. The fact that when the same complex of atoms is heated it separates into two distinct molecules, HCl and NH_3, neither proves nor disproves the correctness of the formula $NH_4.Cl$, and the conception which that formula embodies. Neither does the fact, that no gaseous molecule is known containing a single atom of nitrogen combined with more than three monovalent atoms, disprove the formula $NH_4.Cl$; for the solid compound ammonium chloride presents us with phenomena to which the conceptions regarding the valencies of atoms, which have been gained by the study of gaseous molecules, are not strictly applicable.

In connection with the constitution of ammonium compounds it is of interest to observe that the compound produced by the union of $N(CH_3)_2C_2H_5$ with C_2H_5I appears to be identical with the compound produced by the union of $N(C_2H_5)_2CH_3$ with CH_3I; it seems as if this compound $N[(CH_3)_2(C_2H_5)_2]I$ belonged to the same form or type as $NH_4.I$, $NH_4.Cl$, $NH_4.OH$, &c. (V. Meyer and Lecco, *B.* 8, 233 a. 936).

The group of atoms, NH_4, is evidently chemically comparable with the atoms K, Na, Li, Cs, or Rb; but these are the atoms of strongly positive metals; hence if the group NH_4 could be isolated it might be expected to exhibit properties similar to those of the alkali metals. Experiments have demonstrated the impossibility of the existence of NH_4 uncombined with other atoms; but certain reactions are known which suggest the existence of an alloy of this hypothetical metallic radicle with mercury.

AMMONIUM AMALGAM. If an electric current is passed through conc. NH_3Aq, or NH_4ClAq, the negative electrode consisting of mercury and the positive of a platinum wire, the mercury swells up, sometimes to 20 times its original volume, and becomes pasty so that it may be lifted by the hand, while nitrogen is evolved at the positive electrode. The same result is obtained as regards the mercury, if a piece of solid NH_4Cl is used; also if sodium-amalgam, containing about 1 p.c. Na, is placed in conc. NH_4ClAq—in this case NaClAq is produced. The peculiar, pasty, lustrous, metal-like, substance formed in these experiments is called ammonium-amalgam; at a very low temperature, obtained by solid CO_2 and ether, it is a dark-grey, solid, crystalline, mass; even at −29° it begins to evolve NH_3 and H, and this change proceeds rapidly at moderate temperatures; the two gases always come off in the ratio NH_3 : H.

An amalgam of K with Hg is produced by electrolysis under conditions very similar to those which attend the production of ammonium-amalgam; the analogy between ammonium and potassium is thus carried out here also. Ammonium-amalgam, it is said, does not reduce salts of Ag, Cu, or Fe, as K amalgam does (Landolt, *A. Suppl.* 6, 346). When the amalgam is subjected to increased pressure its volume is found to change almost inversely as the pressure; in this respect then it behaves like a gas rather than a semi-solid compound. The following data are given by Routledge (*C. N.* 26, 210):—

c.c. of Hg in amalgam.	c.c. of amalgam, pressure 762 mm.	Increased pressure applied, in mm. of Hg.	c.c. of amalgam under increased pressure.	c.c. of amalgam calculated by Boyle's law.
14·5	21·0	1524	18·0	17·9
24·4	36·2	1524	31·6	30·9
10·4	18·0	1863	14·7	13·7
23·8	42·2	1026	38·8	38·5
23·8	42·0	2015	32·2	31·6
23·8	36·2	1495	32·6	30·6
29·2	39·5	1989	34·4	35·4

As the pressure increases, the surface of the amalgam becomes brighter, until under large pressures it has the appearance and liquidity of mercury (Seeley, *C. N.* 21, 265). These results point to the existence of gaseous NH_3 or H, or, it may be, gaseous NH_4, in the Hg; but they do not disprove the existence of the atomic group NH_4 in some kind of loose combination with Hg. An alloy of Fe and NH_4

is said by Meidinger (*C. C.* 1862. 78) to be formed when $FeSO_4Aq$ or $FeCl_2Aq$, to which a considerable quantity of NH_4ClAq has been added, is electrolysed by a strong current, the negative electrode consisting of a copper wire.

By electrolysing aqueous solutions of ammonium salts using carbon electrodes, Bartoli a. Papasogli (*G.* 13, 281) obtained benzenecarboxylic acids and a compound of C, H, O, and N, resembling mellogen.

Of the ammonium compounds we have here to consider the *bromide*, *chloride*, *fluorides*, *iodides*, *selenides*, *telluride*, and *sulphides*; the others will be considered under the headings CARBONATES, NITRATES, SULPHATES, &c. The hydroxide, known only in aqueous solution, has been already treated of in the art. AMMONIA.

Ammonium bromide. NH_4Br. Mol. w. unknown; does not exist as a gas, but is dissociated by heat into $HBr + NH_3$. S.G. $\frac{4^\circ}{}$ 2·379 (Schröder, *P.* 106, 242). S. G. $\frac{15^\circ}{4}$ 2·327 (Eder, *Sitz. W.* 82 (2), 1284). V. D. at 440° to 860° 24·4 (Deville and Troost, *C. R.* 49, 239; 56, 881). S. (10°) 66·2; (16°) 72; (30°) 81·1; (50°) 94·1; (100°) 128·2. S. (alcohol, S.G. ·806, 15°) 3·1; (75°) 10·5. S. (ether S. G. ·729) ·12 (Eder, *l.c.*). $[NH^3, HBr] = 45{,}020$; $[N, H^4, Br] = 65{,}348$ (*Th.* 2, 75). $[NH^4Br, Aq] = -4380$ (*Th.* 3, 197). S.V.S. 41·7.

Formation.—1. By adding HBr or HBrAq to NH_3 or NH_3Aq. 2. By the action of Br on NH_3Aq; $4NH_3Aq + 3Br = 3NH_4BrAq + N$: on evaporation, crystals are obtained.

Properties and Reactions.—White crystals; soluble in water; the act of solution is attended with absorption of much heat. Exposed to moist air turns yellow, and acquires an acid reaction. An aqueous solution gives off ammonia at moderately low temperatures.

Troost (*C. R.* 92, 715) describes three compounds, $NH_4Br.xNH_3$, $x = 1, 3$, and 6, obtained by the action of excess of NH_3 on warm NH_4Br; the dissociation-phenomena of these compounds have been studied by Roozeboom (*R.T.C.* 4, 361).

Ammonium chloride. NH_4Cl. (*Sal ammoniac.*) Mol. w. unknown; does not exist as gas, but is dissociated by heat into $NH_3 + HCl$. S.G. 1·52 (Schröder, *P.* 106, 242). V.D. at 350° = 14·4, at 1040° = 14·5 (Deville a. Troost, *C. R.* 49, 239; 56, 891); but vapour consists of equal volumes of NH_3 and HCl (*v. Reactions*, No. 1). S.H. (15° to 45°) ·373 (Kopp, *T.* 155, 71). S.H. (23° to 100°) ·3908 (Neumann, *P.* 126, 123). C.E. (cubical, 0° to 40°) ·00018764 (Fizeau, *C. R.* 64, 814). S.V.S. 35·2. S. (0°) 28·4; (10°) 32·8; (110°) 77·2; S. increases approximately 4·4 parts for each 10° (Alluard, *C. R.* 59, 500). S. (alcohol S.G. ·939, 8°) 12·6; (56°) 30·1 (Gerardin, *A. Ch.* [4] 5, 129). $[NH^3, HCl] = 41{,}900$; $[NH^3Aq, HClAq] = 12{,}270$; $[N, H^4, Cl] = 75{,}790$ (*Th.* 2, 75). $[NH^4Cl, Aq] = -3{,}880$ (*Th.* 3, 197).

$[NH^4Cl.nH^2O, mH^2O]$ (*Th.* 3, 109).

Occurrence.—In small quantities, in the neighbourhood of volcanoes, and in fumaroles; in some animal secretions, *e.g.* saliva.

Formation.—1. By mixing HCl and NH_3 in equal volumes. 2. By the action of HCl on N and H, under the influence of the electric discharge, or when heated and quickly cooled (for details *v.* AMMONIA, *Formation*, Nos. 1, 2, and 3).—3. By the decay, or destructive distillation, of various N-containing organic matters.

The name *Sal ammoniacum* seems to have been given by the earlier chemists to rock-salt; Geber, probably latter part of 8th century, prepared ammonium chloride from urine and common salt; towards the end of the seventeenth century the name *Sal ammoniacum* came to be applied to ammonium chloride. The salt was prepared in Egypt by sublimation from the sooty deposit obtained by burning camel's dung. The first manufactory of sal ammoniac in this country was established at Edinburgh in 1756.

Preparation.—Crude ammonium carbonate obtained by the dry distillation of bones, horn, blood, &c., or gas coal, is decomposed by hot milk of lime, and the NH_3 produced is led into HClAq, the liquid is boiled down, and the crude NH_4Cl is purified by solution, filtration through animal charcoal, re-crystallisation, and sublimation. For details of preparation of pure NH_4Cl *v.* AMMONIA, *Preparation No.* 3.

Properties.—Pure ammonium chloride is a white, inodorous, salt, with a pungent taste; it crystallises from aqueous solutions in small cubes or octahedra which gather together into feathery masses (*v.* further, Naumann, *J. pr.* 50, 11 and 310). By sublimation and rapid cooling it is obtained as a loosely cohering powder consisting of minute octahedra; the ordinary sublimed salt has been partially fused and appears as a semi-translucent mass of fibrous crystals. It is very tough, and cannot be powdered; sal ammoniac is best obtained in fine powder by evaporating a solution to dryness with constant stirring. It is easily soluble in water (*v.* data at beginning of article); a conc. aqueous solution boils at 115·8° at 768 mm. (Alluard, *C. R.* 59, 500); S.G. $\frac{15^\circ}{}$ of conc. NH_4ClAq containing 26 p.c. NH_4Cl is 1·0752 (Michel a. Krafft, *A. Ch.* [3] 41, 471). Tables of S.G. of NH_4ClAq are given by Gerlach (*J.* 1859. 42), and Schiff (*A.* 110, 74). On heating NH_4ClAq of 10·6 p.c. to 37° NH_3 is given off in the water-vapour (Leeds, *Am. S.* [3] 7, 197); as temperature increases the decomposition of NH_4Cl probably increases also (*v.* Fittig, *A.* 128, 189; Dibbits, *B.* 5, 820; Brücke, *J. pr.* 104, 481).

Reactions.—1. When NH_4Cl is *heated* it vaporises, but the vapour is found to consist of HCl and NH_3 (*v.* Pebal, *A.* 123, 199; Than, *A.* 131, 129; Wanklyn, *P.M.* [4], 29, 112; Wurtz, *J.* 1859. 30; Deville a. Troost, *C. R.* 49, 239; 56, 891; Tommasi, *B.* 14, 353). The density of the vapour is 12·9 according to Bineau (*A. Ch.* [2] 68, 416); 14·4 at 350°, and the same at 1010°, according to Deville and Troost (*C. R.* 49, 239; 56, 891). Than (*l.c.*) has shown that HCl does not combine with NH_3 at 350° or higher temperatures.—2. NH_4ClAq is decomposed by *chlorine* with formation of HCl and nitrogen chloride (*q. v.*).—3. Heated with *iron*, *zinc*, or better with *potassium*, NH_4Cl is decomposed with production of metallic chloride, NH_3, and H; in presence of air and moisture the reaction proceeds rapidly with formation of metallic chloride or oxychloride and NH_3.—4. Many *metallic oxides* decompose NH_4Cl with formation of chlorides, and NH_3; in some cases—*e.g.* oxides of Hg, Pt, Au &c.—the chloride combines with a portion of the NH_4Cl to form a double compound. 5. *Alkaline carbonates* decompose NH_4Cl when heated with volatilisation of ammonium carbonate. *Calcium carbonate*, especially when freshly precipitated, dissolves readily in NH_4ClAq; on heating, ammonium carbonate is evolved.—6. *Crystallised sodium sulphate* partially decomposes NH_4Cl when the two are mixed together by rubbing, NaCl and $(NH_4)_2SO_4$ being formed and partly dissolving in the water which comes from the sodium sulphate crystals.—7. *Sulphuric anhydride* vapour is absorbed by powdered NH_4Cl, on warming HCl is evolved and $SO_2NH_2ONH_4$ is formed; if water is added $(NH_4)_2SO_4$ is produced.—8. The reaction between *acids* and NH_4Cl follows the ordinary course of the interaction of acids with salts of other acids.

Combinations. — 1. NH_4Cl combines with many *metallic chlorides* to form double compounds; *e.g.* $PtCl_4.2NH_4Cl$; $HgCl_2.2NH_4Cl$; $CuCl_2.2NH_4Cl$ &c. (*v.* the several METALS).—2. With an aqueous solution of ICl_3, the compound $NH_4Cl.ICl_3$ is produced (*v.* AMMONIUM IODIDE; *Reactions*, No. 2).—3. According to Troost (*C. R.* 88, 578) when NH_4Cl is heated with a large excess of pure dry *ammonia*, at least two compounds are formed: $HCl.4NH_3$, melting at 7°; and $HCl.7NH_3$, formed at $-31°$ and 750 mm., melting at $-18°$.

Ammonium fluorides (Marignac, *Ann. M.* [5] 15, 221).

I. NEUTRAL SALT. NH_4F. Mol. w. unknown. $[NH^3Aq, HFAq] = 15,200$ $[NH^3, HF] = 30,100$ (Guntz, *C. R.* 97, 1483). *Formation.*—1. By mixing HF and NH_3.—2. By heating KF or NaF with NH_4Cl. *Preparation.*—1. By gently heating a *dry* finely powdered mixture of 1 part NH_4Cl with $3\frac{1}{4}$ parts KF in a platinum crucible covered with a lid, which is kept cold by dropping water on to it; the NH_4F sublimes on to the lid.—2. Ordinary HFAq is saturated with NH_3Aq, a little $(NH_4)_2CO_3Aq$ is added, the clear liquid is decanted and evaporated in a platinum dish with repeated additions of small pieces of solid ammonium carbonate. *Properties.*—Hexagonal prisms with strong saline taste; unchanged in dry air, but deliquescent in moist air; easily soluble in water, less soluble in alcohol; an aqueous solution gives off NH_3 and acquires an acid reaction; the dry salt absorbs NH_3 but gives it off again on heating; sublimes readily with previous fusion; etches glass, and must be kept in platinum, silver, or gutta percha, vessels. *Reactions.*—1. When moist, or in solution in water, NH_4F decomposes *silicates* with formation of SiF_4; the same decomposition is effected by the dry salt by heating it with silicates.—2. An aqueous solution is decomposed by *heat*, with formation of the acid salt $NH_4F.HF$ and evolution of NH_3 (*v. infra*).

II. ACID SALT. $NH_4F.HF$. Mol. w. unknown. S.G. 1·21. *Formation.*—1. By evaporating an aqueous solution of NH_4F at 36° to 40° in a platinum dish.—2. By adding excess of NH_3Aq to a solution of fluosilicic acid, and evaporating; as thus obtained the salt is mixed with silica. *Properties.*—Colourless prisms; easily soluble in water; slightly deliquescent; easily volatilised, vapour being very acrid.

Ammonium iodides.

I. NH_4I. Mol. w. unknown; does not exist as gas, but is dissociated by heat into $NH_3 + HI$. S.G.$^{11°}$ 2·498. S.V.S. 58. V.D. (440° to 860°) 38·8, but vapour consists of equal volumes of HI and NH_3. $[NH^3, HI] = 43,462$; $[N,H^4,I] = 49,313$ (*Th.* 2, 75). $[NH^4I,Aq] = -3,550$ (*Th.* 3, 197). *Formation.*—1. By mixing equal volumes of HI and NH_3, or by acting on HIAq with NH_3Aq.—2. By decomposing Fe_2I_6Aq by $(NH_4)_2CO_3Aq$, or BaI_2Aq by $(NH_4)_2SO_4Aq$. *Preparation.*—1. Hot saturated solutions of $(NH_4)_2SO_4$ and KI, equal equivalents, are mixed; after cooling, alcohol equal to 15 p.c. of the water used is added; the liquid is filtered after 12 hours, and evaporated with addition of a little NH_3Aq from time to time (Jacobsen, *C. C.* 1864. 192).—2. A solution of $27\frac{1}{2}$ parts KI in 48 parts H_2O is mixed with a solution of 22 parts tartaric acid in 48 parts water, the mixture is placed in a freezing mixture to separate $KHC_4H_4O_6$, the filtrate is evaporated at 100° with addition of a little $(NH_4)_2CO_3$ (Beyer, *D. P. J.* 171, 467). *Properties.*—Colourless cakes, very soluble in water and alcohol; deliquesces in moist air, and becomes yellow through separation of I, and loss of NH_3; may be sublimed unchanged in absence of air. *Reactions.*—1. NH_4IAq is easily decomposed by dilute *acids*; the solid compound is decomposed by dry HCl gas at high temperatures, at 360° about $\frac{1}{20}$th, at 440° about $\frac{1}{6}$th, at a dark red heat about $\frac{4}{9}$ths, of the NH_4I being decomposed (Hautefeuille, *C. R.* 64, 704).—2. *Chlorine* led into saturated NH_4IAq produces long, golden-yellow, needles of $NH_4Cl.ICl_3$ (Filhol, *J. Ph.* 25, 441); this compound is decomposed by gentle heating into ICl_3 and NH_4Cl.—3. By heating in *ammonia*, the compounds $NH_4I.xNH_3$ $x = 1, 3$, and 6, are obtained according to Troost (*C. R.* 92, 715).

II. According to Guthrie (*C. J.* [2] 1, 239) a compound of NH_4I with I—$NH_4I.I$—is obtained, as a brownish-black liquid, soluble in alcohol, ether, CS_2, and KIAq, less soluble in $CHCl_3$, when I is added in small quantities to a conc. solution of NH_4NO_3 with which $\frac{1}{3}$ equivalent of KOH has been mixed. $NH_4I.I$ easily separates in dry air into NH_3 and I; water or dilute alkali produces iodide of nitrogen, NH_4I, and HI; mercury acts on it to form HgI_2 and NH_3; aqueous solutions of acids produce NH_4 salts and separate I.

Johnson (*C. J.* 33, 397) describes a compound of NH_4I and I the composition of which agrees with the formula NH_4I_3. It is produced by adding I to NH_4I in presence of a little water until no more I dissolves. It forms dark-blue, somewhat deliquescent, prisms; S.G. 3·749; soluble in a little water, decomposed on dilution with precipitation of I. This compound seems to form a double salt with KI, viz. $5NH_4I_3.KI$, obtained by passing NH_3 into the mother liquor from which KI_3 has separated.

Ammonium selenides $(NH_4)_2Se$, and $(NH_4)SeH$ (Bineau, *A. Ch.* [2] 67, 229). Neither has been gasified and therefore *mol. ws.* are unknown. NH_3 has no action on Se, but readily combines with H_2Se; when excess of NH_3 is used 2 vols. combine with 1 vol. H_2Se and produce $(NH_4)_2Se$, when excess of H_2Se is used equal vols. of the gases combine and form $NH_4.HSe$. These compounds are white solids which soon turn red by exposure to air or when dissolved in air-containing water; both smell of NH_3 and H_2Se and appear easily to undergo change; their aqueous solutions probably contain polyselenides although none of these has been isolated; the products of the distillation of K_2Se with NH_4Cl probably also contain ammonium polyselenides.

Ammonium telluride $NH_4.HTe$. White leaf-shaped crystals; easily soluble in water, volatilised at 80°. Formed by the direct union of NH_3 and H_2Te (Bineau, *A. Ch.* [2] 67, 229).

Ammonium sulphides, and Sulphydrate or Hydrosulphide. Five solid sulphides, and a hydrosulphide, of ammonium are known; their compositions are expressed by the formulæ NH_4HS, $(NH_4)_2S$, $(NH_4)_2S_2$, $(NH_4)_2S_4$, $(NH_4)_2S_5$, $(NH_4)_2S_7$; none of these exists in the gaseous state; the first and second, which have been more studied than the others, are dissociated by heat, into $NH_3 + H_2S$, and $2NH_3 + H_2S$, respectively. All the ammonium sulphides are soluble in water, they very easily undergo change at ordinary temperatures, usually giving off NH_3, and H_2S which is often partly decomposed with precipitation of S. They are all decomposed by dilute acids with precipitation of white amorphous S, evolution of H_2S, and formation of an ammonium salt of the reacting acid. These sulphides act as salt-forming or basic compounds towards such acidic sulphides as As_2S_3, As_2S_5, Sb_2S_3 &c. (*v. infra*: also ARSENIC, and ANTIMONY, THIO-ACIDS). According to Berzelius any one of the ammonium sulphides, except $(NH_4)_2S_7$, can be prepared by gently heating the corresponding sulphide of potassium with sal ammoniac; in every case except that of K_2S_5 the NH_4Cl must be in excess, else part of the ammonium sulphide formed is decomposed with production of S (NH_3 and H) which combines with the potassium sulphide to form K_2S_5. Little or nothing is known of the physical constants of these compounds; the following thermal data are given, but, by reason of the instability of the sulphides and the indirect methods by which the numbers have been obtained, they must be accepted with caution:—

H.F. of solids from gaseous N and H, and solid S.

$$\left.\begin{array}{l}(NH_4)_2\,S_2 = 69{,}000\\ (NH_4)_2\,S_4 = 69{,}600\end{array}\right\}\text{(Sabatier, } C.\ R.\text{ 91, 53)}$$

$$(NH_4)_2\,S_5 = 69{,}400 \quad \text{(Sabatier, } A.\ Ch.\text{ [5] 22, 73).}$$

The tetra- and penta-sulphide dissolve in water with absorption of about 8,000 gram-units of heat per formula-weight of the sulphide.

The sulphides of ammonium have been studied chiefly by Fritzsche (*J. pr.* 24, 460; 32, 313).

Preparation.—NH_4HS is prepared by the reaction of equal volumes of NH_3 and H_2S at the ordinary temperature, or at temperatures not lower than −10°. An aqueous solution of NH_4HS is obtained by saturating NH_3Aq with H_2S in absence of air.

$(NH_4)_2S$ is prepared by cooling a mixture of 2 vols. NH_3 and 1 vol. H_2S to −18°; or by distilling K_2S with excess of NH_4Cl and cooling the distillate to −18°.

$(NH_4)_2S_2$ is obtained by passing vapour of S and of NH_4Cl through a hot porcelain tube and then into a well cooled receiver. An aqueous solution may be prepared by dissolving S in $(NH_4)_2S$ Aq in the proportion $(NH_4)_2S{:}S$.

$(NH_4)_2S_5$: when NH_4HSAq (*v. supra*) is digested with S, the solution saturated with NH_3, and then with H_2S, more S added, and saturation with NH_3 and then with H_2S repeated, the whole liquid sets to a crystalline mass; if this is heated to 40°–50° a clear liquid is produced from which, on gradual cooling, large crystals of $(NH_4)_2S_5$ separate out.

$(NH_4)_2S_4$: if the mother liquor from the crystals of $(NH_4)_2S_5$ is surrounded by a freezing mixture, and treated first with NH_3 and then with H_2S a crystalline magma is formed; on warming a clear liquid is produced from which crystals of $(NH_4)_2S_4$ are deposited.

$(NH_4)_2S_7$ is obtained by the gradual decomposition of $(NH_4)_2S_5$ in dry, slightly warm, air; it is also formed when a solution of $(NH_4)_2S_5$ in its mother liquor (*v. supra*) is placed under a large bell jar for some time.

Properties and Reactions.—NH_4SH: hard, white, plates or needles; very soluble in water, and easily volatilised. V.D. at 56° 12·8, which corresponds with equal vols. of H_2S and NH_3 (Deville a. Troost, *C. R.* 56, 891). Aqueous solution is colourless, but soon changes in air from absorption of O, which decomposes a part of the NH_4HS with formation of H_2O, NH_3, and S; some of the S acts on the remaining NH_4HS to form $(NH_4)_2S_2$, another part of the S is oxidised to $H_2S_2O_3$, and a portion of it is usually deposited. This process proceeds if exposure to air is prolonged; the $(NH_4)_2S_2$ is slowly decomposed, until finally a solution of $(NH_4)_2S_2O_3$ in NH_3Aq, mixed with solid S, is the result. NH_4HSAq reacts with most metallic salts in solution to form sulphides of the metals; it also reacts with acidic metallic sulphides to form ammonium thio-salts, with evolution of H_2S, *e.g.* $As_2S_3 + 2NH_4SHAq = 2NH_4AsS_2Aq + H_2S$ (*v.* ARSENIC, THIO-ACIDS OF).

$(NH_4)_2S$: white, lustrous, crystals; easily soluble in water, forming a colourless liquid which easily decomposes with evolution of NH_3 and formation of NH_4HS. V.D. 18·2 (calculated for 2 vols. NH_3 + 1 vol. H_2S = 17·0) (Deville a. Troost, *C. R.* 56, 891). Reacts as a strongly marked base towards acidic sulphides to form ammonium thio-salts.

$(NH_4)_2S_4$: sulphur-yellow crystals, easily soluble in water and alcohol. Stable only in an atmosphere saturated with NH_3 and H_2S; easily decomposed in air with evolution of NH_3 and H_2S. A saturated aqueous solution is fairly stable; more dilute solutions, and solutions in alcohol, soon precipitate S. When heated, NH_4HS and S are formed.

$(NH_4)_2S_5$: orange-red prismatic crystals, easily soluble in water and alcohol. These solutions are very unstable, decomposing into $(NH_4)_2S_2$, S, H_2S, and NH_3, and after some time also $(NH_4)_2S_2O_3$. In dry air the crystals give off NH_3 and NH_4HS and are changed into $(NH_4)_2S_7$.

$(NH_4)_2S_7$: ruby-red crystals, much more stable than any of the lower sulphides; decomposed at about 300°; soluble in water forming a fairly stable liquid which is only slowly decomposed by HClAq.

The liquid known as *fuming liquor of Boyle*, or *volatile liver of sulphur*, chiefly consists of a mixture of various ammonium polysulphides; obtained by distilling a mixture of 1 part S, 2 parts NH_4Cl, and 3 parts CaO. It is a dark yellow, strongly smelling, and strongly fuming, liquid. It dissolves sulphur and then no longer fumes in air.

Ammonia reacts with many metallic salts to form compounds, several of which behave as if they were derivatives of ammonium chloride, sulphate, &c., rather than double compounds of ammonia with the metallic salts in question. Thus NH_3 and $PtCl_2$ form the crystalline compound $PtCl_2.4NH_3$; by the action of H_2SO_4 on this, HCl is evolved, and there is produced $PtSO_4.4NH_3$; decomposed by $Ba(OH)_2Aq$ this compound yields $Pt(OH)_2.4NH_3$, which loses H_2O when heated, with production of $PtO.4NH_3$. The compound $Pt(OH)_2.4NH_3$ is a markedly alkaline body, resembling NaOH or KOH; it neutralises 2 equivalents of a monobasic acid. The compounds $PtCl_2.4NH_3$, $PtSO_4.4NH_3$, and $Pt(OH)_2.4NH_3$, can scarcely be regarded as double compounds of ammonia and platinum salts; their reactions are better suggested by supposing them to be derivatives of ammonium compounds, obtained by replacing part of the hydrogen by platinum. The name platinammonium has been given to the hypothetical radicle

$$N_2H_6Pt. \quad \left(Pt{<}\begin{matrix}NH_3\\NH_3\end{matrix}\right).$$

The chloride of this radicle would be $N_2H_6PtCl_2$; if two hydrogen atoms in the group N_2H_6Pt are supposed to be replaced by two ammonium groups (NH_4) we get the hypothetical radicle ammonium-platinammonium $N_2H_4(NH_4)_2Pt$. The compounds $PtCl_2.4NH_3$, $PtSO_4.4NH_3$, and $Pt(OH)_2.4NH_3$ may be regarded as compounds of this radicle; thus $N_2H_4(NH_4)_2Pt.Cl_2$, $N_2H_4(NH_4)_2Pt.SO_4$, $N_2H_4(NH_4)_2Pt.(OH)_2$.

Compounds are obtained by the action of NH_3Aq on Hg_2Cl_2 and $HgCl_2$, respectively, which have the composition Hg_2NH_2Cl and $HgNH_2Cl$; these react as derivatives of NH_4Cl in which H_2 is replaced by Hg_2 and by Hg, respectively. The name mercuro-ammonium is sometimes given to the hypothetical radicle NH_2Hg_2, and the name mercuri-ammonium to the hypothetical radicle NH_2Hg.

A great many bodies are known the reactions and relations of which can be gathered together into one point of view by considering them as compounds of various hypothetical radicles derived from NH_4, N_2H_8, N_3H_{12}, &c., by replacement of part of the hydrogen by various metals. These compounds will be described under the headings of the various metals (*v.* more particularly the CHROM-AMMONIUM-, COBALT-AMMONIUM-, COPPER-AMMONIUM-, MERCURY-AMMONIUM-, and PLATINUM-AMMONIUM-, COMPOUNDS; in the articles CHROMIUM, COBALT, COPPER, MERCURY, and PLATINUM respectively).

Ammonium salts, *i.e.* derivatives of acids obtained by replacing H by the group NH_4, are described under the various headings CARBONATES, NITRATES, SULPHATES, &c. &c. The principal salts are the following:—*Antimonate; arsenate, arsenite; borate; bromate, &c.; carbamate; carbonates; chlorates, chlorite, &c.; chromates; cyanates; cyanide; iodate, periodate, &c.; molybdates; nitrate, nitrite, &c.; phosphates; selenite, &c.; silicates; sulphamate, &c.; sulphates, sulphites, &c.; tantalate; tellurates; thioarsenates, thiocyanates, thiosulphates, &c.* For an account of the general properties of these salts *v.* beginning of present article.

M. M. P. M.

AMOXY-. Contraction for amyl derivative of OXY-.

AMYDECYLENIC ACID *v.* DECENOIC ACID.

AMYGDALIC ACID $C_{20}H_{26}O_{12}$ or $C_{20}H_{28}O_{13}$. Formed by boiling amygdalin with baryta. Deliquescent crystalline mass, insol. alcohol, and ether. By boiling with H_2SO_4 and MnO_2 it yields formic acid, CO_2, and benzoic aldehyde (Liebig a. Wöhler, *A.* 22, 11; 66, 240; Schiff, *A.* 154, 348).

Acetyl derivatives $C_{20}H_{24}Ac_4O_{13}$ and $C_{20}H_{21}Ac_7O_{13}$ (S.).

AMYGDALIN $C_{20}H_{27}NO_{11}3aq.$ [200°]; after solidifying it melts at 125°–130° (Wöhler, *A.* 41, 155). Mol. w. 511. S. 8·5 at 12°. $[\alpha] = 35{\cdot}5°$.

Occurrence.—In bitter almonds (Robiquet a. Boutron, *A. Ch.* [2] 44, 352); to a small extent in sweet almonds; in laurel leaves (*Cerasus lauro-cerasus*); in the leaves, blossoms, and bark of the birdcherry (*Prunus padus*); in young shoots of the apple tree; and in the kernels of apples, pears, and peaches (Riegel, *A.* 48, 361; Wicke, *A.* 79, 79; 81, 241; Lehmann, *N. R. P.* 23, 449).

Preparation.—The almond-cake from which the fatty oil of almonds has been removed by pressure is extracted with boiling alcohol; the filtrate is concentrated and the amygdalin ppd. by ether.

Properties.—White pearly scales or thin prisms (from water). Insol. ether.

Reactions.—1. Under the influence of emulsin or of boiling dilute H_2SO_4 it is split up into benzoic aldehyde, prussic acid, and glucose (Liebig a. Wöhler, *A.* 22, 17): $C_{20}H_{27}NO_{11} + 2H_2O = C_7H_6O + CNH + 2C_6H_{12}O_6$.—2. $KMnO_4$ forms cyanic and benzoic acids.—3. *Potash* or *baryta* form amygdalic acid.—4. Conc. HCl gives mandelic acid, glucose, and NH_3.—5. PCl_5 gives CyCl and benzylidene chloride.—6. Zn and dilute hydrochloric acid give $C_6H_5.CH_2.CH_2.NH_2$ (Fileti, *B.* 12, 297).

Acetyl derivative $C_{20}H_{20}Ac_7NO_{11}$. Long needles (from alcohol); insol. water (Schiff; *A.* 154, 338).

Amorphous amygdalin has been described by Winckler (*B. J.* 20, 428), Neumann (*B. J.* 23, 503), Simon (*A.* 31, 263), and Lehmann (*loc. cit.*).

AMYL C_5H_{11}. *Pentyl.* A monovalent basylous radicle which can occur in eight forms:
n-amyl, $CH_3.CH_2.CH_2.CH_2.CH_2$;
iso-butyl-carbinyl $(CH_3)_2CH.CH_2.CH_2$;
sec-butyl carbinyl, $(CH_3)CH(C_2H_5).CH_2$;
tert-butyl-carbinyl $(CH_3)_3C.CH_2$;
methyl-*n*-propyl-carbinyl, $CH_3.CH_2.CH_2C(CH_3)H$;
methyl-isopropyl-carbinyl, $(CH_3)_2CH.C(CH_3)H$;
di-ethyl-carbinyl $(C_2H_5)_2CH$;
and di-methyl-ethyl-carbinyl $(CH_3)_2(C_2H_5)C$.
Ordinary amyl alcohol is a mixture of *iso*-butyl-carbinol and sec-butyl carbinol, and it is from this mixture that most of the amyl compounds have been prepared. The term 'iso-amyl' compounds will, for the sake of brevity, be used in this dictionary to denote the mixture of amyl

compounds prepared from this source. Inasmuch as the proportion of the two constituents of 'isoamyl' alcohol varies with its source, 'isoamyl' compounds prepared by different chemists can hardly be expected to possess identical physical characters. Amyl derivatives of hydroxylic carbon compounds are described under the compounds of which they are the ethers.

Di-amyl $(C_5H_{11})_2$ or $C_{10}H_{22}$ *v.* DECANE.

AMYL-ACETYLENE *v.* HEPTINENE.

AMYL ALDEHYDE *v.* VALERIC ALDEHYDE.

AMYL ACETATES $C_7H_{14}O_2$. *Pentyl acetates.* Mol. w. 130.

Preparation. — Similar to that of ethyl acetate, p. 14.

***n*-Amyl acetate.** (147·6°) (Gartenmeister, *A.* 233, 260); (148·4°) at 737 mm. (Lieben a. Rossi, *A.* 159, 74). S.G. $\frac{0}{0}$ ·8948; $\frac{20}{20}$ ·8774 (G.). C.E. (0°–10°) ·00106 (G.). S.V. 173·8 (G.). Prepared from *n*-amyl iodide and silver acetate.

Iso-amyl acetate. (137·6°) at 745 mm.; (138·9°) (R. Schiff, *A.* 220, 110). S.G. $\frac{15}{4}$ ·8762 (Mendeléeff, *J.* 1860, 7); $\frac{20}{4}$ ·8561 (Brühl). μ_β 1·4088 (B.). R∞ 59·7 (B.) S.V. 174·6 (S.). Is largely used as a flavouring agent to imitate jargonelle pears.

Methyl-propyl-carbinyl acetate. (133°–135°) (Wurtz, *A.* 148, 132); (134°–137°) (Schorlemmer, *A.* 161, 269). S.G. $\frac{0}{}$ ·922 (W.).

Methyl-isopropyl-carbinyl acetate. (125°) (Wurtz, *A.* 129, 367).

Di-ethyl-carbinyl acetate. (132°) at 741mm. S.G. $\frac{0}{}$ ·909 (Wagner a. Saytzeff, *A.* 175, 306).

Tert-amyl acetate. (124°) at 750 mm. S.G. $\frac{0}{}$ ·891 (Flawitzky, *A.* 179, 348). Decomposed by heat into amylene and acetic acid (Menschutkin, *C. R.* 95, 648).

AMYL ALCOHOLS $C_5H_{12}O$. Mol. w. 88. Theory indicates 8 amyl alcohols (*v.* AMYL), viz.: 4 primary, 3 secondary, and 1 tertiary. One of these, tert-butyl carbinol, is unknown.

***n*-Amyl alcohol** $CH_3.CH_2.CH_2.CH_2.CH_2.OH$. (137°) at 740 mm. (Lieben a. Rossi, *C. R.* 71, 370); (137·9° i. V.) (Zander, *A.* 224, 81). S.G. $\frac{0}{0}$ ·8282 (Z.). C.E. (0°–10°) ·00091 (Z.) S.V. 123·4 (Z.).

Occurrence.—In fusel oil (Wyschnegradsky, *A.* 190, 350).

Formation.—1. From *n*-valeric aldehyde and sodium amalgam (L. a. R.).—2. From *n*-amyl chloride (Schorlemmer, *A.* 161, 268).

Inactive amyl alcohol
$(CH_3)_2CH.CH_2.CH_2OH$. (130·5°–131·2°) (Lachowicz, *A.* 220, 171); (131·5° cor.) (Perkin). S.G. $\frac{15}{15}$ ·8135; $\frac{25}{25}$ ·8078 (P.). M.M. 5·959 at 18·6° (P.). Fusel oil is a mixture of active and inactive amyl alcohol; they can be more or less separated either by passing HCl into the boiling alcohol, when the inactive alcohol is converted into amyl chloride more readily than its isomeride (Le Bel, *C. R.* 77, 1021); or by means of the barium salts of the two amyl-sulphuric acids, $C_5H_{11}SO_4H$, the active salt being the more soluble in water (Pasteur, *C. R.* 41, 296). The simplest way to obtain an inactive amyl alcohol is carefully to fractionate fusel oil (L.). *The same alcohol can be prepared from isobutyl alcohol by converting it first into valeric acid (Balbiano, G. 6, 229).*

Iso-amyl alcohol.

mixture of** $(CH_3)_2CH.CH_2.CH_2OH$* **and** $(CH_3)CH(C_2H_5).CH_2OH$. ***Fermentation amyl alcohol. Fusel oil. [c. −134°] (Olszewski, *M.* 5, 128). (130·5°–131°) (R. Schiff, *A.* 220, 102). S.G. $\frac{20}{4}$ ·8104 (Brühl, *A.* 203, 23). S.H. ·679 (Diaconoff, *Bl.* [2] 38, 172). *Latent heat of vaporisation* 123·8 (D.). S. 2·5 at 16°. H.F.p. 74,890 (Thomsen). H.F.v. 71,700 (T.). μ_β 1·4124. R_∞ 43·08. S.V. 122·7 (S.). *Critical temperature* 307° (Pawlewski, *B.* 16, 2634).

Occurrence.—Formed in small quantity in the alcoholic fermentation of saccharine liquids. Isoamyl angelate and isoamyl tiglate occur in Roman oil of chamomile (Köbig, *A.* 195 99).

Properties.—Poisonous liquid with powerful odour. Its detection in alcohol is described on p. 96. It burns with smoky flame.

Decomposition.—1. Its vapour led through a *red-hot tube* produces acetylene, ethylene, propylene, and butylene (Wurtz, *A.* 104, 242).—2. S_2Cl_2 gives amyl chloride and amyl sulphite (Carius a. Fries, *A.* 109, 1).—3. PCl_3 and PCl_5 form amyl chloride.—4. *Potash-lime* at 220° gives hydrogen and potassic valerate.—5. $ZnCl_2$ produces amylene (*q. v.*). Hot H_2SO_4 and P_2O_5 act similarly.—6. Poured upon *bleaching powder*, it reacts in less than an hour; the distillate decomposes with evolution of Cl_2 and HCl, and then contains amyl alcohol, valeric aldehyde, and amyl valerate (Goldberg, *J. pr.* [2] 24, 116).

Compounds.—$(C_5H_{12}O)_2SnCl_4$. Deliquescent crystalline plates, decomposed by water (Bauer a. Klein, *A.* 147, 249).—$C_5H_{12}O,SbCl_5$.—Crystalline.—$(C_5H_{12}O)_3CaCl_2$ (Heindl, *M.* 2, 209).

Sodic amylate, $C_5H_{11}NaO,2C_5H_{12}O$ (Fröhlich, *A.* 202, 295). At 165° it combines with CO forming sodic isovalerate and the sodium salt of an acid $C_{10}H_{18}O_2$. CO passed over a mixture of $NaOC_5H_{11}$ and NaOAc at 180° produces sodic formate and the sodium salts of a variety of acids, the principal being iso-heptoic acid (*q. v.*) formed by substitution of H of acetic acid by C_5H_{11}. Another product is oxy-vinyl-heptoic or oxy-ennenoic acid (*q. v.*). An acid crystallising in needles $C_{11}H_{18}O_4$ [139°] is also formed; its empirical formula is that of di-acetyl-heptoic acid (Poetsch, *A.* 218, 56).

Potassium amylate $C_5H_{11}OK$. White silky crystals (de Forcrand, *C. R.* 104, 68).

Thallium amylate $C_5H_{11}OTl$. S.G. 2·5. An oil obtained by heating thallium ethylate with amyl alcohol.

Aluminium amylate $Al(OC_5H_{11})_3$. [70°]. S.G. $\frac{4}{}$ ·9801. Formed by action of AlI_3 and iodine (Gladstone a. Tribe, *C. J.* 39, 7; *v.* ALUMINIUM IODIDE, p. 148).

Active amyl alcohol $CEtMeH.CH_2OH$. (128°) (Pedler, *A.* 147, 243); (127°–128°) (Just, *A.* 220, 149). a_D −2·3° (J.); −4·4° (Le Bel; Pierre a. Puchot).

Occurrence.—In fermentation amyl alcohol, which is thus rendered more or less lævorotatory.

Preparation.—Described under inactive amyl alcohol.

Properties.—In a sample for which *a* was only −1·14°. Perkin (*C. J.* 45, 470) found S.G. $\frac{15}{15}$ *·8150; $\frac{25}{25}$ ·8091*; and M.M. *5·94* at 20°. A rotation *of more than 4·4° to the left* (in a tube 100 mm. long) *has been observed by Ley (−11·5°), and by Pedler (−8·6°).*

Reactions.—1. A dilute solution mixed with **yeast, *penicillium glaucum*, and a little** H_2SO_4

becomes dextrorotatory. The new dextrorotatory amyl alcohol forms a lævorotatory iodide (Le Bel, *Bl.* 31, 104).—2. On *oxidation* it yields a dextrorotatory valeric acid, boiling at 170° (Pedler).—3. Hot NaOH renders it inactive.

References.—Pasteur, *C. R.* 41, 296; *A.* 96, 255; Popoff, *B.* 6, 560; Ley, *B.* 6, 1362; Erlenmeyer a. Hell, *A.* 160, 257; Pierre a. Puchot, *C. R.* 76, 1332; Bakhoven, *J. pr.* [2] 8, 272; Le Bel, *B.* 6, 70; 9, 358, 732; *C. R.* 82, 562; *Bl.* 25, 545; Pedler, *A.* 147, 243; Chapman a. Smith, *Pr.* 17, 308.

Methyl-*n*-propyl-carbinol Pr.CMeH.OH (119°). S.G. ^{0} ·824. S. 13·7.

Formation.—1. From its iodide.—2. By reducing methyl propyl ketone with sodium-amalgam (Belohoubek, *B.* 9, 924). So prepared it is inactive, but if it be dissolved in 20 pts. water and *penicillium glaucum* be introduced, it becomes lævorotatory (α −5·5°) (Le Bel, *C. R.* 89, 312).—3. From acetyl chloride and zinc propyl (Markownikoff, *Bl.* [2] 41, 259).

Reactions.—1. *Oxidation* gives methyl propyl ketone.—2. Gives the iodoform reaction.

Methyl-isopropyl-carbinol. Pr.CMeH.OH. (113°). S.G. ^{0} ·833 (Wischnegradsky, *A.* 190, 338).

Formation.—1. From methyl isopropyl ketone with sodium-amalgam (Münch, *A.* 180, 339).—2. By adding water to the product of the action of zinc methide on bromo-acetyl bromide (Winogradoff, *A.* 191, 125), or chloro-acetyl chloride (Bogomoletz, *A.* 209, 86; *Bl.* [2] 34, 330).

Reactions.—1. Conc. H_2SO_4 forms tri-methyl-ethylene, Me_2C:CMeH, which may be converted by warm conc. HI into the iodide of tertiary amyl alcohol.—2. *Oxidation* gives methyl isopropyl ketone, acetone, acetic acid, and CO_2.—3. PCl_5 forms a chloride (87°).

Di-ethyl carbinol Et_2CH.OH. (117°). S.G. ^{0} ·832. Formed by adding water to the product of the action of zinc ethide on ethyl formate (Wagner a. Saytzeff, *A.* 175, 351). The first reaction may be written HCO.OEt + 2ZnEt_2 = HCEt(OZnEt)Et + ZnEt(OEt). Water then displaces OZnEt by OH. It gives di-ethyl ketone on oxidation.

Tertiary amyl alcohol Et.CMe_2.OH. *Di-methyl-ethyl-carbinol. Amylene hydrate.* [−12°]. (102° cor.) (Perkin, *C. J.* 45, 471). S.G. $\frac{15}{15}$ ·8144; $\frac{25}{25}$ ·8070 (P.). M.M. 5·99 at 19°. H.F.p. 84,510. H.F.v. 81,320 (*Th.*). S.V. 121·3 (R. Schiff, *A.* 220, 102).

Formation.—1. From tertiary amyl iodide (*q. v.*).—2. From zinc methide and propionyl chloride (Popoff, *A.* 145, 292; Jermolajeff, *Z.* 1871, 275; Wyschnegradsky, *A.* 190, 336).

Preparation.—Amylene (1 vol.), prepared from ordinary amyl alcohol, is shaken with an ice-cold mixture of water (1 vol.) and H_2SO_4 (1 vol.).

Reactions.—1. On *oxidation* it gives rise to acetone and acetic acid.—2. When introduced into the stomach (of a rabbit) it is excreted as a glycuronate, $C_{11}H_{20}O_7$, which is split up by acids into the alcohol and glycuronic acid (Thierfelder a. Mering, *H.* 9, 515).—3. Slowly decomposed by *heat* at 220° into H_2O and amylene; this decomposition does not take place unless traces of HCl or HI are present (Wolkoff a. Bougaieff, *J. R.* 1885, 276).

AMYLAMINES $C_5H_{13}N$.

Normal Amylamine
$CH_3.CH_2.CH_2.CH_2.CH_2.NH_2$ (103°).

Formation.—From the amide of normal hexoic acid by the action of bromine and potash (Hofmann, *B.* 15, 770). A mixture of 1 mol. proportion amide and 1 mol. bromine is run into excess of 10 p.c. solution of potash at 60°.

AMYLAMINES FROM AMYL ALCOHOL OF FERMENTATION:—

Ordinary Amylamine
$(CH_3)_2.CH.CH_2.CH_2.NH_2$ (95°–96°). S.G. ^{18} ·7503. S.V. 126·84 (Schiff).

Formation.—1. Amyl cyanate or cyanurate with potash (Wurtz, *A. Ch.* [3] 30, 447; Brazier and Gossleth, *A.* 75, 252).—2. Dry distillation of animal substances (Anderson, *A.* 105, 335).—3. Dry distillation of leucine (Schwanert, *A.* 102, 225).—4. Amylsulphate of potassium with alcoholic ammonia at 250° (Berthelot, *A.* 87, 372).—5. Distillation of horn with aqueous potash (Limpricht, *A.* 101, 296).—6. Caustic potash on flannel (Gr. Williams, *Chem. Gaz.*, 1858, 310).—7. Amide of isohexoic acid (isobutylacetamide) with bromine and aqueous potash (Hofmann, *B.* 15, 770).—8. In the decomposition of yeast (Müller, *J.* 1857, 403).

Preparation.—Amyl bromide is heated to 100° with alcoholic ammonia in large excess, the alcohol evaporated and the residual hydrobromides decomposed with potash. The oily layer which consists of mono-, di-, and some tri-, amylamine, is dried with caustic baryta and fractionated. Or, potassium amyl sulphate is distilled with potassium cyanate; the resulting amyl cyanate and cyanurate distilled with strong potash; the distillate neutralised with hydric chloride, evaporated and crystallised; and the amylamine obtained by distilling the hydrochloride with lime (Wurtz; Silva, *Bl.* [2] 8, 363).

Properties.—Colourless liquid, miscible with water and alcohol.

Reactions.—1. Oxidised by *chromic acid* to isovaleric acid (Chapman a. Thorpe, *A.* 142, 177).—2. With $ClCO_2Et$ yields ethyl-amyl-carbamate, $C_5H_{11}NHCO_2Et$ (amylurethane) (Custer, *B.* 12, 1329).

Salts.—B'HCl: scales; sol. alcohol.—$B'_2H_2PtCl_6$: scales; sol. hot water, insol. alcohol.—Aurochloride: scales.

Combination.—With *carbonic disulphide* it forms $C^{11}H^{26}N^2S^2(2C^5H^{13}N + CS^2)$ white shining scales, insol. water and ether, sol. alcohol (Hofmann, *C. J.* 13, 60).

Active Amylamine.—The amylamines obtained from active amyl alcohol, probably $(C_2H_5)(CH_3)CH.CH_2OH$ (Erlenmeyer; *v.* AMYL ALCOHOLS; Sauer, *B.* 8, 1037), are optically active, and their salts are much more difficult to crystallise than are those of the corresponding inactive compounds (Plimpton, *C. J.* 39, 332). Amylamine from alcohol rotating 4° for 10 cm. rotated 3° 30′ to the left; (96°–97°); S.G.^{0} $\frac{2}{4}$ ·7725.—*Hydrochloride*: deliquescent; feebly dextrogyrate.—*Platino-chloride*: scales; sol. hot water. S. 2·4 at 14°.—*Aurochloride*: sol. alcohol; separates on slow evaporation in lozenge-shaped crystals with the acute angles truncated.

Inactive Amylamine from inactive amyl chloride. (96°-97°). S.G. $\frac{0}{4}$ ·7678; $\frac{22·5}{4}$ ·7501. —*Hydrochloride*: crystallises well.—*Platinochloride* S. 1·7 at 14°: scales.—*Aurochloride*: sol. alcohol; lozenge-shaped crystals with one acute angle truncated.

Diamylamine $(C_5H_{11})_2NH$. (186°-187°). S.G. ^{0} ·7825 (Silva).

Formation.—1. From ord. amylamine and ord. amyl bromide (Hofmann, *A.* 79, 21).—2. From amyl cyanide and potash (Silva, *Z.* 1867, 457). 3. From amyl bromide and alcoholic ammonia (Custer, *B.* 12, 1329; Plimpton, *C. J.* 39, 332; Bell, *B.* 10, 1867).—4. From amyl chloride and aqueous NH_3 at 140°-165° (Mallot, *C. R.* 104, 998).—5. From the nitroso-compound (Custer, *B.* 12, 1333).

Properties.—Oily liquid; sl. sol. water. Reacts with $Cl.CO_2Et$ yielding diamylurethane (Custer).

Salts.—B′HCl: laminæ; crystallises well from hot water.—$(B'HCl)_2PtCl_4$: sol. alcohol, sl. sol. water. Auro-chloride: sol. alcohol, insol. water.

Active Di-amylamine. (182°-184°). S.G. $\frac{0}{4}$ ·7878. From active amyl bromide. (*V.* active amylamine) (Plimpton, *loc. cit.*) Dextrorotatory (5° 15′ for 10 cm.).

Hydrochloride: soluble in water, alcohol, and ether. Much more soluble in cold water than the inactive salt. Solution rotates to the right. *Platinochloride*: sol. alcohol, insol. water. Crystallises from dilute alcohol in octahedrons. *Aurochloride*: insol. water, sol. alcohol.

Inactive Di-amylamine. (186°-187°). S.G. $\frac{0}{4}$ ·7878; $\frac{14}{4}$ ·7776. From inactive amyl chloride (Plimpton).

Hydrochloride: laminæ; rotates when thrown on the surface of water. Insol. ether.—*Platinochloride*: sol. alcohol, insol. water. Crystallises easily from dilute alcohol in rectangular prisms.

Triamylamine $(C_5H_{11})_3N$. (237°). From diamylamine and amyl bromide or from amyl bromide and ammonia (Hofmann, *A.* 79, 22). Amyl cyanate and potash (Silva, *Z.* 1867, 458). Oily liquid, insol. water.

Salts. — B′HCl: crystalline mass with lustre of mother-of-pearl. Platinochloride: rhombic prisms; insol. water, sol. alcohol.

Active Triamylamine. (230°-237°). S.G. $\frac{13}{4}$ ·7964. Prepared from active amyl bromide (3°) and active diamylamine (5° 15′). Rotates 44° 15′ to the right for 10 cm. (Plimpton, *loc. cit.*).

Hydrochloride: syrup which solidifies over sulphuric acid. Solution strongly dextrogyrate.

Aurochloride: needles; insol. water, sol. alcohol.

Inactive Triamylamine. (237°). S.G. $\frac{13}{4}$ ·788. From inactive amyl chloride and ammonia.

Hydrochloride: crystallises from water in prismatic needles, from ether in pearly scales.—*Aurochloride*: needles; sol. alcohol. Inactive triamylamine may be separated from inactive diamylamine by treating the hydrochlorides with ether which dissolves the triamylamine salt.

Tetramylammonium Salts.

Iodide $(C_5H_{11})_4NI$. From ordinary amyl iodide and triamylamine or amyl iodide and ammonia (Hofmann, *C. J.* 4, 316). The mixture of triamylamine and amyl iodide is boiled and after three or four days solidifies on cooling into an unctuous crystalline mass. Monoclinic laminæ (Lang, *J.* 1867, 491). Dissolves sparingly in water forming an extremely bitter solution from which it is ppd. in a crystalline form by alkalis. Boiled with silver oxide it yields a very bitter alkaline solution of *Tetramylammonium hydroxide.* On mixing the liquid with potash or on concentrating, the hydroxide separates as an oily layer, which gradually solidifies. By evaporating a solution of the hydroxide in an atmosphere free from carbonic acid, crystals containing several molecules of water are obtained. When heated these crystals melt and give off water, triamylamine, and a hydrocarbon which is probably amylene.

$(C_5H_{11})_4NCl$: laminæ with palm-like ramifications. — $((C_5H_{11})_4NCl)_2PtCl_4$: orange-yellow needles.—*Sulphate*: long capillary threads.—*Nitrate*: needles. — *Oxalate*: large deliquescent plates.

Amylamine. Corresponding to methyl propyl carbinol. $(CH_3)(C_3H_7)CHNH_2$. (89°-91°). By reduction of methyl propyl ketone phenyl hydrazide in alcoholic solution with sodium amalgam and acetic acid (Tafel, *B.* 19, 1924). Mobile liquid, smelling strongly ammoniacal, miscible with water, alcohol, and ether.

Hydrochloride: silky needles. — *Platinochloride*: yellow needles; sol. water and hot alcohol, less so in cold alcohol.—*Oxalate*: crystallises from hot alcohol in scales.

Tertiary amylamine. $(CH_3)_2(C_2H_5)CNH_2$. (77·5°-78°). S.G. ^{0} ·7611; $^{15·5}$ ·7475. Formerly considered to be $(CH_3)_2CH(CH_3)CHNH_2$ on account of its formation from the cyanate corresponding to Wurtz's amylene hydriodide and amylene hydrate, then regarded as isopropyl-methyl carbinol, and now shown to be dimethyl-ethyl carbinol (Flavitzky, *A.* 179, 310).

Formation.—1. From pseudoamylurea and strong potash (Wurtz, *Bl.* [2] 7, 143).—2. By the action of dimethyl ethyl carbinol iodide on the cyanides of potassium and mercury, and treatment of the nitrile so obtained with hydric chloride (Wyschnegradsky, *A.* 174, 60).—3. By treating the product of the action of the same iodide upon silver cyanate with strong hydric chloride (Rudnew).

Properties.—Odour ammoniacal; pps. copper salts but does not redissolve the ppd. cupric hydrate.

Hydrochloride: efflorescent scales, or octahedrons, from alcohol and ether. — *Platinochloride*: fine crystals derived from a monoclinic prism, easily soluble water and alcohol. — *Aurochloride*: large yellow crystals, monoclinic.

Reactions. — With bromine it forms bromamyl-amine $C_5H_{12}BrN$ which can be distilled with steam (Wurtz). R. T. P.

AMYL-ANILINE $C_{11}H_{17}N$ *i.e.* $C_6H_5.NHC_5H_{11}$. (258°). Mol. w. 163. From aniline and isoamyl bromide (Hofmann, *C. J.* 3, 297). Smells, when cold, like roses. When its hydrochloride is heated at 320° it changes to the hydrochloride of amido-phenyl-pentane, $C_5H_{11}.C_6H_4.NH_2$ (Hofmann, *B.* 7, 529).

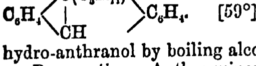
Isoamyl-aniline $C_6H_5.NHC_5H_{11}$ (243°) at 720 mm. Colourless oil. V. sol. alcohol, ether, and benzene, insol. water. Is a by-product of the action of isovaleric aldehyde and HCl upon aniline. Salts.—B'HCl: colourless prisms, v. sol. water. The nitrate and oxalate are sparingly soluble. The picrate is a reddish-yellow oil.

Acetyl derivative $C_6H_5.N(C_5H_{11})Ac$, (278°) at 720 mm., colourless fluid, v. sol. alcohol and ether; insol. water.

Nitrosamine $C_6H_5.N(C_5H_{11})NO$: oil; volatile with steam; v. sol. alcohol and ether, insol. water (Spady, *B.* 18, 3376).

Di-isoamyl-aniline $C_6H_5N(C_5H_{11})_2$. (275°–280°) (Hofmann, *A.* 74, 156). –$B'_2H_2PtCl_6$.

Iso-**AMYL-ANTHRACENE** $C_{19}H_{20}$ *i.e.*



$C_6H_4\left\langle\begin{matrix}C(C_5H_{11})\\|\\CH\end{matrix}\right\rangle C_6H_4$.

[59°]. From amyl-hydro-anthranol by boiling alcoholic HCl.

Preparation.—Anthraquinone (30 g.), zinc dust (100 g.) NaOH (50 g.), water (450 g.) are boiled together for 5 hours and then amyl bromide is added. The liquid is poured off, and the pp. dissolved in alcohol, reppd. by water, and boiled with alcoholic HCl (Liebermann, *A.* 212, 104; *B.* 14, 796).

Properties.—Long sea-green needles with blue fluorescence (from alcohol). Conc. H_2SO_4 gives a green solution. V. sol. benzene, CS_2, chloroform, or benzoline. *Picrate* forms red needles [115°], CrO_3 in HOAc gives amyl-oxanthranol. Forms a *bromo compound*

$C_6H_4\left\langle\begin{matrix}C(C_5H_{11})\\CBr\end{matrix}\right\rangle C_6H_4$.

[76°]. Picrate [110°]. Forms also a corresponding *chloro-derivative* [71°]. Picrate [108°].

Iso-**Amyl-anthracene-di-hydride** $C_{19}H_{22}$ *i.e.*

$C_6H_4\left\langle\begin{matrix}CH(C_5H_{11})\\CH_2\end{matrix}\right\rangle C_6H_4$.

(350°); (292°) at 570 mm. S.G. $\frac{18}{18}$ 1·031. Prepared by reduction of amyl-oxanthranol with P and HI (Liebermann, *B.* 14, 457; 15, 1000; *A.* 212, 79). Clear fluorescent liquid. Miscible with alcohol, ether, benzene, and acetic acid, in all proportions. On oxidation with HNO_3 anthraquinone is formed.

Iso-**AMYL ARSENATE** $(C_5H_{11})_3AsO_4$ (Crafts, *Bl.* 14, 101).

Iso-**AMYL ARSENITE** $(C_5H_{11})_3AsO_3$. (288°) (Crafts, *Bl.* 14, 105).

n-**AMYL-BENZENE.** *Phenyl-pentane.* $C_{11}H_{16}$ *i.e.* $Ph.CH_2.CH_2.CH_2.CH_2.CH_3$. Mol. w. 148. (201° uncor.) at 743 mm. S.G. $\frac{22}{}$ ·8602. From benzyl bromide, *n*-butyl bromide, and sodium (Schramm, *A.* 218, 388). Pleasant smelling oil.

Reaction.—Bromine vapour at 150° gives $Ph.CHBr.CH_2.CH_2.CH_2.CH_3$ (?) which on distillation gives $Ph.CH:CH.CH_2.CH_2.CH_3$ (210°–215°) which combines with Br_2 forming $Ph.CHBr.CHBr.CH_2.CH_2.CH_3$. [54°].

Isoamyl-benzene (193°) at 736 mm. S.G. $\frac{12}{}$ ·859. From bromo-benzene, isoamyl bromide, and Na (Fittig a. Tollens, *A.* 129, 369; 131, 313; Bigot a. Fittig, *A.* 141, 160; Schramm, *A.* 218, 390). Also from isoamyl chloride, benzene, and $AlCl_3$ (Friedel a. Crafts, *A. Ch.* [6] 1, 454).

Reaction.—Bromine vapour at 150° gives $Ph.CHBr.CH_2.CH(CH_3)_2$(?) which on distillation gives HBr and $Ph.CH:CH.CH(CH_3)_2$, phenyl-isoamylene, which forms a dibromide [129°].

Di-ethyl-carbinyl-benzene $Ph.CHEt_2$. (178°). S.G. $\frac{21}{}$ ·873.

Formation.—1. From benzylidene chloride and zinc ethide (Lippmann a. Luginin, *Z.* 1867, 674).—2. From benzo-trichloride, $Ph.CCl_3$, and zinc ethide (Dafert, *M.* 4, 153, 616).

Tert-**amyl-benzene** $Ph.CMe_2Et$. (c. 187°). S.G. $\frac{0}{}$ ·874. From tert-amyl chloride, benzene, and $AlCl_3$ (Essner, *Bl.* [2] 36, 212).

Di-isoamyl-benzene $C_{16}H_{26}$ *i.e.* $(C_5H_{11})_2C_6H_4$. (c. 265°). S.G. $\frac{0}{}$ ·887. From benzene, isoamyl chloride, and $AlCl_3$ (Austin, *Bl.* [2] 32, 12).

AMYL-BENZENE SULPHONIC ACIDS $C_{11}H_{16}SO_3$ *i.e.* $C_5H_{11}.C_6H_4SO_3H$.

Isoamyl-benzene sulphonic acid. Deliquescent crystalline mass (Fittig a. Tollens, *A.* 131, 315). Salts.—KA' aq.—BaA'_2: hair-like needles.

Di-ethyl-carbinyl-benzene sulphonic acid $CHEt_2.C_6H_4.SO_3H$. Salts.—BaA'_2 1½aq: pearly leaflets, sl. sol. water and alcohol (Dafert, *M.* 4, 617).

p-*Iso*-**AMYL-BENZOIC ACID** $C_{12}H_{16}O_2$ *i.e.* $C_6H_4(C_5H_{11}).CO_2H$ [1:4] [158°]. Formed by saponification of the nitrile. Sublimes in flat colourless needles. Sol. alcohol, ether, and hot water, sl. sol. cold water. Salt: AgA': small colourless needles, sl. sol. cold water (Kreysler, *B.* 18, 1710).

p-*Iso*-**AMYL-BENZONITRILE** $C_6H_4(C_5H_{11}).CN$ (260°–263° uncorr.). Colourless oil. Formed by heating tri-isoamylphenyl-phosphate with dry KCN; yield—20 p.c. (Kreysler, *B.* 18, 1709).

Iso-**AMYL BORATE** $C_{15}H_{33}BO_3$ *i.e.* $(C_5H_{11}O)_3B$. (254°). S.G. $\frac{0}{}$ ·872.

Iso-amyl borate $(C_5H_{11}O)BO$. S.G. $\frac{0}{}$ ·971. Oil.

n-**AMYL BROMIDE** $C_5H_{11}Br$ *i.e.* $CH_3.CH_2.CH_2.CH_2.CH_2Br$. Mol. w. 151. (129°). S.G. $\frac{0}{}$ 1·246. From *n*-amyl alcohol (Lieben a. Rossi, *A.* 159, 73).

Inactive amyl bromide $(CH_3)_2CH.CH_2.CH_2Br$ (120·6° i. V.) at 734 mm. S.G. $\frac{22}{}$ 1·026 (Lachowicz, *A.* 220, 171).

Isoamyl bromide (118·5°) at 756 mm. (R. Schiff, *B.* 19, 563). H.F.p. 34,000 (Berthelot). S.V. 138·6 (S.); 143·8 (Ramsay). For a specimen which rotated + ·52° in 100 mm. Perkin (*C. J.* 45, 458) found: (120·5° cor.); S.G. $\frac{15}{15}$ 1·2193; $\frac{25}{25}$ 1·2083; M.M. 9·04 at 17°.

Active amyl bromide (117°–120°); S.G. $\frac{15}{}$ 1·225 (Le Bel, *Bl.* [2] 25, 545). Dextrorotatory; $\alpha = +3·75°$.

n-*Sec*-**amyl bromide** $CH_3.CH_2.CH_2.CHBr.CH_3$. (113°) (Wurtz, *A.* 125, 118). Formed when isoamyl bromide is heated at 230° (Eltekow, *B.* 8, 1244).

Iso-*sec*-**amyl bromide** $(CH_3)_2CH.CHBr.CH_3$. (116°) (Wyschnegradsky, *A.* 190, 357).

Tert-**amyl bromide** $CH_3.CH_2.CBr(CH_3)_2$. (109°).

AMYL-BROMO- *v.* BROMO-AMYL.

Iso-**AMYL-CARBAMIC ETHER** $C_8H_{17}NO_2$ *i.e.* $C_5H_{11}NHCO_2Et$. *Amyl-urethane.* (218°). S.G. ·93. From isoamyl-amine and $ClCO_2Et$ (Custer, *B.* 12, 1328). Oil; sol. alcohol and ether.

Di-isoamyl-carbamic ether $(C_5H_{11})_2N.CO_2Et$. (247°). From di-isoamyl-amine and $ClCO_2Et$ (C.).

***Iso*-AMYL CARBAMINE** $C_6H_{11}N$ *i.e.* $C_5H_{11}NC$. (137°). Mol. w. 97 (Hofmann, *A.* 146, 109).

***Iso*-AMYL CARBONATE** $C_{11}H_{22}O_3$ *i.e.* $(C_5H_{11})_2CO_3$ (229° cor.). S.G. $\frac{15}{}$ ·91.

***Iso*-AMYL CETYL OXIDE** $C_{21}H_{44}O$ *i.e.* $C_5H_{11}OC_{16}H_{33}$. [30°]. Plates.

***n*-AMYL CHLORIDE** $C_5H_{11}Cl$ *i.e.* $CH_3.CH_2.CH_2.CH_2.CH_2Cl$. Mol. w. 106·5. (106°). S.G. $\frac{20}{}$ ·873 (Lachowicz, *A.* 220, 191); ·883 (L. a. R.). Formed from *n*-amyl alcohol (Lieben a. Rossi, *A.* 159, 72; *G.* 1, 314) or by the chlorination of *n*-pentane (Schorlemmer, *A.* 161, 268).

Inactive amyl chloride $(CH_3)_2CH.CH_2.CH_2Cl$. (99·8°–100·5°). S.G. $\frac{20}{}$ ·870. From iso-pentane (Lachowitz).

Iso-amyl chloride (99·5°) (R. Schiff, *B.* 19, 562). S.V. 134·4 (S.); 136·5 (Ramsay). In a specimen which rotated +5·8° in 100 mm. Perkin (*C. J.* 45, 452) found: (97°–99° cor.); S.G. $\frac{15}{15}$ ·8801; $\frac{25}{25}$ ·8716; M.M. 7·17 at 19·5°.

Formation.—1. From isoamyl alcohol and HCl (Balard, *A. Ch.* [3] 12, 294), S_2Cl_2 (Carius a. Fries, *A.* 109, 1), or PCl_5 (Cahours, *A.* 37, 164).

Reactions.—1. Converted into amyl alcohol by water at 100° (Butlerow, *A.* 144, 34), or better at 120° (Niederist, *A.* 186, 392).—2. H_2SO_4 forms HCl and $C_5H_{11}SO_4H$ (Oppenheim, *J. pr.* 102, 339).

Active amyl chloride $CH_3.CH_2.CH(CH_3).CH_2Cl$. (99°). $\alpha = +1·24°$. S.G. $\frac{15}{}$ ·886 (Le Bel, *Bl.* [2] 25, 546).

***n-Sec*-amyl chloride** $CH_3.CH_2.CH_2.CHCl.CH_3$. (104°). S.G. $\frac{21}{}$ ·891. From *n*-pentane by chlorination (Schorlemmer; Lachowicz). From $CH_3.CH_2.CH:CH.CH_3$ and HCl (Wagner a. Saytzeff, *A.* 179, 321).

***Iso-sec*-amyl chloride** $(CH_3)_2CH.CHCl.CH_3$. (91°). S.G. $\frac{0}{}$ ·88. From $(CH_3)_2CH.CH:CH_2$ and HCl (Berthelot, *C. R.* 56, 700; Wurtz, *A.* 129, 368; Wyschnegradsky, *A.* 190, 357).

***s-Sec*-amyl chloride** Et_2CHCl. (103°–105°). S.G. $\frac{21}{}$ ·895. From the alcohol (W. a. S.).

***Tert*-amyl chloride** $EtCMe_2Cl$. (86°). S.G. $\frac{19}{}$ ·870. By action of PCl_5 on tert-amyl alcohol or on methyl-isopropyl-carbinol (Wyschnegradsky, *A.* 190, 336; 191, 331).

AMYL-CHLORO- *v.* CHLORO-AMYL.

***Iso* - AMYL CYANATE** $C_6H_{11}NO$ *i.e.* $C_5H_{11}N.CO$. (135°). Prepared by distilling amyl-carbamic ether with P_2O_5 (Custer, *B.* 12, 1330), or from $C_5H_{11}SO_4K$ and potassium cyanate (Wurtz, *A. Ch.* [3] 42, 43). With *ammonia* it yields amyl-urea, and with *potash* it yields amylamine.

AMYL CYANIDE *v.* AMYL CARBAMINE and nitrile of HEXOIC ACID.

AMYLENE C_5H_{10}. *Pentene.* Mol. w. 70.

***n*-Propyl-ethylene** $CH_3.CH_2.CH_2.CH:CH_2$. (40°).

Formation.—1. Together with amyl acetate when KOAc and Ac_2O act on *n*-amyl chloride at 200° (Schorlemmer, *A.* 161, 269).—2. Together with di-allyl (principal product), pentane, and other bodies, in the action of zinc ethide on allyl iodide (Wurtz, *A.* 123, 203; 127, 55; 148, 131).

Properties.—Liquid; insol. H_2SO_4 (2 vols.) diluted with water (1 vol.).

Reactions.—1. Gives Pr.CHI.Me with HI.—2. Alkaline $KMnO_4$ gives succinic, butyric, oxalic, and formic acids (Zeidler, *A.* 197. 253).

Isopropyl-ethylene $(CH_3)_2.CH.CH:CH_2$. (21°). Formed together with $EtCMe:CH_2$ by action of alcoholic KOH on isoamyl iodide (Wyschnegradsky, *B.* 10, 81; *A.* 190, 328).

Properties.—Liquid; insol. at 0° in H_2SO_4 (2 vols.) mixed with water (1 vol.).

Reactions.—Does not combine with HI at −20°, but at 20° it combines slowly forming $(CH_3)_2CH.CHI.CH_3$.

***s*-Methyl-ethyl-ethylene** $CH_3.CH:CH.Et$. (36°).

Formation.—1. From $CH_3.CH_2.CHI.CH_2.CH_3$ (Wagner a. Saytzeff, *A.* 175, 373; 179, 302), or $CH_3.CHI.CH_2.CH_2.CH_3$ (Wurtz), and an alcoholic solution of KOH.—2. From ethyl-crotonic acid, $CH_3.CH:CEt.CO_2H$, by combining it with HBr and neutralising the resulting β-bromo-di-ethyl-acetic acid: $CH_3.CHBr.CEtH.CO_2Na = NaBr + CO_2 + CH_3.CH:CEtH$ (Fittig, *A.* 200, 27).

Reaction.—HI forms $CH_3.CHI.CH_2.CH_2.CH_3$.

***u*-Methyl-ethyl-ethylene** $Et.C(CH_3):CH_2$. (32°). S.G. $\frac{0}{}$ ·670. From active amyl iodide and alcoholic KOH (Le Bel, *Bl.* [2] 25, 546).

Properties.—Liquid; dissolves in H_2SO_4 (2 vols.) diluted with water (1 vol.).

Reactions.—HI forms $CH_3.CH_2.CI(CH_3).CH_3$.

Tri-methyl-ethylene $(CH_3)_2C:CH.CH_3$. (36°). S.G. $\frac{15}{15}$ ·6704; $\frac{25}{25}$ ·6614. M.M. 6·121 at 13·2° (Perkin, *C. J.* 45, 448).

Formation.—1. From $CH_3.CH_2.CI(CH_3)_2$ (Ermolajeff, *Z.* [2] 6, 275) or $CH_3.CHI.CH(CH_3)_2$ (Wy.) and alcoholic KOH.—2. From ethyl isoamyl oxide and P_2O_5 (Flavitzky, *A.* 169, 206).

Properties.—Liquid; soluble at 0° in H_2SO_4 (2 vols.) diluted with water (1 vol.)

Reaction.—HI forms $(CH_3)_2CI.CH_2.CH_3$.

Iso-amylene. (36°). S.G. $\frac{9·9}{4}$ ·661; $\frac{20}{4}$ ·648. H.F.p. 10,600 (Berthelot); 18,970 (*Th.*). H.F.v. 16,650 (*Th.*). V.D. 2·47 (for 2·42). S.V. 110 (R. Schiff, *A.* 220, 89); 110·8 (Ramsay). μ_β 1·3813. R_∞ 39·29 (Brühl). A mixture of tri-methyl-ethylene (90 p.c.) and *u*-methyl-ethyl ethylene (10 p.c.) with a small quantity of isopropyl-ethylene (Flavitzky, *A.* 179, 340).

Preparation.—From isoamyl alcohol and $ZnCl_2$, many other hydrocarbons being also formed (Etard, *C. R.* 86, 488; Wyschnegradsky, *C. R.* 86, 973).

Properties.—Absorbed at 0° by H_2SO_4 (2 vols.) diluted with water (1 vol.), with production of tertiary amyl alcohol. A more dilute acid (2 pts. H_2SO_4 to 1 pt. water by weight) forms methyl-isopropyl-carbinol (Ossipoff, *B.* 8, 542, 1240).—NOCl forms a compound $C_5H_{10}NOCl$ which may be reduced to amylamine (Tönnies, *B.* 12, 169).—3. $C_5H_{10}K_2PtCl_4aq$ is formed by boiling isoamyl alcohol with $PtCl_4$ and then adding KCl (Birnbaum, *A.* 145, 73); deliquescent plates.

Other References.—Balard, *A. Ch.* [3] 12, 320; Frankland, *C. J.* 3, 35; Bauer, *Sitz. B.* 44 [2] 87; *Z.* 1866, 380, 667; Bauer a. Klein, *Z.* [2] 4, 386; Guthrie, *A.* 121, 108; Lippmann, *A.* 129, 81; *M.* 5, 559; Eltekoff, *B.* 6, 1258; Linnemann, *A.* 143, 350; Buff, *A. Suppl.* 4, 143; 148, 349; Thorpe a. Young, *A.* 165, 7; Flavitzky, *A.* 165, 157; Le Bel, *Bl.* 17, 3; 18, 166; Berthelot, *A. Ch.* [4] 9, 442; *C. R.* 44, 1350; Renard, *A. Ch.* [6] 1, 227; Markownikoff, *Z.* [2] 2, 502.

Oxidation of amylenes.—Examined by Zeidler, *A.* 186, 245; 197, 253; Truchot, *C. R.* 63, 274; Berthelot, *C. R.* 64, 36.

Di-amylene $C_{10}H_{20}$. (156°). S.G. $\frac{10}{4}$ ·780. R_{∞} 76·58 (Nasini a. Bernheimer, *G.* 15, 93). S.V. 211·18. Occurs in the product of action of $ZnCl_2$, H_2SO_4, or P_2O_5, on isoamyl alcohol; and is also formed by shaking amylene with H_2SO_4.

Reactions.—1. *Bromine* forms $C_{10}H_{20}Br_2$.—2. *Chromic acid mixture* produces *amethenic acid* $C_7H_{14}O_2$ (Schneider, *A.* 157, 213; Pawlow, *J. R.* 9, 75).

Combinations.—$C_{10}H_{20}S_2Cl_2$; from amylene and S_2Cl_2 (Guthrie, *C. J.* 12, 112; 13, 35; 14, 128). Distilled over KOH it forms $C_{10}H_{18}S_2$, (112°), S.G. ^{13} ·880. $ZnEt_2$ gives $C_{14}H_{30}S_2$ (240°-250°).

References.—Balard, *A. Ch.* [3] 12, 320; Bauer, *Bl.* 1863, 332; 1867, 341; Berthelot, *C. R.* 56, 1242; Walz, *Z.* [2] 4, 315; W. v. Schneider, *A.* 157, 185; Wyschnegradsky, *B.* 8, 434; Lebedeff, *J. R.* 7, 246; Tugolessoff, *B.* 12, 1486.

Triamylene $C_{15}H_{30}$. (248°). S.G. ·81. V.D. 7·6 (for 7·4). Among products of action of $ZnCl_2$ on isoamyl alcohol (Bauer, *Sitz. B.* 44 [2] 87; *A.* 137, 249; 147, 254). Forms a bromide, $C_{15}H_{30}Br_2$, converted by alcoholic KOH into benylene, $C_{15}H_{28}$, (223°-228°).

Tetra-amylene $C_{20}H_{40}$. (390°-400°). S.G. ^{0} ·871. Among products of action of $ZnCl_2$ on isoamyl alcohol (Balard; Bauer).

AMYLENE DI-ACETIN *v. di*-OXY-PENTANE.

AMYLENE BENZOATE *v. di*-OXY-PENTANE.

AMYLENE BROMIDE *v. di*-BROMO-PROPANE.

AMYLENE TRI-CARBOXYLIC ACID $C_8H_{10}O_6$ *i.e.* $CH_2{:}CH.CH_2.C(CO_2H)_2.CH_2.CO_2H$.

Ether.—Et_3A'''. [151°]. Obtained by introducing allyl into ethane tri-carboxylic acid (Hjelt, *B.* 16, 333). At 160° it splits up into CO_2 and allyl-succinic acid (*q. v.*).

AMYLENE CHLORHYDRIN *v.* CHLORO-AMYL ALCOHOL.

AMYLENE CHLORIDE *v. di*-CHLORO-PENTANE.

AMYLENE - CHLORO - SULPHIDE *v. di*-AMYLENE, *Combinations.*

AMYLENE IS-ETHIONIC ACID *v.* OXY-PENTANE SULPHONIC ACID.

AMYLENE GLYCOL *v. di*-OXY-PENTANE.

AMYLENE GUANAMINE $C_8H_{15}N_5$. [178°]. Formed by heating guanidine caproate (hexoate) at 225° (Bandrowski, *B.* 9, 243). Crystals; v. sl. sol. water, v. sol. alcohol. Salt.—B'HCl.

AMYLENE HYDRATE. Tertiary AMYL ALCOHOL (*q. v.*).

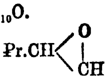
AMYLENE HYDRIDE. PENTANE (*q. v.*).

AMYLENE HYDROCHLORIDE. AMYL CHLORIDE (*q. v.*).

AMYLENE NITRITE $C_5H_{10}N_2O_4$ *i.e.* $C_5H_{10}(NO_2)_2$. From amylene by treatment with NO_2 or fuming HNO_3 (Guthrie, *C. J.* 13, 45, 129). Tables; decomposed at 95°.

AMYLENE OXIDE $C_5H_{10}O$.

Isopropyl-ethylene oxide



$\mathrm{Pr.CH}<\begin{matrix}\mathrm{O}\\ |\\ \mathrm{CH_2}\end{matrix}$

(82°). By action of potash on chloro-amyl alcohol, $Pr.CHCl.CH_2OH$ or $PrCH(OH).CH_2Cl$ (Eltekoff, *Bl.* [2] 40, 23; *J. R.* 14, 355). Heated with water for 50 hours at 100° it forms $Pr.CH(OH).CH_2OH$. Does not combine with $NaHSO_3$.

Tri-methyl-ethylene oxide

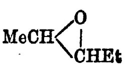
$\mathrm{Me_2C}<\begin{matrix}\mathrm{O}\\ |\\ \mathrm{CHMe}\end{matrix}$

(76°). S.G. ^{0} ·829.

Preparation.—By action of potash on the chloro-amyl alcohol obtained by the union of $Me_2C{:}CHMe$ with HClO (E.).

Properties. — Liquid; readily units with cold water to form di-oxy-pentane. Does not combine with $NaHSO_3$.

Methyl-ethyl-ethylene oxide



$\mathrm{MeCH}<\begin{matrix}\mathrm{O}\\ |\\ \mathrm{CHEt}\end{matrix}$

(80°). Prepared by action of potash on the chloro-amyl alcohol resulting from union of $Me.CH{:}CHEt$ with HClO (E.). Unites at 100° with water forming $MeCH(OH).CHEt(OH)$.

Di-amylene oxide $C_{10}H_{20}O$. (170°-180°). From di-acetyl-di-OXY-DECANE (*q. v.*) (di-amylene diacetin) and solid KOH (Bauer, *Sitz. B.* 45, 276) Oil. Reduces ammoniacal $AgNO_3$.

Di-amylene oxide (198°-203°). V.D. 5·3 (for 5·4). Obtained as an oil by the action of potash on a mixture of amylene and Bz_2O_2 that has been heated at 110° (Lippmann, *M.* 5, 562). Does not reduce ammoniacal $AgNO_3$ or combine with $NaHSO_3$.

Di-amylene oxide (180°-190°). From di-amylene and chromic mixture (Schneider, *A.* 157, 221). Reduces ammoniacal $AgNO_3$. Oxidised to amethenic acid, $C_7H_{14}O_2$.

Di-amylene oxide (193°). From di-amylene bromide (*v. di*-BROMO-DECANE), water, and PbO (Eltekoff, *J.* 1878, 374).

Two or more of the preceding di-amylene oxides may be identical.

AMYLENE SULPHIDE $C_5H_{10}S$. (c. 200°). S.G. ^{13} ·907. Formed by boiling $C_{10}H_{20}S_2Cl_2$ (*v.* DIAMYLENE) with zinc (Guthrie, *C. J.* 14, 128). Colourless oil.

Amylene sulphide (?) $C_5H_{10}S$. (130°-150°). V.D. 3·2 (calc. 3·5). Formed by action of acids or of heat upon the product of the union of $ZnEt_2$ and CS_2 (Grabowsky, *A.* 138, 165). Alcoholic $HgCl_2$ forms plates of $C_5H_{10}S\,HgS\,HgCl_2$; alcoholic $AgNO_3$ forms $C_5H_{10}OAg_2OAgNO_3$.

AMYL ENNONYL KETONE (?) $C_{15}H_{24}O$ *i.e.* $Et_2CH.CO.C_3H_4(C_2H_3)_2$ (?). (280°-300°). One of the products got by passing CO over a mixture of NaOEt and NaOAc at 250° (Geuther a. Fröhlich, *A.* 202, 312).

AMYL ENNYL KETONE $C_{14}H_{28}O$ *i.e.* $C_4H_9.CO.C_9H_{19}$ (?). *Amyl - valerone.* (209°). S.G. ^{12} ·845. One of the products of the passage of CO over sodium iso-amylate at 100° (Geuther a. Fröhlich, *A.* 202, 301). Liquid; smells like quinces. Does not combine with $NaHSO_3$.

AMYL ETHER *v.* AMYL OXIDE.

AMYL FLUORIDE ×$C_5H_{11}F$. (72°-92°). A mixture of amyl fluoride and polymerides of amylene is formed by saturating amylene at 0° with HF (S. Young, *C. J.* 39, 489).

AMYL-GLYOXALINE $C_8H_{14}N_2$ *i.e.*

$\mathrm{CH}\lessdot\begin{matrix}\mathrm{NH}\\ \mathrm{CH.N}\end{matrix}\gtrdot\mathrm{C.C_5H_{11}}$ (?). *Glyoxal-œnanthyline.*

[84°]. From œnanthol-ammonia and glyoxal (Radziszewski, *B.* 16, 748). Thin glistening needles. Sol. alcohol, sl. sol. ether, insol. water.

***Iso*-amyl-glyoxaline** $C_8H_{14}N_2$ *i.e.*

$CH{<}\begin{matrix}N(C_5H_{11})\\CH-N\end{matrix}{>}CH$ (?). (240°–245°).

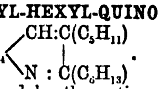
S.G. ^{18} ·94. From glyoxaline and amyl bromide (Wallach, *A.* 214, 322; *B.* 15, 651). Liquid; v. sl. sol. water, sol. even in very dilute alcohol.

Salt.—$B'_2H_2PtCl_6$: plates (from alcoholic HCl); v. sl. sol. cold water or cold alcohol.

***Iso*-AMYL HEPTYL OXIDE** $C_{12}H_{26}O$ *i.e.* $C_5H_{11}.O.C_7H_{15}$. *Amyl-œnanthyl ether.* (221°). S.G. ^{20} ·668. V.D. 6·57 (calc. 6·45). From sodium heptylate and isoamyl iodide (Wills, *C. J.* 6, 316).

(*Py.* 2:3)-AMYL-HEXYL-QUINOLINE

$C_{20}H_{29}N$ *i.e.*



$C_6H_4\left\langle\begin{matrix}CH:C(C_5H_{11})\\ \vert \\ N:C(C_6H_{13})\end{matrix}\right.$. (320°–360°).

Oily fluid. Formed by the action of œnanthic aldehyde and HCl upon aniline (Doebner a. Miller, *B.* 17, 1719).

Salts.—$B'_2H_2Cl_2PtCl_4$: large yellow plates. —$B'C_6H_2(NO_2)_3OH$: yellow needles; sl. sol. water and cold alcohol.

AMYL HYDRIDE *v.* PENTANE.

***Iso*-AMYL-HYDRO-ANTHRANOL** $C_{19}H_{22}O$ or

$C_6H_4{<}\begin{matrix}C(C_5H_{11})(OH)\\CH_2\text{———————}\end{matrix}{>}C_6H_4$. [74°]. Formed, as a by-product in the treatment of anthraquinone with zinc-dust and amyl bromide (Liebermann a. Tobias, *B.* 14, 801; *A.* 212, 102). Crystalline solid. Insoluble in water, extremely soluble in other solvents. On boiling with alcoholic HCl it gives amyl-anthracene.

***Iso*-AMYL-HYDROQUINONE.** From isoamyl-arbutin and dilute H_2SO_4, glucose being also formed (Schiff a. Pellizzari, *A.* 221, 365). Needles. Gives a crystalline nitro-derivative.

AMYLIDENE-ACETO-ACETIC ETHER *v.* p. 24.

***Iso*-AMYLIDENE-*m*-AMIDO-BENZOIC ACID** $C_{12}H_{15}NO_2$ *i.e.* C_4H_9 $CH:N.C_6H_4.CO_2H$. [c. 130°]. From valeric aldehyde and *m*-amido-benzoic acid (Schiff, *A.* 210, 119).

AMYLIDENE ANILINE $C_{11}H_{15}N$ *i.e.* $Me_2CH.CH_2.CH:NPh$. [97°]. From valeric aldehyde and aniline in the cold (Lippmann a. Strecker, *B.* 12, 74). Prisms. — $B'HCl$. — $B'_2H_2PtCl_6$. Valeric aldehyde and aniline at 100° form di-amylidene-di-phenyl-diamine, a neutral oil, $C_{22}H_{30}N_2$ (Schiff, *B.* 12, 298).

AMYLIDENE BIURET $C_7H_{13}N_3O_2$. From valeric aldehyde and cyanic acid (Baeyer, *A.* 114, 164).

AMYLIDENE BROMIDE *v. di*-BROMO-PENTANE.

AMYLIDENE-DI-CARBAMIC ETHER $C_{11}H_{22}N_2O_4$ *i.e.* $Me_2CH.CH_2.CH(NH.CO_2Et)_2$. *Amylidene urethane.* [126°] From carbamic ether, valeric aldehyde, and conc. HCl (Bischoff, *B.* 7, 633). Needles. Split up by hot dilute acids into valeric aldehyde and carbamic ether.

AMYLIDENE CHLORIDE *v. di*-CHLORO-PENTANE.

α **AMYLIDENE GLYCOL** *v. ortho*-VALERIC ALDEHYDE.

AMYL IODIDES $C_5H_{11}I$. Mol. w. 198.

***n*-Amyl iodide** $CH_3.CH_2.CH_2.CH_2.CH_2I$. (156° cor.) S.G. ^{0} 1·544; ^{20} 1·517. From the chloride and HI (Lieben a. Rossi, *A.* 159, 74).

***Iso*-amyl iodide.** (148°). S.G. $\frac{15}{15}$ 1·510; $\frac{25}{25}$ 1·498. M.M. 13·20 at 19·6° (Perkin, *C. J.* 45, 462). S.V. 151·08 (R. Schiff, *B.* 19, 564). From isoamyl alcohol (4 pts.), iodine (5 pts.), and P (Cahours, *A. Ch.* [2] 70, 81; Grimm, *J. pr.* 62, 385). From amyl-chloride and $CaI_2 8\frac{1}{2}aq$ at 100° (Van Romburgh, *R.* 1, 151). Partially converted by heating with EtOH into EtI and isoamyl alcohol (Friedel a. Crafts, *A.* 130, 198).

Active amyl iodide $EtCHMe.CH_2I$. (144°–145°). S.G. $\frac{16}{16}$ 1·5425 (Just, *A.* 220, 152). α = 3·76° for 100 mm. at 16° (J.); 5·2° (Le Bel, *Bl.* [2] 25, 542). From the alcohol by HI. Reduced in alcoholic solution by Sn and conc. HCl. to inactive isopentane (J.)

u-n-Sec-**amyl iodide** $CH_3.CH_2.CH_2.CHI.CH_3$. (144°–145°). S.G. ^{0} 1·539. Formed by union of HI with $CH_3.CH_2.CH_2CH:CH_2$ (Wagner a. Saytzeff, *A.* 179, 313; Wyschnegradsky, *A.* 190, 347) or $CH_3.CH_2.CH:CH.CH_3$ (Wurtz, *A.* 148, 132).

Iso-sec-**amyl iodide** $(CH_3)_2CH.CHI.CH_3$. (137°–139°). From $(CH_3)_2CH.CH:CH_2$ and HI (Wy.). Water and PbO convert it into $(CH_3)_2C(OH).CH_2.CH_3$.

s-n-Sec-**amyl iodide** $CH_3.CH_2.CHI.CH_2.CH_3$. (145°–146°). S.G. ^{0} 1·528; ^{20} 1·50. From diethyl-carbinol and HI (W. a. S.).

Tert-**amyl iodide** $(CH_3)_2.CI.CH_2.CH_3$. (129°). S.G. ^{0} 1·524; ^{19} 1·50. From *iso-sec*-amyl iodide and HI (Winogradoff, *A.* 191, 132); also from *tert*-amyl alcohol and HI (Wy.). By shaking with water for $1\frac{1}{2}$ hours it is almost completely converted into *tert*-amyl alcohol (Bauer, *A.* 220, 158). With MeOH at 100° it forms MeI and *tert*-amyl alcohol; MeOAc at 110° gives amylene, MeI, and HOAc.

DI-*n*-AMYL KETONE $C_{11}H_{22}O$ *i.e.* $(C_5H_{11})_2CO$. *Caprone.* [15°]. (226° cor.). S.G. ^{20} ·826. Prepared by distilling calcic caproate. Does not combine with $NaHSO_3$.

Reactions.—1. Conc. HNO_3 forms caproic nitro-valeric, and oxalic acids.—2. CrO_3 forms caproic and valeric acids (E. Schmidt, *B.* 5, 601; Lieben a. Janecek, *A.* 187, 134; Hercz, *A.* 186, 263).

***n*-AMYL-MALONIC ACID** $C_8H_{14}O_4$ *i.e.* $(C_5H_{11})CH(CO_2H)_2$. [82°]. Formed by saponifying the product of the action of KCy upon α-bromo-heptoic ether (Hell a. Schüle, *B.* 18, 626). Split up at 140° into CO_2 and *n*-hexoic acid.

Salts.—CaA″: S. ·04 at 18°.—SrA″: S. ·09 at 16°.—BaA″: S. ·6 at 10°.—CdA″.—PbA″: S. ·008 at 20°.—Ag_2A''.

TRI-*Iso*-AMYL-MELAMINE $C_{18}H_{36}N_6$ *i.e.* $C_3H_3(C_5H_{11})_3N_6$. Formed by desulphuration of isoamyl thiocarbimide (Hofmann, *B.* 3, 264). Thick oil.—$B''H_2PtCl_6$.

***Iso*-AMYL MERCAPTAN** $C_5H_{12}S$ *i.e.* $C_5H_{11}SH$. Mol. w. 104. (120° i.V.) (Beckmann); (118°) (Nasini, *G.* 1883, 302). S.G. $\frac{20}{4}$ ·8348. R_∞ 31·94 (N.). From isoamyl chloride and KHS (Balard, *A.* 52, 313) or $C_5H_{11}SO_4K$ (Krutzsch, *J. pr.* 31, 1).

AMYL MUSTARD OIL *v.* AMYL THIOCARBIMIDE.

AMYL-NAPHTHALENES $C_{15}H_{18}$.

(α)-***Iso*-amyl-naphthalene** $C_{10}H_7.C_5H_{11}$ [1]. Formed by heating an ethereal solution of (α)-bromo-naphthalene and isoamyl bromide with Na (Leone, *G.* 12, 209).—**Picrate**, [85°–90°]: pale yellow needles.

(β)-*Iso*-amyl-naphthalene $C_{10}H_7.C_5H_{11}$ [2]. (c. 290°). From naphthalene, isoamyl chloride, and $AlCl_3$ (Roux, *Bl.* [2] 41, 379).—*Picrate* $C_{15}H_{18}C_6H_2(NO_2)_3OH$. [105°-110°].

Amyl-naphthalene (?). (305°). From lapachic acid, HI and P (Paterno, *G.* 12, 369).—*Picrate* [141°]: orange needles.

Iso-**AMYL NITRATE** $C_5H_{11}NO_3$. Mol. w. 133. (147°). S.V. 153·59 (R. Schiff, *B.* 19, 567). From urea nitrate (10 g.), isoamyl alcohol (40 g.) and HNO_3 (30 g.) (P. W. Hofmann, *A. Ch.* [3] 23, 374). Liquid, smelling like bugs.

Iso-**AMYL NITRITE** $C_5H_{11}NO_2$. Mol. w. 117. (96°) (B.). (99°) (Guthrie, *A.* 111, 82). S.G. ·9. H.F.p. 48,140. H.F.v. 44,660 (*Th.*).

Preparation. — 1. Nitrous vapours (from As_2O_3 and HNO_3 of S.G. 1·52) are passed into isoamyl alcohol (Balard, *A. Ch.* [3] 12, 318; Hilger, *Ar. Ph.* [3] 4, 485; Williams a. Smith, *Ph.* [3] 16, 409). — 2. By distilling together KNO_2, isoamyl alcohol, and dilute H_2SO_4 (Rennard, *Russ. Zeitschr. Pharm.* 1874, 1). Yellowish liquid, smelling like nitrous ether.

AMYLNITROUS ACID, so-called. $C_5H_{10}N_2O_4$. Obtained by action of HNO_3 on di-amyl ketone (Chancel, *C. R.* 94, 399). Liquid; may be reduced to *n*-valeric acid.

Salt.—$C_5H_9KN_2O_4$: greasy-looking plates.

AMYLODEXTRIN *v.* DEXTRIN.

AMYLOID *v.* STARCH.

AMYLONITROPHOSPHOROUS ACID, so-called. $C_{10}H_{23}PNO_4$ (?). An oil, got by action of P_2O_5 on isoamyl nitrite (Guthrie, *A.* 111, 85).

AMYL OXALATE *v.* OXALIC ACID.

Iso-**AMYL OXAMIDE** $C_7H_{14}N_2O_2$ *i.e.* $NH_2.CO.CO.NHC_5H_{11}$. [181°]. From isobutyl-isoamyl glyoxaline and H_2O_2 (Radziszewsky a. Szul, *B.* 17, 1296).

Di-*iso*-amyl oxamide $C_{12}H_{24}N_2O_2$ *i.e.* $C_5H_{11}.NH.CO.CO.NHC_5H_{11}$. [129°] (Wallach a. Schulze, *B.* 13, 516). [139°] (Wurtz). Silky needles; insol. water. From isoamylamine and ethyl oxalate.

AMYL-OXANTHRANOL *v.* OXANTHRANOL.

AMYL OXIDE $C_{10}H_{22}O$. *Amyl ether.* M.w. 158.

Iso-**amyl oxide** $(C_5H_{11})_2O$. (173°). S.G. $\frac{15}{15}$ ·7807; $\frac{25}{25}$ ·7741. M.M. 11·168 at 15·6° (Perkin, *C. J.* 45, 474). From potassium isoamylate and amyl iodide.

Iso-sec-**amyl oxide** (Pr.CMeH)$_2$O. (163°). From Pr.CMeHI and Ag_2O (Wurtz, *A.* 129, 366).

Iso-**AMYL-PHENOL** $C_{11}H_{16}O$ *i.e.* $C_5H_{11}.C_6H_4.OH$ [1:4]. [93°]. (250°). Formed by heating phenol with isoamyl alcohol and $ZnCl_2$ at 180° (Liebmann, *B.* 15, 151) or by the action of nitrous acid upon amido-phenyl-isopentane (Calm, *B.* 15, 1646). Long needles; sl. sol. water.

Benzoyl derivative $C_{10}H_{15}OBz$. [81°]. (349° cor.). Flat needles, formed by distilling tri-isoamyl phosphate with NaOBz (Kreysler, *B.* 18, 1717).

AMYL-PHENYL- *v.* PHENYL-AMYL-.

Iso-**AMYL-PHENYL PHOSPHATE** $C_{33}H_{45}PO_4$ *i.e.* $(C_5H_{11}.C_6H_4.O)_3PO$. (above 400°). Formed by heating isoamyl-phenol with $POCl_3$ (Kreysler, *B.* 18, 1701). Thick oil; v. sol. ether, sol. alcohol.

Iso-**AMYL-PHENYL SILICATE** $C_{44}H_{60}SiO_4$ *i.e.* $(C_5H_{11}.C_6H_4.O)_4Si$. (c. 394°) at 118 mm. From isoamyl-phenol and $SiCl_4$ (Hertkorn, *B.* 18, 1692).

AMYL PHOSPHATES.

Iso-**amyl-phosphoric acid** $(C_5H_{11}O).PO(OH)_2$. From syrupy phosphoric acid and amyl alcohol at ordinary temperature (Guthrie, *C. J.* 9, 134). Deliquescent crystalline mass; v. sol. water, and alcohol, insol. ether. Salts.—K_2A''.—$(NH_4)_2A''$.—BaA″.—PbA″.—CuA″.—Ag_2A''.

Di-*iso*-amyl-phosphoric acid $(C_5H_{11}O)_2PO(OH)$. From amyl alcohol and bromide of phosphorus (Kraut, *A.* 118, 102). Salts.—CaA'_2: S. 1·6 at 18°.—AgA′.—$AgHA'_2$.

AMYL-PHOSPHINES *v.* PHOSPHINES (Hofmann, *B.* 6, 297).

Iso-**amyl phosphine** $C_5H_{11}PH_2$. (107°).

Di-*iso*-amyl phosphine $(C_5H_{11})_2PH$. (c. 213°).

Tri-*iso*-amyl phosphine $(C_5H_{11})_3P$. (300°).

Oxide $(C_5H_{11})_3PO$. [c. 65°].

Iso-amylo-iodide $(C_5H_{11})_4PI$.

Iso-**AMYL PHOSPHINIC ACID** $C_5H_{13}PO_3$ *i.e.* $C_5H_{11}.PO(OH)_2$. *Pentane phosphinic acid.* [160°]. From isoamyl phosphine and HNO_3 (S.G. 1·35). Pearly plates (from water).

Salt.—Ag_2A'': amorphous pp. (Hofmann, *B.* 6, 305).

AMYL PHOSPHITES.

Iso-**amyl phosphorous acid** $(C_5H_{11}O)P(OH)_2$. Formed together with di-isoamyl-phosphorous acid by shaking with water the product of the action of PCl_3 on isoamyl alcohol. Dilute Na_2CO_3 dissolves mono- but not di-, amyl phosphite (Wurtz, *A. Ch.* [3] 16, 227).

Chloride $C_5H_{11}O.PCl_2$. (173°). S.G. ^{0} 1·109 (Menschutkin, *A.* 139, 348).

Di-*iso*-amyl-phosphorous acid $(C_5H_{11}O)_2P(OH)$. S.G. $\underline{19}$ ·97.

Tri-*iso*-amyl phosphite $(C_5H_{11}O)_3P$. (236°), in hydrogen. From PCl_3 and $NaOC_5H_{11}$ (Williamson a. Railton, *C. J.* 7, 218).

AMYL-PIPERIDINE $C_{10}H_{21}N$ *i.e.* $C_5H_{10}N(C_5H_{11})$. (188°). Colourless liquid, nearly insoluble in water. Formed by digesting piperidine with amyl bromide and aqueous KOH.

Methylo-iodide. B′MeI. [195°]. Thick prisms. By moist Ag_2O it gives an alkaline hydrate which on dry-distillation yields methyl-amyl-piperidine (Schotten, *B.* 15, 421).

Iso-**AMYL-PYRROL** $C_9H_{15}N$ *i.e.* $C_5H_{11}NC_4H_4$ (c. 182°). S.G. $\underline{10}$ ·879. Formed by distilling isoamylamine mucate (C. A. Bell, *B.* 10, 1866).

Iso-**amyl-pyrrol carboxylic acid**, *isoamylamide* $C_5H_{11}.NC_4H_3.CO.NHC_5H_{11}$. [77°]. Prisms. Formed along with the isoamyl-pyrrol (*B.*).

Iso-**AMYL SILICATE** $C_{20}H_{44}SiO_4$ *i.e.* $Si(C_5H_{11}O)_4$. (324°). S.G. $\underline{20}$ ·868. V.D. 15·2 (calc. 13·0). From $SiCl_4$ and isoamyl alcohol (Ebelmen, *A.* 57, 331). Oil, very slowly decomposed by water.

AMYL SULPHATES.

Iso-**amyl sulphuric acid** $C_5H_{12}SO_4$ *i.e.* $C_5H_{11}SO_4H$ (Cahours, *A. Ch.* [2] 70, 86; Kekulé, *A.* 75, 275).

Salts. — NH_4A'.—NaA′ 1½aq. — KA′ ½aq.— MgA'_2 4aq.— CaA'_2 2aq.— SrA'_2 2aq.— BaA'_2 2aq: flat tables, S. 9·7 at 10° (Balbiano, *B.* 9, 1437); S.G. 1·623 at 21·2° (Clarke, *B.* 11, 1506).— ZnA'_2 2aq.— HgA'_2 2aq.— PbA'_2 aq.— MnA'_2 4aq.— NiA'_2 2aq.— CuA'_2 4aq.—AgA′.

Iso-**amyl sulphate** $(C_5H_{11})_2SO_4$. Formed by passing SO_2 into warm amyl nitrite (Chapman, *B.* 8, 920).

AMYL SULPHIDES.

Di-*iso*-amyl-sulphide $(C_5H_{11})_2S$. Mol. w. 174. (214° i.V.). S.G. $\frac{20}{4}$ ·8431. R∞ 54·2 (Nasini, *G.* 13, 302). Amyl alcohol (131°–132°) is converted by PCl_5 into amyl chloride and this is mixed with alcoholic K_2S (from half saturation of alcoholic KOH with H_2S) and heated in closed vessels for 10 hours at 100°. Product fractionated (Beckmann, *J. pr.* [2] 17, 440). Also from potassium amyl-sulphate and K_2S (Balard, *A. Ch.* [3] 12, 303).

Di-*iso*-amyl disulphide $(C_5H_{11})_2S_2$. (250°). S.G. ^{12} ·918. From potassium amyl-sulphate and K_2S_2 (O. Henry, *A. Ch.* [3] 25, 246; Spring a. Legros, *B.* 15, 1938).

Iso-**AMYL SULPHITE** $(C_5H_{11}O)_2SO$. (230°–250°). From $SOCl_2$ or S_2Cl_2 and isoamyl alcohol (Carius, *A.* 106, 291; 111, 97). Oil; decomposed by water or KOHAq into amyl-sulphurous acid and amyl alcohol.

AMYL SULPHOCYANIDE $C_6H_{11}NS$ *i.e.* $C_5H_{11}S.CN$. (197°). S.G. ^{20} ·905. Got by distilling potassium amyl-sulphate with potassium sulphocyanide (Henry, *A. Ch.* [3] 25, 248; Medlock, *A.* 69, 214).

Di-*iso*-AMYL SULPHONE $(C_5H_{11})_2SO_2$. [31°]. (295°). Di-iso-amyl sulphoxide (5 pts.) is heated with water (20 pts.) till it melts, a solution of $KMnO_4$ (3 pts.) in hot water (30 pts.) is added with constant agitation. The sulphone is extracted with ether. The yield is that indicated by theory (Beckmann, *J. pr.* [2] 17, 411).

Properties.—Long needles, grouped in tufts. Sl. sol. hot water; sol. alcohol, ether, benzene, $CHCl_3$ and CS_2. Soluble in H_2SO_4, HNO_3 and acetic acid, but precipitated by water from these solutions. Not reduced by Zn and H_2SO_4, by sodium-amalgam or by HI.

AMYL-SULPHONIC ACID *v.* PENTANE SULPHONIC ACID.

DI-*iso*-AMYL-SULPHOXIDE $(C_5H_{11})_2SO$. [37°]. From di-amyl sulphide (1 pt.) and fuming HNO_3 (2 pts.). Crystallised from ether (Saytzeff, *A.* 139, 354; Beckmann, *J. pr.* [2] 17, 441). Flexible fatty-looking crystals. Chlorine acts on it in presence of water forming pentane sulphonic acid, chloro-pentane sulphonic acid, di-isoamyl sulphone, valeric acid, chloro-valeric acid, tri- and tetra-chloro-pentanes, &c. (Spring a. Winssinger, *Bl.* [2] 41, 307).

AMYL-SULPHURIC ACID *v.* AMYL SULPHATE.

Iso-**AMYL TELLURIDE** $Te(C_5H_{11})_2$. (c. 198°). Got, in impure state, by distilling calcium amyl sulphate with TeK_2 (Wöhler a. Dean, *A.* 97, 1).

Iso-**AMYL-DI-THIO-CARBAMIC ACID** $C_6H_{13}NS_2$ *i.e.* $C_5H_{11}NH.CS.SH$. *Isoamylamine salt* $C_5H_{11}NH_2HA'$. From isoamylamine and CS_2 in ethereal solution (Hofmann, *J.* 1859, 379). Laminæ.

AMYL THIOCARBIMIDES $C_6H_{11}NS$ *i.e.* $C_5H_{11}N.CS$. *Amyl mustard oils.* Mol. w. 129.

Iso-**amyl-thio-carbimide** (183°). S.G. ^{17} ·942. Obtained by boiling the preceding compound with aqueous $HgCl_2$ (Hofmann, *B.* 1, 173; Buff, *B.* 1, 206).

Tert-**amyl thio-carbimide** $EtCMe_2N.CS$. (166°). From $EtCMe_2NH_2$ by successive treatment with CS_2 and $HgCl_2$ (Rudneff, *Bl.* [2] 33, 300).

AMYL THIO-PHOSPHATES.

Iso-**amyl thio-phosphate** $(C_5H_{11})H_2PSO_3$. From isoamyl alcohol and $PSCl_3$ (Chevrier, *Z.* 1869, 413).

Tri-*iso*-amyl thiophosphate $(C_5H_{11})_3PSO_3$. S.G. ^{12} ·85. From $C_5H_{11}ONa$ and $PSCl_3$ (C.). Oil.

Di-*iso*-amyl di-thio-phosphate $(C_5H_{11})_2HPS_2O_2$. Salt.—PbA'_2 [70°].

Tri-*iso*-amyl-tetra-thio-phosphate $(C_5H_{11})_3PS_4$. Formed, together with the preceding, when P_2S_5 acts on isoamyl alcohol (Kowalewsky, *A.* 119, 310).

Iso-**AMYL THIOSULPHATE.** The salt $Na(C_5H_{11})S_2O_3 2aq$ is formed by acting with isoamyl iodide on sodium thiosulphate. It crystallises in laminæ (Spring a. Legros, *B.* 15, 1938).

Iso-**AMYL THIO-UREA** $C_6H_{14}N_2S$ *i.e.* $C_5H_{11}NH.CS.NH_2$. Monoclinic crystals (Arzruni, *P.* 152, 284).

AMYL-TOLUENE $C_{12}H_{18}$ *i.e.* $CH_3.C_6H_4.C_5H_{11}$. *Methyl-amyl-benzene*

o-Iso-**amyl-toluene** (?). (204°). S.G. ^{0} ·895. From toluene, isoamyl chloride, and zinc dust (Pabst, *B.* 9, 503).

m-Iso-**amyl-toluene**. (208°). S.G. ^{22} ·868. From toluene, isoamyl chloride, and $AlCl_3$ (Essner a. Gossin, *Bl.* [2] 42, 213). $KMnO_4$ gives isophthalic acid.

p-Iso-**amyl-toluene**. (213°). S.G. ^{0} ·864. From *p*-bromo-toluene, isoamyl bromide, and Na (Bigot a. Fittig, *A.* 141, 160). CrO_3 produces terephthalic acid.

AMYLUM *v.* STARCH.

AMYL-UREA $C_6H_{14}N_2O$ *i.e.* $C_5H_{11}NH.CO.NH_2$.

Iso-**amyl-urea** [91°]. From amyl cyanate and hot alcoholic NH_3 (Custer, *B.* 12, 1330; *cf.* Wurtz, *C. R.* 32, 417; *Bl.* [2] 7, 141). Crystals; sl. sol. water.

Iso-Hexoyl-derivative $C_5H_{11}NH.CO.NH.CO.C_5H_{11}$. [94°]. From the amide of isohexoic acid, $Pr.CH_2.CH_2.CO_2H$, by means of Br and NaOH (Hofmann, *B.* 15, 758).

Tert-**amyl-urea.** [151°]. S. 1·26 at 27°. From tert-amyl cyanate and NH_3 (Wurtz, *A.* 139, 328).

n-Hexoyl derivative. [97°]. Formed by action of potash on a mixture of *n*-hexamide and bromine (H.). Plates; sol. alcohol, and ether, insol. water.

Di-*iso*-amyl-urea $C_5H_{11}NH.CO.NHC_5H_{11}$. [39°]. (270°). Formed by boiling isoamyl cyanate with isoamylamine and alcohol (C.). Needles; insol. water, sol. alcohol and ether.

Di-*tert*-amyl-urea. Formed by action of KOH upon tert-amyl cyanate (W.). Needles; may be sublimed.

Tri-*iso*-amyl-urea $(C_5H_{11})_2N.CO.NH.C_5H_{11}$. (260°). From isoamyl cyanate and di-isoamylamine (C.). Liquid.

Tetra-*iso*-amyl-urea $(C_5H_{11})_2N.CO.N(C_5H_{11})_2$. (241°). Obtained by the action of $Cl.CO_2Et$ upon a mixture of di- and tri- isoamylamine (C.).

AMYL URETHANE *v.* AMYL-CARBAMIC ETHER.

AMYL-VALERONE *v.* BUTYL ENNYL KETONE.

Iso-**AMYL-XYLENE** $C_{13}H_{20}$ *i.e.* $C_6H_3Me_2.C_5H_{11}$. *Di-methyl-isoamyl-benzene.* (233°). S.G. ^{2} ·895. From bromo-xylene, isoamyl bromide and Na (Fittig a. Bigot, *A.* 141, 168).

AMYRIN. A crystalline resin, difficultly soluble in alcohol, contained in some specimens of elemi, and in arbol-a-brea resin (Buri, *Neues Repert. für Pharm.* 25, 193; Hesse, *A.* 192, 179). According to Hesse its formula is $C_{47}H_{76}(OH)_2$ and its acetyl derivative is $C_{47}H_{76}(OAc)_2$. Bromine forms a complicated bromo-derivative.

ANACARDIC ACID $C_{22}H_{32}O_3$. [26°]. Occurs in the fruit of *Anacardium occidentale* (Staedeler, *A.* 63, 137). Crystals; insol. water, v. sol. alcohol and ether. **Salts.**—CaA″aq.—BaA″.—PbA″.—HA″PbOAc.—A″FeOH aq. –AgHA″.

ANALYSIS. To analyse a thing means to resolve it (ἀναλύειν) into its components. This term, however, has a very wide meaning, which stretches far beyond the outermost limits of our resources of even *virtual* analysis. So well is this understood by all that even when we speak of a complete analysis we refer only to as complete a solution as the science affords of one or other of three special problems. One of these is the actual or virtual resolution of the body into its component chemical species or perhaps genera; another, the determination of its elements; the third, the determination of what, in the sense of some imagined general mode of decomposition, are its primary radicles. This (the last named) problem has received a partial solution in the sense that we have ready-made methods for the determination of the acids and bases that may be contained in a solution of salts of a certain low order of complexity. These methods include only a minority of the non-metallic salt radicles, but they include all the better-known elements as such; and as we have general methods for converting any kind of substance into salts of low order of complexity, these latter methods, conjointly with the former, constitute a complete solution of the problem of *ultimate analysis*. In regard to the first problem, our powers are very limited. That we have methods for the proximate analysis of certain classes of substances need not be specially affirmed; without these, vegetable and animal chemistry could have no existence—but a general exposition of their principles would resolve itself into the retailing of commonplaces. We prefer to give a brief summary of what we have of means and ways for seeing whether a substance presumed to be pure really is one substance or is a mixture. In a sense there is only one method: we subject the substance to some physical or chemical process of fractionation, which, while sure not to produce transmutations, gives the several proximate components a chance of parting from one another; and we then compare the several products with one another and with the original substance. The form which the method assumes depends largely on the state of aggregation of the substance under operation.

I. Gases. The oneness of a gas can in general be proved by (*a*) *fractional diffusion* through a septum of gypsum or graphite; if the gas is a mixture of, say, two species, the lighter one diffuses out faster than the other; with mixtures of gases of the same specific gravity, the method, of course, breaks down: (*b*) *partial absorption.* This method is discussed fully under 'gas-analysis' (*q. v.*).

II. Solids. These may be susceptible of fractionation by (*a*) *partial fusion*; (*b*) *partial solution* in suitable solvents; (*c*) *partial freezing of the liquefied body*; (*d*) *partial crystallisation* out of solutions; (*e*) *partial volatilisation.* (See III.) For the comparison of the several fractions, the determination of the fusing points comes in as a handy, and in general sensitive, test.

III. Liquids. For these the methods given under (*b*) and (*c*) for solids may be available. In the case of distillable liquids we generally resort to fractional distillation, taking care to observe the temperature of the (saturated) vapour, during the progress of the operation. A mixture may have a constant boiling-point, and may besides remain undecomposed on distillation; as a rule, however, it is not so. The volatility of each component depends chiefly on the value for it of the product mp, where m is the molecular weight (or vapour density), and p the vapour-pressure at the prevailing temperature of ebullition. For two components, the respective products m_1p_1 and m_2p_2 have in general different values. Hence it is not necessarily the lowest boiling component which comes over first; because a large m may make up for a small p. As a mere test for purity, the determination (at a series of suitable temperatures) of the vapour-pressure by the statical method goes considerably further than the determination of the boiling-point curve. In a pure substance, the pressure, p, at $t°$ is a function of t only; in a mixture of (say) two liquids, p depends (in a given trial) on the volume of vapour produced, because the ratio of the weight of the vapour to that of the unvolatilised residue changes with this volume. If this ratio is very small, we have an approximation to the vapour-pressure of the more volatile component; if the ratio is large, the pressure approaches the value characteristic of the mixture as such. Any of the many mixtures of constant boiling-point, when subjected to this test, at a suitable temperature, is sure to reveal its complexity. Unfortunately the operations involved are somewhat troublesome, and the results are liable to be largely vitiated by the presence of absorbed air in the sample.

The second and third of our three general problems, qualitatively considered, form the body of what is customarily being taught as

Qualitative Analysis.

The resources of qualitative analysis—apart from mere methods of identification of named species, which we leave on one side—may be arranged under three heads:—

I. Flame Tests. A set of methods for the detection of elements as such, which, being all founded upon ultimate or penultimate dissociations at high temperatures, are in a high degree independent of the constitution of the substance operated upon. Another specific feature in these tests is that they are easy and rapid of execution, and demand only very small quantities of substance.

II. A set of what we will call methods of chemical disintegration (each general in reference to a large class of bodies), by means of which compounds of high chemical complexity can be, so to say, opened up, and their elements brought within the range of our routine methods of salt analysis (*v. infra*). These methods might, each, be indexed, by reference to a certain element, generally of high valency; as a rule it is a non-metallic element, and in the analyst's sense, *sui generis*, *i.e.* not susceptible of detection as one of a group.

III. The systematic methods for the radical analysis of a solution of salts which were referred to in the introduction. In addition to these analytical methods, the analyst naturally discounts all that may help him towards the solution of his problem. Our three classes of methods alone, it is true, if judiciously employed, would enable one in general to perform an exhaustive ultimate analysis; but a purely ultimate analysis, in the majority of cases, is not what we want. The ideal which we aim at in all analyses made for practical purposes is (as good an apology as is attainable for) a proximate analysis; a recipe, so to say, for composing the substance from things of known constitution. Hence, if the substance presents the aspect of a mixture—mechanical or physical—we naturally begin by trying to effect a separation of the several things from one another: by mere picking out, or elutriation, in the case of an obvious mixture; by distillation in the case of a solution in a volatile solvent. We will assume, however, that this division of the given substance into two or more substances has been effected (if called for, and possible), and that the substance to be analysed is a solid (which virtually includes the case of a liquid); gases demand special methods, which lie beyond our programme. In this, as in any analogous case, we naturally begin by a close observation of at least the general properties of the body; it may be expedient to supplement this observation by the exact determination of certain physical properties, such as hardness, specific gravity, crystalline form, optical constants, &c., &c. Everything here depends on the nature of the case, and—of the operator. A mineralogist, for instance, by such determinations, may be able virtually to analyse a mineral; but everybody cannot do this. After the more purely observational stage, it is expedient to study the behaviour, at a graduated succession of high temperatures, of (*a*) the substance itself, (*b*) the substance and atmospheric oxygen, (*c*) the substance plus added reagents. We therefore begin by heating a few centigrams of substance in a sublimation tube over a Bunsen lamp—first gently, then more and more strongly—on the chance of obtaining a readily recognisable sublimate, gas or vapour, or residue. Of the identifiable residues, charcoal is the most important, because its formation proves the presence of *organic* matter in the sample, although all organic matter does not yield charcoal. If [illegible] substance presents a metallic, or semi-[illegible]llic, aspect, it is expedient to roast a frag-[illegible] in a draught-tube, on the chance of [illegible] a sublimate of mercury, oxide of [illegible] white arsenic, iodine, &c., or an [illegible] sulphurous acid, &c. If the sub-[illegible] partially volatile or partially [illegible] we prepare a supply of the fire-proof [illegible] west sufficient temperature), and, [illegible] the first as we would a fire-proof [illegible] ubject it to a selection of

I. Flame Tests.

By "flame-tests" we mean dry-way tests, in which the substance, or substance plus reagents, is heated directly in the flame. These tests were introduced by Gahn, and subsequently extended and brought to high perfection chiefly by Berzelius and Plattner. In accordance with the modes of operating which these authorities found it convenient to adopt, a blowpipe flame used to be universally employed as a heating medium. But Bunsen, some twenty years ago, showed that most blowpipe tests can be done more easily and conveniently in the flame of the gas lamp which bears his name, and that this flame can also be employed for certain new tests introduced by him, which tests could not be conveniently done with the blowpipe. Many chemists prefer the Bunsenian *modus operandi*, but the blowpipe has not by any means become obsolete; it will continue to be used, because it offers certain specific advantages of its own. For the purposes of this article it will be sufficient to give the following enumeration of the more important of the characteristic flame-test operations:

(1.) A few mgms. of the substance are placed on an asbestos-stick, and exposed to the several regions of a Bunsen-flame, proceeding from lower to higher temperatures, to determine degrees of fusibility and volatility.

(2.) A few mgms., fixed to one end of a hair-fine platinum wire, are exposed first to colder, and then to the hottest, part of the flame-mantle of a Bunsen, in order to see whether the flame is thereby coloured. If a colour is produced, it is analysed optically (by means of a spectroscope), with the view of thus effecting a chemical analysis of the glowing vapour. Of elements identifiable by their spectra (or flame colours), the following may be named:—Tl, In, Rb, Cs, K, Na, Li, Ba, Sr, Ca in most of the ordinary states of combination, Cu as haloid salts, B as boric acid or fluoride, P as free phosphoric acid or PH_3.

Spectrum analysis, as everybody knows, was invented by Bunsen and Kirchoff. Some years ago Bunsen brought it into a new form, in which a spark current, produced by means of an induction-coil is used for the volatilisation of the substance; at the very high temperatures thus produced, a great many elements, besides those named, become identifiable by their spectra.

Flame Tests with Reagents.—Of these *sodium carbonate* is most extensively employed; either platinum wire or charcoal being used as a support.

On platinum; (1) as a mere flux, it identifies SiO_2, given as such or as highly acid silicate; (2) in conjunction with oxygen used as air, or introduced as nitre—it detects Cr and Mn with certainty, converting the former into (yellow) chromate, the latter into (green) manganate.

When used on charcoal; in the reducing flame, it may bring to light, (1) S, Se, Te. Any non-volatile form of these yields a fused mass, containing Na_2S &c., recognisable by the black stain (Ag_2S &c.) which it produces when placed on a silver coin, and moistened with a drop of water.—(2) *One or more of the following metals*; **As, Hg, Zn, Cd, Pb, Bi, Sn, Cu, Ag, Au, Fe, Ni, Co, Pt.** The oxides and many of the salts of these metals when subjected to the operation under discussion, are reduced to the elementary state. The metal thus liberated may assume the form of a visible fused bead, or remain concealed in the form of fused scales or an unfused powder or sponge; these, however, can in all cases be isolated and brought to light by elutriation with water in an agate mortar. Part of the metal, in general, volatilises, and in passing through the flame becomes oxide. If the reduction is effected in the blowpipe flame on a block of charcoal (old style), part of the oxide in general settles down on the charcoal as a ring, and by its colour may aid in identifying the metal. When operated upon as described, compounds of As yield only vapour of oxide, which in most cases is lost altogether. Hg; vapour of metal, which is also lost. Zn, Cd; little or no metal, but abundant oxide rings; (ZnO is white, CdO brown). Pb, Bi; easily fusible metal, and tangible quantities of yellow oxide. Sn; easily fusible metal, and little (white) oxide. Cu; not easily—Ag; more easily —Au; not easily—fusible metal or scales, and no oxide. Fe, Ni, Co; unfused powdery, or spongy, metal, which follows the magnet. No oxide. Pt; like Fe, but the metal is not magnetic and is unacted on by HNO_3Aq.

In Bunsen's mode of operating—which consists in heating the mixture of substance and soda on a slender stick of charcoal in the reducing part of the 'zone of fusion,' the oxide is lost, but all the respective metals fall within the range of

Bunsen's Film Tests.—When the air-holes of the Bunsen are partially closed, a luminous tip forms somewhere near the apex of the flame. Many oxides suffer reduction when held in the centre of this tip on an asbestos stick; and the reduced elementary substance can be collected on a Berlin basin (filled with water to keep it cold), held over the sample across the flame. The elements thus appear as films resembling the stains of As and Sb produced in Marsh's test. The following elements chiefly yield films: As, Sb, Te, Se; hardly attacked by nitric acid of 20 p.c. Bi, Hg, Tl; very slowly dissolved by nitric acid of 20 p.c. Pb, Cd, Zn, In; instantly dissolved by nitric acid of 20 p.c. By a very obvious modification of the process, oxide films can be produced in lieu of metallic ones; but we cannot go any further into this matter.

Borax is always used as a bead fused to the end of a platinum wire. Such a bead dissolves most metallic oxides at a moderately high temperature, forming glasses, the colours of many of which are characteristic of the metal. Often one metal gives two colours according to whether the fusion is effected in the oxidising or in the reducing flame; this affords additional means of discrimination.

Microcosmic salt (or rather the fused $Na_2O.P_2O_5$ produced by its decomposition by heat) acts on metallic oxides pretty much as borax does; but its specific function is the detection of *silica*. If a splinter of a silicate is heated in a fused meta-phosphate bead, the bases dissolve out, the silica remains in the characteristic form of an unfused 'skeleton' of the splinter.

Whatever the flame-tests may have brought out by way of positive results, their negative results count for very little.

II. Methods of Chemical Disintegration.

Substances may be divided into two classes, as regards the operations required to bring them within the range of our systematic methods of salt-analysis. (1) Such as are simple salts (we mean salts which can be analysed by our routine methods), or can be made into solutions of such by the application of the ordinary mineral solvents, such as water, dilute mineral acids (*qua* acids), nitric acid or aqua regia (*qua* oxidants). This class comprises many minerals, and ordinary chemical bodies, but unfortunately (and naturally) we have no general test for the recognition of these bodies as a class. (2) Such as demand special methods of disintegration. Of the more commonly occurring chemical genera, the following may be named as falling within this class:—(*a*) *Fluorides*; these although perhaps of the simplest constitution, demand special methods because hydrofluoric acid and all acid fluoride-solutions attack glass and porcelain. (*b*) Most *silicates*: *silico-fluorides.* (*c*) *Cyanides*, especially *metallocyanides.* (*d*) *Salts of certain complex organic acids* (not cyanides); in the sense that they exhibit abnormal metal-reactions. (*e*) *Organic compounds* generally; in the sense of ultimate analysis generally. (*f*) *An-orthophosphates.* (*g*) Certain classes of *sulphur compounds.*

This list does not pretend to be complete, but it includes most bodies which the practical analyst is likely to come across. For the second class of substances as a class, we of course have not a general test any more than we have for the first, but we have general tests for the several genera, in this sense at least that we have general methods for the detection of their characteristic elements.

The following section is compiled partly with the view of supplying the necessary information in this direction.

General methods for the detection of certain elements (mostly non-metals) and for the ultimate analysis of their compounds.

Silicon is always isolated in its highly characteristic form of *silica*, SiO_2, which is easily identified by the blowpipe tests given above, and by its convertibility into volatile SiF_4 by the action of HF. *Silicon and metallic silicides*, when fused with caustic alkali, yield alkaline silicates (*q. v.*). *Alkaline silicates* (even if so acid as $R_2O.4SiO_2$) dissolve in water, forming alkaline solutions. *Mineral silicates*, *Slags*, *Glasses*, *&c.* fall within two classes according to whether they are, or are not, decomposable by hydrochloric acid. Those of the first class are finely powdered and digested in conc. hot HClAq until disintegrated, evaporated to *complete* dryness (to convert the colloidal part of the silica into the insoluble form), drenched with HClAq, allowed to stand (to re-chlorinate the Al_2O_3 and Fe_2O

produced), treated with water, and filtered. The silica remains on the filter; the solution contains the metals as chlorides. Of those of the second class, some are disintegrable by hot semi-conc. H_2SO_4Aq (ex. the clays). The general method is to fuse the finely powdered silicate with $KNaCO_3$ until all is dissolved, and to analyse the fused residue as a silicate of the first class. Alkalis must be tested for in another portion of the silicate, after evaporation with NH_4FAq, whereby Si is removed as SiF_4 and the bases remain as fluorides easily convertible into sulphates by H_2SO_4Aq (comp. **Fluorine**).

Aluminium.—Only the forms of Al_2O_3 insoluble in acids need be considered here; these if *finely enough divided*, all dissolve at a red-heat in fused KOH, becoming aluminates soluble in water.

Chromium.—All non-volatile compounds, when fused (in silver) with KOH and KNO_3, yield alkaline *chromate*, recognisable by its yellow colour and the *very* intensely yellow colour of its aqueous solution. This operation constitutes a general method of disintegration for the forms of Cr_2O_3 and chromites insoluble in acids; it goes a certain way even with *chrome iron ore*, but the complete disintegration of this mineral demands special methods.

Titanium.—TiO_2 stands between SiO_2 and Al_2O_3. Unlike the former it is not volatilised by evaporation with HFAq. Titanates are decomposed by fusion with $KHSO_4$; the cold aqueous extract after fusion includes the TiO_2 which is precipitated on boiling, as such.

Tin.—The forms of SnO_2 (including tinstone) which are insoluble in acids yield Sn when fused on charcoal with $NaHCO_3$ and KCN. They may be disintegrated (1) by fusion with KOH; the SnO_2 becomes stannate soluble in water: (2) by fusion with six pts. S and six pts. Na_2CO_3; the aqueous extract after fusion contains the Sn (also any As and W that may be present) as *thiosalt*, and consequently falls in with a certain stage of the routine method of metal-analysis (*v. infra*).

Carbon in any state of combination is convertible into CO_2, which is readily identified. It is distinguished from HCl and SO_2 by its scanty solubility in water, and inertness towards oxidising agents; from N, H, &c. by its abundant solubility in solutions of basic hydrates; with CaO_2H_2Aq and BaO_2H_2Aq it gives a characteristic white pp. of carbonate. *Carbonates* (almost without exception) are decomposed by mineral acids with evolution of CO_2. *Elementary carbon* (in all forms) burns in oxygen to CO_2.

Combustible Carbon Compounds.—The methods of organic analysis (*q. v.*) are easily translated into general methods for the detection of combustible carbon as CO_2. It is *necessary* to purify the CuO or $PbCrO_4$ immediately before use by heating it to redness in air until it ceases to give off CO_2.

All non-volatile carbon compounds can be burnt by heating them with conc. H_2SO_4Aq and CrO_3. Many volatile organic bodies unite readily with conc. H_2SO_4Aq to form non-volatile compounds, and thus fall within the range of the method which obviously suggests itself for the detection of *combustible carbon beside carbonate*.

Analysis of Carbon Compounds.—I. *Organic acids proper* (COOH compounds) need here be considered only in regard to the extent to which they interfere with the routine methods for the detection of the metals in a solution of salts. Some (including formic, acetic, succinic, and *many* others) interfere only in this sense that, in their presence, the precipitate obtained by H_2S in the presence of free acid, may include Zn, Co, Ni, and perhaps other metals of the iron group. This difficulty is easily overcome. A large class of non-volatile acids, including the ordinary fruit acids, prevent the precipitation of Fe_2O_3, Al_2O_3, Cr_2O_3, CuO, and other metallic oxides by alkalis, and that of Al and Cr even by sulphide of ammonium. In all difficult or doubtful cases, it is best to destroy the organic part of the salt, which can be done in two ways:—(1) *By incineration*: which, of course, had better be postponed until after the elimination of the copper and arsenic groups by sulphuretted hydrogen; if this has been effected, Zn, of all the metals left, is the only one which may be lost by volatilisation.—(2) By *treatment* (of the dry salts) *with oil of vitriol*. The ultimate product contains the metals in the form of sulphates.

II. *Cyanides*. *a*. **Hydrocyanic acid**; easily recognised by its volatility and specific smell and reactions; regarding the latter, see *b*. *b*. **The simple cyanides of the more positive metals** (K to Ca inclusive). These are all soluble in water. The solutions are alkaline, and give off HCN with acids. $AgNO_3Aq$ in excess precipitates AgNC, insoluble in dilute HNO_3Aq. When mixed with (1) excess of alkali, (2) ferroso-ferric salt, (3) excess of HClAq, they yield a blue precipitate (or green suspension) of Prussian blue. *c*. **Cyanide of mercury**, $Hg(NC)_2$. Soluble in water. Exhibits anomalous reactions both as a mercuric salt and as a cyanide. But is decomposed by H_2S into a pp. of HgS and a solution of HCN. *d*. **Heavy metallic cyanides, and metallocyanides.** Some give off part of their cyanogen as HNC, when distilled with dilute HClAq or H_2SO_4Aq. Many (*e.g.* prussiates) recognisable by specific tests. Solutions of metallocyanides mostly give pps. with $AgNO_3Aq$, insoluble in dilute HNO_3Aq, in which the characteristic metals of the radicles can be detected (*v.* **Halogens**).

A general method for the detection of the metals in cyanides, cyanates, and thiocyanates, is to heat the dry substance with conc. H_2SO_4Aq until completely decomposed. The cyanogen becomes ammonia-salt, and CO; the metals remain as sulphates. About the detection of non-metallic elements in carbon compounds, see sect. on S, P, &c.

Boron occurs chiefly in the form of borate. The presence of boric acid does not interfere with the routine methods of metal analysis.

Phosphorus is always isolated and identified as orthophosphate. I. *Orthophosphates*, as far as not soluble in water, are mostly soluble in HClAq. To search for phosphoric acid, we supersaturate the solution strongly with ammonia, and (after filtration, if necessary) add magnesia mixture (NH_4Cl and $MgCl_2$ in NH_3Aq), crystalline $PO_4MgNH_4.6H_2O$ gradually forms, insoluble in dilute NH_3Aq. A pp. formed by

NH_3Aq generally contains part, sometimes the whole, of the phosphoric acid. To detect the latter we dissolve the pp. in HNO_3Aq, add excess of a nitric solution of molybdate of ammonia, and allow to stand at 40°C. All the phosphoric acid comes down gradually as a yellow powdery pp. of phospho-molybdate of ammonia, insoluble in excess of reagent, but soluble in excess of acid phosphate; soluble in ammonia. Both reactions are very delicate, and, in the absence of arsenic acid (which in the circumstances behaves like phosphoric), highly characteristic. Phosphates in any other state of combination can be brought into the orthophosphate form by suitable operations. II. *Meta- and pyrophosphates* (which besides being different in their own reactions from orthophosphates, exhibit anomalous metal-reactions); by long-continued boiling with mineral acids, or (what is better) fusion with carbonate of alkali. III. *Elementary phosphorus*, and all oxidisable phosphorus compounds; by treatment with HNO_3Aq of the proper strength at the proper temperature. Many organic phosphorus compounds, it is true, cannot be thus completely oxidised, but in their case, we need only neutralise the nitric liquor produced with potash, evaporate to dryness, and fuse the residue with KOH, to convert all the phosphorus into orthophosphate.

Sulphur.—Analytically speaking, sulphuric acid is to sulphur what orthophosphoric acid is to phosphorus. I. *Sulphates*, in an aqueous or HCl solution, are separated out completely by $BaCl_2Aq$, as white, powdery, $BaSO_4$, insoluble in aqueous mineral acids, and thus distinguished from all the baryta-pps., except the selenate and fluosilicate. $BaSeO_4$ is decomposed by boiling HClAq with formation of Cl and SeO_2, while $BaSO_4$ is not so decomposed. The fluosilicate yields *no sulphide* on fusion with Na_2CO_3 on charcoal; and dissolved fluosilicates give no pp. with $SrCl_2Aq$, while sulphates yield a pp. of $SrSO_4$, slightly soluble in dilute acids. II. *Acid-insoluble sulphates* are disintegrated by fusion with alkaline carbonate, and treatment with water; a solution of alkaline sulphate, and a residue of the respective carbonate, oxide, or metal, are obtained. III. *Metallic sulphides.*—Many are decomposed by HClAq with evolution of H_2S. IV. *The salts of the lower sulphur acids*, when heated (in solution) with alkaline permanganate are completely oxidised with ppn. of manganite, $MnO_2.R_2O$. The excess of oxidant used is brought into the same form by addition of a few drops of alcohol. The filtrate contains all the sulphur as sulphate. Only dithionic acid does not yield readily to this process of oxidation. All the sulphur compounds III. and IV., including dithionates, and *many organic sulphur compounds*, are oxidised completely by hot, sufficiently conc. HNO_3Aq. Volatile compounds (such as CS_2) must be manipulated in a sealed glass tube. From some organic bodies only sulphonic acids are produced; but these, when fused with KOH and KNO_3 all yield up their sulphur as sulphate.

All oxidisable sulphur compounds are completely oxidised to sulphates by the action of basic reagents (like Na_2CO_3, CaO, &c.), and KNO_3, or even oxygen-gas, at a red heat. All non-volatile sulphur compounds yield alkaline sulphide when fused with Na_2CO_3 on charcoal in the reducing flame (*v.* FLAME TESTS).

Selenion and Tellurium are closely allied to sulphur, but must be passed over.

Nitrogen, in all states of combination, is susceptible of elimination as nitrogen gas, recognisable by the methods of gas-analysis. Another less general, yet widely applicable and more convenient, method is based upon the conversion of the element into ammonia.

I. *Ammonia*; recognisable by its smell, its great solubility in water, its ready union with HCl to form solid NH_4Cl, &c. The least traces of NH_3, or NH_4 salt in water, are detected by Nessler's reagent (a solution of HgI_2 and KI in KOHAq); iodide of mercurammonium separates from moderately dilute solutions, as a brown pp., and even in the most dilute solutions is visible as a brown or yellow colour. II. *Ammonia salts*; many amides (including all acid-amides) when distilled with caustic alkali, yield NH_3 which passes into the distillate. III. *Nitrates and nitrites* in alkaline solutions are reduced by *nascent hydrogen* (KOHAq and Al) to NH_3. IV. *Metallic nitrides*, and all organic nitrogen compounds not containing their nitrogen in the form of oxygenated radicles or in the diazo-form, when burnt with soda lime yield their N as NH_3.

Fluorine. Most metallic fluorides, when treated (as powders) with conc. H_2SO_4Aq in a platinum crucible at a gentle heat, give off HF, recognisable by its etching glass and even rock-crystal. For the purpose of metal-detection, the mass must be evaporated until a tangible quantity of sulphuric acid has gone off as a heavy vapour. The bases remain as sulphates.

Mixtures of *fluorides and silicates*, when heated with conc. H_2SO_4Aq give off SiF_4, decomposed by water into H_2SiF_6Aq and a gelatinous pp. of SiO_2, which, however, may be invisible. To detect the fluorine, add excess of ammonia to bring down all the silicon as silica (which filter off), and evaporate the filtrate in platinum on a water-bath nearly to dryness. Residue is fluoride of ammonium.

Fluosilicates. Those of the most basylous metals when heated dry break up into SiF_4 and a residue of fluoride. Fluosilicates generally behave to boiling alkali solutions as if the silicon were a basylous metal.

The Halogens (Cl, Br, I). I. *The elementary substances* are recognised by their very characteristic properties. When treated with zinc and water, they all dissolve as haloid salts of zinc ($ZnCl_2$, &c.). II. *Haloid salts*; mostly dissolve in water or in HNO_3Aq. Even from the latter solution the halogen is completely ppd. as haloid salt of silver, insoluble in dilute mineral acid. III. *The oxygen acids of the halogens.* (Periodic acid ignored.) Of these only bromic and iodic give silver pps. insoluble (or soluble with difficulty) in cold, dilute, HNO_3Aq. All the rest form soluble silver salts. Their alkali and alkaline-earth salts when heated dry give off oxygen and become haloid salts. With the only exception of *perchloric acid* they are all reduced by SO_2Aq to halogen-hydride (*e.g.* $HClO_3$ to HCl). Hence an obvious IV. *Relatively general method for the detection of halogen in a solution of salts.* The solution (which we will assume to be neutral or acid) is mixed with excess of SO_2Aq and $AgNO_3Aq$, the pp. is allowed to form, and then treated with HNO_3Aq, to remove foreign salts (including Ag_2SO_4 which is not very readily dissolved). The pp. contains all the halogen of the solution, (except that of the perchloric acid); but it may besides contain—if it does not consist of—cyanide, thio-cyanate, and metallo-cyanates, of silver, (not to mention the sulphide which is easily kept out). An analysis can be effected by calcining the dry pp. with chemically pure soda-lime, preferably in a current of moist hydrogen. The nitrogen of the cyanogen radicles goes off as ammonia, which is easily identified. The residual product contains the metals of the metallo-cyanates as oxides, the silver as metal, the sulphur of the sulphocyanogen as alkaline sulphide, and the halogens as alkaline haloids. V. *Organic halogen compounds.* All these, when burnt with quick-lime in a combustion tube, yield up their halogen as haloid salt of calcium, extractable by cold, dilute, HNO_3Aq.

III. Methods for the Systematic Examination of a Solution of Salts for its Metals

can be given only on the basis of restrictive assumptions. We assume, in the outset at least, that the solution is so constituted that it might have been prepared by dissolving a set of basic or acid metallic oxides in aqueous mineral acid or alkali, and that certain rare oxides and certain rare combinations of things are absent. Some of the cases lying beyond this programme are dealt with in appended notes to which reference is made in the context. For the sake of generality, however, we assume that all the more ordinary metallic radicles may be present. It evidently would not do to search for them individually and seriatim; the only course one could reasonably think of is to begin by splitting up the given complex group of metals into a number of groups, so that each of these shall contain the whole of, and nothing but, certain metals, A, B, C, . . .; to then apply the same principle to the groups; and then to the groups of the second order; and so on until one arrives at last at either the individual metals, or at groups of such smallness that the side-by-side recognition of their members offers no difficulty. This, at any rate, is the course which is adopted by every chemist. The table on p. 221 in its first vertical column names the generic reagents which are customarily used for the formation of primary groups, and shows how these act on solutions of the groups of oxides named in the successive column headings. For the *separation* of the groups from one another it is obviously expedient to begin by eliminating the *silver group* by means of hydrochloric acid, which must be added in instalments until the solution is decidedly acid, and, if a permanent pp. appears (which with us can consist only of these three chlorides), until the ppn. is completed.[1] The pp. contains all the silver and mercurosum as AgCl and Hg_2Cl_2, but only part (if any) of the lead; a small quantity of this metal always passing into the filtrate. From the filtrate the copper and arsenic groups are ppd. conjointly by means of sulphuretted hydrogen. Before applying this reagent, however, we must make sure of the at least relative absence of nitrous, nitric, and chloric, acid and other oxidising agents, which, while not easily or completely reducible by H_2S would at least tend to oxidise it and impede its normal action. Any of the three oxidants named can be expelled by repeated evaporation to a *small volume* with conc. hydrochloric acid.[2] The last residue is diluted with the proper proportion of water, and (heedless of any insoluble oxychloride that may separate out) treated with sulphuretted hydrogen, first at about 70° to make sure that As_2O_5 is completely reduced to As_2O_3, and its metal ppd. (as $As_2S_3 + S_2$), and then again after cooling, or else part at least of the cadmium and other copper-arsenic group metals, whose sulphides are rather unstable in opposition to aqueous acids, would escape ppn.

On account of the metals just referred to, we must see that the quantity of free mineral acid is not excessive, but is sufficient to prevent the ppn. of the zinc, which from only feebly acid solutions is liable to pass into the sulphuretted hydrogen pp.

The ppd. sulphides are collected on a filter and washed with very dilute sulphuretted hydrogen water, to constantly re-sulphurise what may have become sulphate by the action of the air; the first instalments of wash-water being acidified to the extent of the mother liquor, to prevent ppn. of the zinc. In order now to separate the two groups, the pp. is digested on a water-bath heat with undiluted *yellow* sulphide of ammonium; an excess of sulphur in this reagent being necessary, chiefly on account of the stannous sulphide, SnS, which becomes soluble only through conversion into stannic, SnS_2. To effect a complete separation, the treatment with sulphide of ammonium may have to be repeated with the first residue. The copper-group sulphides are filtered off and washed with warm water mixed with a little sulphide of ammonium. From the filtrate the arsenic-group sulphides are reproduced by acidification with dilute sulphuric acid; after expulsion of the dissolved sulphuretted hydrogen by a gentle heat, they are filtered off, and washed with plain water (sulphuretted hydrogen water would dissolve sulphide of arsenic As_2S_3). The pp. is liable to be contaminated with sulphide of copper; this can be eliminated by treatment with warm dilute caustic potash, which dissolves the arsenic-group sulphides

---

[1] If the solution contains Tl, the metal passes for the most part into the pp., where it is easily detected by spectrum analysis. The characteristic solubility of its chloride in Na_2CO_3Aq enables one to separate it from the ordinary silver-group chlorides.

In an *alkaline solution of salts generally*, HClAq may produce a great variety of permanent pps. other than silver-group chlorides. For the purpose of a mere metal-analysis a pretty safe rule is this. If a solution on adding HClAq gives an abnormal-looking pp., repeat the experiment with HNO_3Aq; if no permanent pp. is produced, HClAq will act normally as a chloride; if a pp. is formed, it must be filtered off and analysed for the metals that may be in it, (as sulphides, *e.g.* As_2S_3; or chlorides such as AgCl, &c., &c.). The solution, as a rule, is now fit for treatment with hydrochloric acid, &c.

[2] In evaporating a solution of metallic oxides with HClAq, it is as well to remember the volatility of $AsCl_3$, $SbCl_3$, $SbCl_5$, $SnCl_4$, $BiCl_3$. The evaporation is best conducted in a retort, and these volatile chlorides are searched for in the distillate.

GENERIC REACTIONS OF MINERAL-ACID SOLUTIONS OF GROUPS OF METALLIC OXIDES.

Reagents.	Silver Group.	Copper Group.	Arsenic Group.	Iron Group.		Barium Group.	Magnesium Group.	Alkali Group.
				R″O.	R_2O_3.			
	Ag_2O, Hg_2O, PbO.	HgO, CuO, Bi_2O_3, CdO [PbO].	As_2O_3, Sb_2O_3, SnO, SnO_2.	FeO, MnO, ZnO, NiO, CoO.	Al_2O_3, Cr_2O_3, Fe_2O_3.	BaO, SrO, CaO.	MgO.	K_2O, Na_2O, $[(NH_4)_2O]$.
Hydrochloric acid.	Metals precipitated as chlorides.	Metals remain dissolved.						
Sulphuretted hydrogen and free acid.	Metals precipitated as sulphides, insoluble in largely diluted acid.* Precipitate insoluble in ammonium sulphide.		Precipitate soluble in ammonium sulphide.†	Metals remain dissolved. The following oxides RO_x are reduced to lower oxides RO_y, with precipitation of white *sulphur*, and change of colour. $(RO_x)=Fe_2O_3$ $(RO_y)=FeO$ *Change of colour*: yellow to colourless. CrO_3 Cr_2O_3 Red to green or violet. Mn_2O_7 MnO Purple to colourless.				
Ammonium sulphide in neutral or alkaline solutions.	Arsenic Group, no precipitate. The rest precipitated as sulphides insoluble in excess of precipitant.			insoluble in excess of precipitant.	Cr and Al are precipitated as hydrates; Fe as Fe_2S_2+S.	In the absence of phosphoric, oxalic, and certain other, acids, no visible action.		No change.
Sal-ammoniac and excess of ammonia.	Metals behave differently.			Mn, Zn, Ni, and Co, no precipitate.	Fe_2O_3, Al_2O_3, Cr_2O_3 precipitated as hydrates.			
Ammonium carbonate.	Metals behave differently.					Metals precipitated as $R''CO_3$ insoluble in NH_4Cl.	In presence of NH_4Cl, no precipitate.	No visible change.
Dilute sulphuric acid.	Hg_2O and PbO precipitated as sulphates.	Metals remain dissolved, even in presence of moderate quantities of alcohol; excepting SnO_2, which may be precipitated.				Ba, Sr precipitated as RSO_4; Ca dil. sol.: no pp.; on addition of alcohol, $CaSO_4$ completely precipitated.	Metals remain dissolved, even in presence of moderate quantities of alcohol.	
Ammonium phosphate, NH_4Cl, and NH_3.	Many of these oxides are precipitated, more or less completely, as phosphates.						Slowly but completely precipitated as $PO_4MgNH_4+6H_2O$.	No precipitates.

* As_2O_5 only very slowly precipitated in the cold (more readily when heated), as $As_2S_3+S_2$. † SnS insoluble in colourless $(NH_4)_2S$; but soluble, as SnS_2, in yellow $(NH_4)_2S.S_x$.

only. From the filtrate, these sulphides can be recovered by acidification, in their original form. After elimination of the copper and arsenic groups, the *barium-group* may be separated out by means of sulphuric acid. The barium comes down at once (as $BaSO_4$), the strontium gradually, on standing and keeping warm. From the filtrate from these two sulphates the calcium can be ppd., after due concentration, by judicious addition of alcohol, and allowing to stand for, say, 12 hours. The calcium sulphate is filtered off and washed, first with dilute, and lastly with strong, alcohol. The filtrate, after removal of the alcohol, is ready for the elimination of the iron-group, &c. This method is the best that can be adopted if an analysis for the barium-group metals is our principal object; it also offers certain other specific advantages; yet the majority of chemists prefer (after application of sulphuretted hydrogen in the presence of acid) at once to separate out the *iron-group*, by means of sulphide of ammonium. The addition of this precipitant must of course be preceded by the neutralisation of the free mineral acid of the solution with ammonia; if a sufficiency of sal-ammoniac is not thus produced incidentally, some sal-ammoniac must be added, to bring the pp. into a fit condition for filtration. But we have no space for these technicalities, and accordingly assume the pp. to have been filtered off and washed with warm water mixed with some sulphide of ammonium, so as to remove the whole of the mother-liquor. This liquor, by theory, contains the whole, in practice it may be assumed in general to contain the bulk, of the barium-group metals and of the magnesium, in addition to the whole of the alkalis. For its analysis, the barium-group is ppd. by means of carbonate of ammonia added to a warm solution. In the presence of ammonia-salts, of which as a rule there is more than enough, only the barium-group metals are ppd. as carbonates; the pp. is collected on a filter, and washed with hot water. Part of the filtrate serves for the detection of magnesia by means of ammonium phosphate. The rest of the filtrate is evaporated to dryness, and the residue calcined. The ammonium-salts volatilise, or at least their ammonia does, and there remains a residue containing only magnesium and alkali-metals, which latter can be detected without elimination of the magnesium by suitable methods.

In regard to the analysis of the groups, our space does not permit us to do more than shortly indicate how the *sulphide of ammonium* pp. (which may be of very complex composition), can be split up into minor groups. Before doing so, let us state that in the presence of representatives of a certain group of acids which includes H_3PO_4,HF,H_3BO_3, and certain organic acids, *e.g.* oxalic, the pp. is liable to contain part, or all that there is, of barium-group metals and of magnesium, as salts of the acids named. A thoughtful analyst takes care to keep these inconvenient acids out of the solution; but the introduction of phosphoric acid is often unavoidable, and we therefore assume it to be present. Whether this acid is present or not, the *cobalt and nickel* can be eliminated, approximately at least, by treatment of the pp. with cold, dilute[1] HClAq, and removed by filtration. The filtrate is next tested for iron, best by adding a few granules of chlorate of potash and boiling, when the iron assumes the form of ferric salt, and becomes visible by the intense yellow colour of its hot hydrochloric solution, and at the same time assumes the right form for the next step, which aims at a separation of the metals present as Fe_2Cl_6, Al_2Cl_6, Cr_2Cl_6, and the phosphates, from the metals (manganese, zinc, &c.) present as dichlorides. Of the various methods which we have for their separation, the most convenient for general purposes is the following:—

After having made sure of the complete reduction of the manganese (Mn_2Cl_6) to manganous chloride by sufficient boiling with hydrochloric acid, we allow to cool, dilute pretty considerably, and next add (sal-ammoniac if necessary, and) ammonia, drop by drop, until the mixture is alkaline. We then (without losing time and giving the oxide of manganese much chance to get per-oxidised), boil until the vapours cease to smell of ammonia, and filter. The pp. contains all the iron, aluminium, and chromium, and all the phosphoric acid as lime-salt, or in other forms; the filtrate contains at least part of the zinc, manganese, and in general part of the rest of the protoxides. If the sesquioxide-pp. is bulky, it must be re-dissolved (after a few washings) and re-produced by a repetition of the first operation. From the *protoxide* filtrate, the zinc, after acidification with acetic acid, can be ppd. pure by fractional ppn. with sulphuretted hydrogen-water in the cold. The manganese, traces of nickel and cobalt, and in general much lime, baryta, and strontia, remain dissolved.

The *sesquioxides*-pp.[2] (if chromium be pre-

---

[1] *The cobalt-nickel* pp. never contains the whole of these metals; part passes into solution, and ultimately finds its way into the '*protoxide filtrate.*' In addition to its normal components it is liable to contain sulphide of zinc, and perhaps traces of other iron-group metals, and any cadmium, antimony, &c., that may have been allowed to slip into the filtrate from the sulphuretted hydrogen pp.

[2] If the solution contains *uranium*, this, in our scheme of analysis, goes with the iron, and consequently has to be looked for in the *sesquioxide* pp.; from which it can be extracted by digestion with warm, concentrated, solution of carbonate of ammonia. To pass now to a number of rare metals, which we have so far entirely ignored:

Palladium, in our system, belongs to the copper-group. It is characterised chiefly by the utter insolubility and black colour of its iodide.

Platinum and gold go into the arsenic group; only the sulphides are not easily soluble in alkaline sulphides. In almost all practical cases they can be kept outside the solution intended for the detection of the metals by suitable methods. If they are unavoidably present, they are best separated out; the gold by ferrous chloride (as metal); the platinum, by means of *solid* sal-ammoniac added to the concentrated solution, as $PtCl_6(NH_4)_2$, which must be washed with the least possible quantity of a solution of the precipitant.

Titanium, as TiO_2, in the analyst's sense stands between SiO_2 and Al_2O_3. In our system it goes with the Al_2O_3.

Beryllium behaves to our group-reagents like Al_2O_3, but it is far more easily soluble in sal-ammoniac than alumina is. Unlike it, it dissolves in carbonate of ammonia, and does not form an alum.

The rare earth metals, cerium, lanthanum, &c., &c., must all be passed over here.

Lithium (easily detected by spectrum analysis) behaves on the whole like K and Na, but unlike them forms an insoluble phosphate producible by evaporating its solution with phosphate of soda plus caustic soda (*i.e.* with Na_3PO_4), to dryness, and treating the residue with water, when it remains. From magnesia (if ammonia salts are absent) it

sent) is best analysed by fusion with caustic potash and nitre in a silver dish, and treatment of the fused mass with water. Should the solution be green from manganate, this must be reduced (to MnO_2) by addition of a few drops of alcohol and heating. The mixture is then filtered. The *filtrate* contains the chromium as (yellow) chromate, the aluminium as aluminate, and part, in general, of the phosphoric acid as phosphate. The *residue* contains oxide of iron, magnesia (MgO), and possibly barium-group metals as phosphates.

The Determination of the Non-Metallic Components.—Our systematic methods for the detection of the metals contained in a solution of salts are far less hampered by onerous conditions than are most of our methods of acid detection. Hence the general rule to first complete the analysis for metals before attempting the systematic and exhaustive search for the non-metallic components. How far the solutions obtained in the disintegrations are available for the latter purpose, and the respective methods of procedure generally, depend chiefly upon whether we merely aim at the detection of the non-metallic elements as such or at that of the acid radicles contained in the substance. All we could say in regard to the former case is anticipated in the section on the '*Detection of certain elements, &c.*' (p. 217) and the latter is not susceptible of being treated instructively in general terms. In regard to it we must refer to the special hand-books.

Quantitative Analysis.

The general problem of quantitative analysis defines itself. Its solution, scientifically at least, assumes its simplest form, if the thing to be analysed is given as a free substance and the (let us say *one*) component to be determined can be separated out exhaustively in the form in which it is meant to be reported. In such a case all that is required, in addition to the analysis proper, is the numerical definition of the two quantities concerned. Of the several direct methods which we have for this purpose, only two need be mentioned; one is to measure the *volume* of the body under stated conditions of temperature and pressure, the other is to determine its *weight*. The former method is confined in practice to gases and liquids; the latter is applicable, and indeed is applied, to bodies of all kinds, and, when we have choice, applied preferably. The volume of a body is a function of temperature and pressure, and its numerical statement is consequently encumbered with the necessary reference to—in general—two corresponding standards; the weight of a given body depends only on the intensity of gravity, and even this variable in practice is out of court, because, in chemistry we always use that well-known method of relative weighing which measures the weight of the body not in terms of a unit-force but as a multiple of the weight, at the time and place, of an adopted standard mass, viz. the unit-piece of our set of weights. The result of such a weighing is independent of the prevailing force of gravity, and consequently not subject to any variation; it consequently, at least, *indexes* the mass with perfect definiteness. We, moreover, know that it is independent of any chemical change within the body (or set of bodies) weighed. A mass of, for instance, sulphide of copper weighs precisely as much as the two components did conjointly. Hence for chemical purposes our method of weighing might safely be viewed as a method of true mass-measurement, even if Newton had not proved that equal weights (chemically determined) correspond to equal *inertias*.

The method of direct quantitative analysis explained is the only one which suggests itself when the component to be determined is a chemically indefinite mixture (such as for instance the mixture of salts contained in a natural water); it applies to a good many other cases; but of course breaks down whenever the body to be determined is an imaginary radicle such as SO_4 or ClO_3, &c. In such cases (and many others as a matter of expediency) we determine the component by one or other of our indirect methods of mass measurements; which, however, all come to this, that instead of the unknown mass x, we measure some other quantity q, which bears to x a known fixed relation, $x = f(q, m)$, where m is a mass which must be measured directly, although the analyst does not always do this at the time, or himself at all.

Most of our determinations in analysis are uncertain by at least 0·001 of their values, and a higher degree of relative precision is afforded by any fair ordinary balance. But the nature of our methods compels us, in general, to work on small quantities—we rarely care to start with more than one gram of a given solid—and besides the products to be weighed can in most cases not be placed on the bare pan, but must be shut up in apparatus weighing perhaps 100 or 1000 times as much as themselves. The net weight then comes to us only as a small difference between two large weights directly determined. So it comes that even for the ordinary routine of quantitative analysis, we need a balance which to be generally useful should carry about 100 grams on each side, and with this charge turn distinctly with anything greater than, say, 0·2 milligrams.

The Chemical Balance.[1]

In its present form the chemical balance is nothing more than a refinement upon the ordinary beam and scales to be seen in any grocer's shop; it is a more perfect realisation of the same ideal machine. There is an absolutely rigid beam, suspended so that while it oscillates freely about a certain axis, every *point* of which is *fixed* in reference to the stand, it cannot perform any other motion. From two points which lie in the same plane with the axis of rotation—one A near the left, the other B near the right, end,—the pans are suspended by means of absolutely flexible linear strings. A and B are equidistant from the axis of rotation. The form of the (ideal) beam is arbitrary; so in

---

is separated by solution of baryta in a warm liquid which pps. only the magnesium as $Mg(OH)_2$.

Rubidium and cæsium, in any scheme of analysis, follow potassium to the end.

[1] Partly abstracted from the writer's memoir: *Ueber die Waage des Chemikers* (*Zeitschrift für Instrumentenkunde*, 1881, 313 *et seq.*).

a sense is its mass, which, however, must be so distributed that, supposing the line A B to be horizontal, the centre of gravity of the empty beam lies vertically below, though very near, the axis of rotation. Let us at once add that in the actual instrument the weight of the beam should be no greater than is necessary to ensure to it sufficient stability of form in all circumstances, because the greater the weight of the beam, the greater (*cæt. par.*) the friction in the axis of rotation, and the greater the time of vibration.

Of the difficulties involved in realising the ideal machine, that of producing a light and yet practically inflexible beam seems to have rested most heavily upon the minds of the earlier makers; but there can be no doubt that many of their efforts in this direction (which occasionally resulted in what we should now call fantastical beam forms, such as hollow ellipsoids or double cones, monstrous skeleton forms, &c.) must be traced back to their inability to reach a sufficient degree of precision in the geometric adjustment of the three pivots, and their thus charging against the flexibility of the beam what was really owing to these defects in the adjustment. As these difficulties were overcome, beams assumed less fantastic forms. Sacré, of Brussels, we believe, never uses any but plain rod-shaped beams for even his finest instruments; most balance-makers, however, prefer the form of a largely perforated rhombus or flat isosceles triangle; and thereby attain all that is needful even for the best instruments without offending the eye by unduly stretching the maximum section, or without using anything more rigid, intrinsically, than hammered brass or some kind of hard bronze.[1]

In all modern balances the *axis of rotation* is sought to be realised in a straight knife-edge ground to a prism of hard material, which is firmly fixed to the beam traversing it cross-wise, and rests—in the best balances along its entire length—on a horizontal, plane, (and equally hard) bearing fixed to the stand. The arrestment is so contrived that, besides doing its primary duty, it secures to each point of the knife-edge a fixed position on its bearing whenever the balance works. In former times both bearings and knives used to be made of hard steel; subsequently agate bearings came to be combined with steel edges, and this is still the most popular combination; although Robinson long ago introduced agate knives in conjunction with agate bearings. The agate knife adds nothing to the precision or mechanical durability, but for laboratory balances offers the great advantage of rendering the system proof against acid-vapours; accordingly it is gaining more and more in popularity. Quite lately an American has introduced as a material for both knives and bearings that very hard (and acid-proof) alloy of osmium and iridium which is used for the tipping of stylograph pens.

The point pivots, A and B, used to be realised visibly by means of two circular knives fixed to the end of the beam so that their working-edges were parallel to the axis of rotation. From the lowest points, the pans were suspended by means of ? shaped hooks of steel wire. In this way a very high degree of precision can be attained, and the system when well executed is more durable than one would think, but with balances used for heavy charges it cannot possibly last for many years.

In the better system introduced by Robinson of London half a century ago each extremity of the beam is provided with a knife-edge similar to the central one (except that it is turned upwards); on each knife-edge rests a stirrup-shaped (or J-shaped) contrivance, terminating in a ring below, and from this ring the pan is suspended by a hook. This, of course, comes to the same as if the pan were suspended from the projection of the working point of the hook-and-eye arrangement on the respective knife-edge; so that the latter need not be absolutely parallel to the axis of rotation. Flat end-bearings demand a somewhat cumbrous and expensive appendage to the arrestment to secure to each point of every edge a fixed position on its bearing in the working instrument. Hence Staudinger, and many others, prefer to combine (long) end-knives with roof-shaped bearings, which, in virtue of their shape, fall into their prescribed positions without external aid.

In now passing from fundamentally important to subsidiary points, the *arrestment* ought to be taken up first; but we could not possibly do justice to this (practically all-important) subject without workman-like drawings and lengthy descriptions. We therefore pass on at once to the *needle* which serves to define the position of the beam in reference to the plumb-line.

In the precision-balance the needle is made to point downwards towards a scale fixed to the lowest convenient point of the pillar. The zero-point defines the 'normal position' of the beam, *i.e.* that position in which its centre of gravity lies vertically below the axis of rotation. The scale is so divided that the radii drawn from the axis of rotation through the marks divide the tangent to the circle described by the oscillating needle, at the zero point, into pieces of equal length, which in most practical cases means into degrees of equal angular value.

To avoid the use of small weights, each arm of the beam, in most balances, is divided into ten equal parts in the sense that the projections of the marks on the line A B connecting the two point-pivots divide the distance from the central pivot to (say) B into ten equal parts. A rider weighing ten mgms., when suspended on mark 1, 2, 3, &c., acts like 1, 2, 3, &c., mgms. placed on the pan. In most balances, however, points 0 and 10 are inaccessible. Becker's Sons, of Rotterdam, avoid this inconvenience by dividing each arm into twelve equal parts, and providing a rider of twelve mgms. weight. Some makers make the top bar of their beams straight, and exactly parallel to the plane of the three pivots, and let it project beyond the terminal edges, besides keeping it clear of encumbrances, so that the rider can move freely from one end of the beam to the other. This system, besides its obvious advantages, admits of the use of heavier riders; because the increase in sensibility caused by the presence of the rider is the same at any position which it may have; only the rider in such cases must be counted part and parcel of the instrument.[1]

---

[1] For further information regarding this question we refer to the writer's memoir quoted in footnote to p. 223.

In proceeding now to develop the statical theory of the precision-balance we will assume, for a first approximation, that the three pivots are physically and geometrically perfect in themselves, but, for the sake of greater generality, we will not assume that the knives are exactly in their intended positions. Imagine a system of rectangular co-ordinates fixed to the beam so that, while the z-axis coincides with the axis of rotation, the x-axis goes through the centre of the middle knife, and runs parallel to the line A B which joins the two point-pivots. Let the co-ordinates of A and B, of the centre of gravity S_0 of the empty beam, and of a certain point C to be defined presently, be as follows:

	A	B	S_0	C
$x =$	$-l'$	$+l''$	o	x_0
$y =$	$+h^*$	$+h^*$	s_0	y_0

Let P′ denote the total charge from A, P″ that from B, and W_0 the weight of the empty beam; the joint effect of these three weights is the same as if they were all concentrated in some point C at $x=x_0$ and $y=y_0$. For calculating purposes we may assume gravity in one case I. to act in the direction of the Y-axis, and in a second II. in the direction of the X-axis; we then have:

(Case I.) . $P''l''-P'l'=(P'+P''+W_0)x_0$. I.

(Case II.) $(P'+P'')h+W_0s_0=$
$$(P'+P''+W)(P'+P''+W_0)y_0 \quad . \text{ II.}$$

In any sensibly constructed balance things are so arranged that, under all circumstances that come into practical consideration, the centre of gravity C of the whole system lies outside and below the axis of rotation (*i.e.* that $y_0>o$). Assuming both x_0 and y_0 to have positive values, and the beam to be left to itself in its normal position, it will turn, and tend to assume that position in which C lies vertically below the axis of rotation. The radius OC then describes an angle equal to that which separates OC from the Y-axis, and obviously,

$$\tan. \alpha=\frac{x_0}{y_0}=\frac{P''l''-P'l'}{(P'+P'')hW_0s_0} \quad . \quad . \quad \text{III.}$$

To bring the equation into a handier form for our purposes, let us separate P′ and P″ into parts, thus; $P'=p'_0+p'$, and $P''=p'_0+p''$ where the p_0s stand for the weights of the empty pans, which are always so adjusted that $p'_0l'=p_0''l''$; let us then lump $p'_0+p''_0$ with the weight of the beam as $W=W_0+p'_0+p''_0$ and write

$$\tan. \alpha=\frac{p''l''-p'l'}{(p'+p'')+Ws} \quad . \quad . \quad . \quad . \text{ IIIa.}$$

where s has an obvious meaning. We then have for x_0 the equation

$$p''l''-p'l'=(v'+p''+W)x_0.$$

This equation may be said to state the theory of the ordinary method of weighing. To find the weight p' of a given body we place it on the left pan, and then try heavier and lighter combinations of standards on the right, until we have found out that one (representing p'' grams) which reduces x_0 to nothing, so that the balance is at rest at, or it vibrates about, its normal position. We then have $p'=\frac{p''l''}{l'}$.

In formulating the relation between a small overweight on one side and the corresponding angle of derivation α, we may take $l'=l''$ (as it really is very nearly in all well-adjusted balances), and (for $p'=p$ and $p''=p+\Delta$) write

$$\tan. \alpha=\frac{\Delta l}{Ws+2ph} \quad . \quad . \quad . \quad . \quad \text{IV.}$$

where α means the angle through which the position of rest turns in consequence of the addition of Δ units of weight to the right pan, the charge before having been $x=p$ on each side.

In practice tan. α is measured in degrees of the scale. Supposing α corresponds to n degrees of the scale, and the index-length is J in degrees, we have

$$\frac{n}{J}=\frac{\Delta l}{Ws+2ph} \quad . \quad . \quad . \quad . \text{ V.}$$

The ratio $\frac{n}{\Delta}$ defines the *sensibility* of the balance; we have for it

$$E=\frac{n}{\Delta}=\frac{l\,J}{Ws+2ph} \quad . \quad . \quad . \quad . \text{ VI.}$$

and for its reciprocal, $\frac{1}{E}$, the weight-value of 1° of the scale,

$$\frac{1}{E}=\frac{Ws+2ph}{l\,J} \quad . \quad . \quad . \quad . \text{ VII.}$$

For $h=0$, the term $2ph$ vanishes, and the sensibility becomes independent of the charge. In the actual instrument h is a function of the charge, of the form $h=h_0+\beta p$, where β is a small constant depending on the coefficient of elasticity and the configuration of the beam. For a given charge, a good maker has no difficulty in bringing h down to less than ±0·01 mm. The best instruments are so adjusted that, for a certain medium charge, $h=0$, so that for $p=0$ it has a small negative, and from $p=$ maximum charge a small positive, value. The relative change in the sensibility involved in passing from $p=0$ to $p=p$, is shown by the equation

$$\frac{E^{-1}-E_0^{-1}}{E_0^{-1}}=\frac{2ph}{Ws}$$

and consequently is the less (*cæt. par.*), the greater s, *i.e.* the less the initial sensibility, E_0. It (*i.e.* the left side of our equation) comes to its minimum (assuming p to represent the maximum charge) if the balance is so adjusted that, for the charge 0·83 p, $h=0$. Supposing this rule to be generally adopted, the relative inconstancy of the sensibility is independent of the arm-length (see the writer's memoir, p. 318).

No balance is complete without a ‘gravity-bob,’ a small button or sphere of metal attached to a wire which stands vertical on the top of the beam (in the Y-axis) so that it can be screwed up and down into any position. Matters are arranged so that when the bob is quite down the sensibility is below the lowest value we care for, while, by screwing up the bob to its highest place, we can bring C into, and even a little to the wrong side of, the axis [illegible] rotation. Hence it would appear that, by screwing up the bob sufficiently we can get our balance to turn visibly with say 0·001 milligram or anything less that we might care to name. So indeed it would be if our fundamental assumptions could be—and were—realised. In practice, however, the knife edges are *not* absolutely straight nor the bearings absolutely plane, and neither are absolutely rigid. Hence the three axes, instead of being always at $x = \mathrm{A}, o, \mathrm{B}$ respectively, so to say oscillate irregularly, each from $x - \lambda$ to $x + \lambda$, where x is the theoretical x. In going more fully into the matter we see that as a consequence the balance at a given charge (say p left; p right) is in a state of indifferent equilibrium within a small angle $\pm\beta$, which, of course, is the greater the greater is E. But the weight-value ϵ of this angle is constant, and is governed by *some* equation *like*

---

[1] For more exact information see the writer's memoir, page 322.

[*] + means ‘below x.’

$$\epsilon = \frac{\lambda}{l}(\mathrm{W} + 2p)$$

where 'λ' is meant to lump the joint effect of the three λs previously referred to. ϵ may be called the 'inherent error' of the balance. There is obviously no use in screwing up the bob any further than necessary to render this ϵ (*i.e.* angle β) distinctly visible. It may be inexpedient even to go so far, because, in practice, we never aim at the absolutely true weight, but at a value sure to differ from it by no more than say $\pm 0{\cdot}1$ mgm. The angle corresponding to this need not be more than distinctly visible. To make the angle greater than necessary needlessly adds to the time of vibration which may already be inconveniently high. Because the time of vibration (t in seconds) is governed by the equation

$$t^2 = \frac{l^2 \{ k\mathrm{w}_0 + 2(p_0 + p) \}}{R \{ \mathrm{w}_0 s_0 + 2(v_0 + p)h \}} \quad . \quad . \quad \text{VIII.}$$

where R denotes the length of the pendulum beating seconds at the place of observation. $k\mathrm{w}_0 l^2$ denotes the *momentum inertiæ* of the empty beam in reference to the axis of rotation. The denominator of eq. VIII. suggests the expression given in eq. VII. for the sensibility E. Combining the two we have

$$t^2 = \frac{l}{\mathrm{RJ}} \{ (k\mathrm{w}_0 + 2p_0) + 2p \} \mathrm{E} \quad . \quad . \quad \text{IX.}$$

The bob enables us to choose our own E. or our own t (for a named charge), but it does not enable us to choose both. We of course refer to a ready-made balance; in the hands of a mechanician who designs a balance for a stated purpose, l becomes an arbitrary variable, and the equation then assumes something like this form :

$$t^2 = l(\mathrm{c} + kbl + 2p)\mathrm{E} \quad . \quad . \quad . \quad . \quad . \quad \text{X.}$$

where c and b are constants whose meaning is sufficiently apparent. In words: Whatever (reasonable) value for E may have been fixed upon we can bring down t (for say $p = 0$) to any desired figure by making l sufficiently small. But where shall we stop? For high-class balances intended to weigh up to 100 grams, mechanicians used to draw the line at $l = 180$ to 200 mm. These values (perhaps more by dint of habit than on rational grounds) were retained until about twenty years ago, when P. Bunge, of Hamburg, introduced a new form of the instrument, in which the arm-length is reduced to some 60 to 65 mm. Thanks to the general excellence of Bunge's work, these short beams soon became very popular among both chemists and mechanicians; and it therefore is worth while to inquire what their specific advantages as short-beam balances amount to.

For this purpose the writer, some years ago, determined the constants of eq. X. for a very excellent Oertling (hectogram) balance, which he has in his possession, (its $l = 184$ mm.), and, taking it as a general model for an imaginary genus, calculated the values of t for a number of charges and sensibilities, assuming l to be equal to (*a*) 180 mm. and (*b*) 60 mm. He found for

I. $\mathrm{E} = 2$ *degrees of the scale per* 1 *mgm. of over-weight.*[1]

if $l =$	180 mm.	60 mm.
for $p = 0$; $t =$	7″·7	3″·6

The short beam obviously vibrates too fast for high-precision work. To set this right let us screw up the bob on both sides, so as to double the sensibility. We now have

II. $\mathrm{E} = 4$ *degrees per mgm.*

if $l =$	180 mm.	60 mm.
for $p = 0$; $t =$	11″·0	5″·2
as $p = 30$; $t =$	14″·8	7″·8
as $p = 100$: $t =$	21″·2	11″·6
$t_{100} : t_0 =$	1·93	2·23

The times of vibration no doubt assume the more convenient values in the shorter beamed instrument. But what does this amount to practically? In our opinion not to as much as some people seem to think. We are inclined to think that the short beam offers material advantages to those who are accustomed to the *dead-beat* method of weighing (see below). All those who prefer the method of vibration will on the whole, we think, fare better with the old form of the instrument. But this, to be complete, should be provided with the two following auxiliary contrivances of the writer's invention:

I. *An auxiliary small bob*[2] attached by mere friction to the upper part of the needle, which has the form of a triangular prism and is (virtually or actually) graduated, so that one is able, at a moment's notice, to give to the weight-value of 1° of the scale any convenient pre-determined value, to make it equal to exactly 2, 1, 0·5, 0·2 &c. mgm. as he may please.

II. *A microscopic arrangement*[3] for reading the excursions of the needle. A narrow ivory scale, divided into very small degrees, is fixed to the needle near its lower end, so that a microscope which is fixed slantingly to the stand but passes through the central (fixed) portion of the front pane enables one to read it. The microscope has a vertical wire in its focus; this wire appears as a vertical line crossing the image of the scale. Every degree of the micro-scale corresponds to exactly 0·1 degree of the ordinary scale, which latter does duty as usual. As the microscope reverses the image, the apparent motion of the 'wire' on the micro-scale is in the same sense as the real motion of the needle in reference to the ordinary scale, so that there is no fear of blunders through mistaking plus for minus. The writer is indebted to Mr. Oertling for having executed this arrangement for him in a most masterly manner. Though intended originally to be reserved for special work, such as weight-testing &c., it was found so convenient that both the writer and his assistants use it preferably for even their everyday weighings. The specific advantage of the microscope is that it enables one to adjust the 'bob' so as to produce the most convenient time of vibration. The microscope more than makes up for the involved loss of sensibility.

---

[1] *I.e.* the addition of 1 mgm. causes the needle to oscillate between 0 and ± 2°; 1° in the given instrument = 1 mm. very nearly.

On Weighing.

A precision-balance should stand on an unshakable table, and should not be exposed to the risk of one-sided elevation of temperature. Before being used for a series of weighings it must of course be set in order, which includes that the case be 'levelled,' so that the plane including the axis of rotation and the zero of the scale is a plumb-plane. The next thing to do (if necessary) is to bring the 'bob' into its proper position; *i.e.* to place it so that the least difference of weight we care for just becomes visible as an angle of deviation and no more, because to increase the sensibility beyond what is needful means needlessly to diminish the range of weights determinable by vibration, the constancy of the sensibility, and the rate of vibration. This rate of course must not be allowed to fall below a certain limiting value. In the writer's opinion, $t = 5''$ is about the lowest permissible limit for relatively heavy charges. Next, the balance must be brought 'into equilibrium' at least approximately. For this purpose Oertling's balances carry a vane at the top of the beam, consisting of a little lever hinged to the wire of the bob, which can be turned round, so as to shift the centre of gravity to the right or left.[1] A better arrangement is a small horizontal gravity bob at one end of the beam. For simplicity's sake we assume that the balance has been brought into perfect equilibrium, so that the needle in the vibrating instrument moves forwards and backwards between $+n°$ and $-n°$. To weigh an object (which, to fix ideas, we will assume to be a solid, and non-hygroscopic), the ordinary mode is to place it on the left pan, and then counterpoise very nearly with standard weights, say p grams, on the right. In order now to determine the small additional weight which is required to establish perfect equilibrium, we may use one or other of two methods. In the

Dead-beat method we simply continue our trials, until the needle vibrates about the zero as its position of potential rest. It is, however, hardly possible for any thinking person to use this method without at least instinctively combining it with

The method of vibration, which in its most exact form consists in this that we note down (at least mentally) the successive excursions of the needle, and from these calculate the position of rest. Supposing we count distances traced by the needle in moving from 0 to the left as positive, and those to the right as negative, and the needle turns successively at n_1, n_2, n_3, n_4, n_5, degrees, we have for the position of rest, 4 values,

$$\tfrac{1}{2}(n_1+n_2)\,;\ \tfrac{1}{2}(n_2+n_3)\,;\ \tfrac{1}{2}(n_3+n_4)\,;\ \tfrac{1}{2}(n_4+n_5),$$

and the mean of these four values gives the reading corresponding to the position of rest. But the factor $\frac{1}{2}$ can be dropped, because we are evidently at liberty to measure in half-degrees. By taking an odd number of readings we eliminate the error caused by what the needle loses in passing through its path; for ordinary practice 3 readings are sufficient. It suffices to determine $n_1 =$ (say) $+4{\cdot}2$; $n_2 = -1{\cdot}0$; $n_3 = +4{\cdot}0$, and compute 'α' = mean of $+3{\cdot}2$ and $+3{\cdot}0 = +3{\cdot}1$. In this case the right pan is too heavy by $3{\cdot}1 \times k$ mgms., if k is the weight-value of 1° at the respective charge. In a good balance k is almost independent of the charge; the writer's supplementary bob of course enables one to give it a pre-determined value. How k is determined need not be explained.

Supposing p grams to have established exact equilibrium, the object weighs

$$x = p\,\frac{l''}{l'}\ \text{grams.}$$

The several weights which enter the calculation of an analysis need only be relatively correct. Hence, if all the weighings involved are made on the same balance and with the same set of weights, and the objects are always in the left pan, in any such series we may adopt $\frac{l''}{l'}$ grms. as our unit and say $x = p$.

We do not consider it necessary to quote examples of cases in which as a matter of principle $\frac{l''}{l'}$ dare not be cancelled; we rather say that in all precision-balances worthy of the name $\frac{l''}{l'}$ is *very* small, not more than $0{\cdot}00005$ at the most. If the empty balance was in equilibrium at $+\alpha_0$ degrees we must add, if at $-\alpha_0$ degrees we must subtract, $\alpha_0 k$ mgms. from p.

Absolute Weighing.

Absolute precision-weighing in the chemical laboratory hardly occurs otherwise than in this sense that we may have to determine the weight of an object in terms of an *arbitrary* (but for this occasion absolute) standard. For this we have two methods.

I. *The Method of Substitution.* The object is placed in one pan of the balance, and counterpoised exactly by some suitable tare placed in the other. We then take off the object and put on standard weights until equilibrium is again established. If the method of vibration be used, the immediate result is the proof that the constant tare was balanced by (1) x grams of object plus δ grams, and (2) by $p+\delta_2$ grams of standards. Whence $x = p + \delta_2 - \delta_1$.

II. *The Method of Reversion.* After having brought the balance very nearly into equilibrium, we ascertain the number of grams which have to be placed in the opposite pan to exactly balance the object, once with the object on the left, and once with the object on the right, side. Assuming, for greater generality, that the right pan was from the first too heavy by δ grams, we have

---

[1] A vane with properly graduated limb is as good as a 'rider'; better in fact, inasmuch as it is not liable to drop off and get lost; this innovation was proposed by Hempel, but has not met with much favour as far as we know.

$$\text{I. } xl' = (p'' + \delta)\, l'' \text{ by the first trial.}$$
$$\text{II. } (x + \delta)\, l'' = p'l' \text{ by the second trial.}$$

Assuming for a moment that $l' = l''$ (as we always may if x is small), we obviously have $2x + \delta = p' + p'' + \delta$; or $x = \frac{1}{2}(p' + p'')$.

We will now drop this assumption, but assume that δ is so small that the balance cannot distinguish between $\delta l'$ and $\delta l''$; then we may write as

$$\text{I. } (x - \delta)\, l' = p''l''.$$
$$\text{II. } (x + \delta)\, l'' = p'l'.$$

Whence, by multiplication,

$$p'p'' = (x - \delta)(x + \delta) =$$
$$x^2\left(1 + \frac{\delta}{x}\right)\left(1 - \frac{\delta}{x}\right) = x^2\left(1 - \frac{\delta^2}{x^2}\right).$$

It is always possible to make a guess at the maximum value which $\frac{\delta^2}{x^2}$ could possibly have; supposing $\delta = \pm 0{\cdot}001$ grm. and x (*i.e.* p' or p'') = about 10 grms. $\delta^2 \div x^2 = 1 \div 10^8$ and can be neglected. In practice we take care not to allow δ to assume a greater relative value, and compute by $x^2 = p'p'$ or $x = \sqrt{p'p'}$, for which expression we may substitute $\frac{1}{2}(p' + p'')$, if p' and p'' differ by less than, say, p mgms.

On Sets of Weights.

A set of weights to be fully on a par with a given balance must be so exactly adjusted that no combination of the several pieces which can ever occur is wrong by more than the inherent error 'ϵ' (*v. supra*) of the instrument. This means that chemical weights, to be properly adjusted, require a balance of a very high order. But even the most perfectly adjusted set is of no permanent value unless the substance that it is made of offers a sufficient guarantee for constancy of mass. Of all available materials, rock-crystal comes nearest perfection, but it is difficult to work and bring into a handy shape. Of metals, Mr. George Matthey's ten per cent. iridio-platinum is the best; it is absolutely proof against even acid fumes, and sufficiently hard to be proof against abrasion by reasonable usage. Next after it comes 'hard' platinum (the slightly iridiferous metal of which crucibles are generally made); pure platinum is too soft. Brass, bronze, German silver, and other cheap metals are mere apologies for what ought to be used; yet these are used (in a sense unavoidably) for making the larger pieces in sets for every-day use. Gilding affords no protection against atmospheric influences, unless the noble metal is laid on thickly; a good lacquer is better than the film of gold which is customarily put on by electrolysis.

In constructing a set of chemical weights, we might choose our own unit, but whatever unit we might fix upon, any other mode of subdivision or multiplication than the decimal mode would be absurd; and there is no reason why we should not adopt some legally fixed and universally obtainable unit as *our* unit. The gram is used by chemists all over the world, almost to the exclusion of any other unit.

Sets of weights exact enough for all practical purposes can be had in commerce. Whoever may be the maker, a set of weights should not be used without having first been tested and found correct, at least in a relative sense. To show how the errors in a given set can be determined, let us assume for a while our set comprised only the pieces $(1)_0$, (1), (2), $(2)_1$, (5), (10) grams, and adopt these bracketed numbers as symbols for the unknown true weights. As a unit for the errors to be determined, we will adopt the 1 milligram as determined by a given rider of 10 mgm. weight; the $(1)_0$ shall serve as our provisional unit for the values (1) (2) (10). To determine (1) we compare it with $(1)_0$ by the method of substitution or reversal, and note down the difference between the two in terms of 'the milligram,' as determined by the method of vibration. We then compare $(1)_0 + (1)$ with (2); then (2) with $(2)_1$, &c., &c., to establish the following equations:

$$\begin{array}{lll}
(1) & = (1)_0 + \delta_1 & \text{mgms.} \\
(2) & = (1)_0 + (1) + \delta_2. & \text{,,} \\
(2)_1 & = (2) + \delta'_2. & \text{,,} \\
(5) & = (2) + (2)_1 + (1)_0 + \delta_5. & \text{,,}
\end{array}$$

$$\begin{array}{llr}
 & & \textit{Computed.} \\
(1) & = (1)_0 + \delta_1 \quad . \quad . \quad . & (1)_0 + \Delta_1 \text{ mgs.} \\
(2) & = 2 \times (1)_0 + \delta_1 + \delta_2 \quad . & 2 \times (1)_0 + \Delta_2 \text{ ,,} \\
(2)_1 & = 2(1)_0 + \delta_1 + \delta_2 + \delta'_2 \quad . & 2 \times (1)_0 + \Delta'_2 \text{ ,,} \\
(5) & = 5(1)_0 + 2\delta_1 + 2\delta_2 + \delta'_2 + \delta_5 & 5 \times (1)_0 + \Delta_5 \text{ ,,} \\
(10) & = 10 \times (1)_0 + \text{ \&c.} \quad . & 10 \times (1)_0 + \Delta_{10} \text{ ,,}
\end{array}$$

To know what the values $n \times (1)_0$ really are in terms of an adopted gram (say the true gram) we must compare one of the pieces, or a combination of some or all, directly with the corresponding standard weight. Supposing this had been done with the 10 gram piece, and this piece had been found free of error, we have $10 \times (1)_0 + \Delta_{10}\text{mg.} = 10\,\text{g.}$ (meaning 10 true grams)

$$\therefore (1)_0 = \frac{10\,\text{g.} - \Delta_{10}\,\text{mg.}}{10} = 1\,\text{g.} - \frac{\Delta_{10}}{10}\text{mgs.}$$

and by substituting this value for $(1)_0$ in the expressions $n \times (1)_0 + \Delta_n$ we obtain the values of all the six pieces in the form

$$(\text{N}) = \text{N}\,\text{g.} + x\,\text{mgm.};$$

but our 'mgm.' is strictly speaking an arbitrary unit; we have no right, for instance, to say

$$(5) = 5\,\text{g.} + \frac{x_5}{1000}\text{g.}$$

What the true gram-value of the rider is can only be found by joining on to our gram set a set of deci- and centi-grams comprising that rider, and determining their values by establishing the equation:

$$\begin{array}{ll}
(\cdot 01) & = (\text{rider}) + \delta_1, \\
(\cdot 02) & = (\text{rider}) + (\cdot 01) + \delta_2, \text{ \&c. up to} \\
(1)_0 & = (0{\cdot}5) + (0{\cdot}2) + (0{\cdot}2)_1 + (0{\cdot}1) \text{ \&c.}
\end{array}$$

and thus finding out the value of the rider in terms of g. But in practice the rider as a rule does not differ much from ·01g., and this part of the work is not necessary for the sake of the calculation of the errors, the less so as a great value in any of these would simply condemn that piece.

The above method is always used when we test a set of weights with the view of seeing how it falls in with the rest of the sets in the laboratory, which in the aggregate form our set for general purposes. If the set is meant to be used by itself—if, for instance, we test a set from 50 grms. down to 1 centigr. with the view of using it for our analyses—it is better not to refer to any external standard at all, but to an imaginary unit so chosen that the sum total of the errors becomes nil, *i.e.*, to choose as unit $\frac{1}{100}$ of the actual weight of all the '100 grams' which the 50 gram set represents *in toto*. If one or more of the pieces come out with relatively large errors, the unit is re-adjusted so that it suits only the good pieces, the errors are re-calculated, and the two rejected pieces either replaced by new ones, or re-adjusted. According to the writer's experience, we must be satisfied if the errors of the individual pieces are brought down to values varying from very little to about ± 0·04 mgm.

Reduction to the Vacuum.

All weighings executed in air are liable to an obvious correction. Supposing an object occupying V c.c. is balanced in air by p grams of standards occupying v c.c.; if the balance were transferred to a vacuum, the side of the greater V (in our case the object side) would become heavier than the other by $(V-v)\,\delta$ grms. where δ is the weight of one c.c. of air at the time and place. As p is a close approximation to the true weight, the volume of the object in c.c.s can be put down as $p \div S$, that of the standards of course *is* $p \div S_0$, where S and S_0 are the respective specific gravities which practically need not be reduced to water at 4°. The correction to be applied to p is

$$p\delta\left(\frac{1}{S} - \frac{1}{S_0}\right),$$

$$\delta = 0{\cdot}46464\,\frac{B}{273+t}\,(\text{mgms.}),$$

where B is the height of the barometer in mm. reduced to 0°C., and t is the temperature; the constant is calculated from Regnault's weight of 1 litre of air of 0° and 760 mm. at London.

For $t = 15°$, and $B = 760$ mms., $\delta = 1{\cdot}22615$, which number, at stations where B is habitually near 760, if the highest precision is not aimed at, may often be taken as holding for air generally.

Standard weights for absolute weighings (in true grams) ought to be adjusted for the vacuum; hence, if the minor weights are of platinum and the larger ones of brass, the brass 1 grm. should appear lighter than its equivalent in platinum decigrams in air. But sets of this order had better be made of one metal.

For a series of relative weighings, the buoyancy of the weight-standards in air may be neglected, because we are at liberty to take as our unit the weight of the 1 grm. piece in air of the average density prevailing during the progress of the experiments. That this unit is strictly speaking variable is of no practical significance.

The vacuum-correction for any single weighing involved in an analysis amounts as a rule to more than we should care to neglect; yet it may be neglected in most cases, because the weight to be determined is only one term of a ratio, whose other term is faulty in the same sense. Suppose we have determined two weights, p_1 and p_2, and we want the correct value x of the ratio of which $p_1 : p_2$ is only an approximation. If the reciprocals of the specific gravity are S_1^{-1} and S_2^{-1} respectively, we have

$$x = \frac{p_1}{p_2}\;\frac{(1 + \delta_1 S_1^{-1})}{(1 + \delta_2 S_2^{-1})};$$

or as a sufficient approximation

$$x = \frac{p_1}{p_2}\;(1 + \delta_1 S_1^{-1} - \delta_2 S_2^{-1}).$$

And if S_1 does not differ much from S_2 (as δ_1 and δ_2 are always nearly the same) the bracketed factor may come close to unity although neither of the two terms $S^{-1}\delta$ could be neglected if it stood by itself. Here, as everywhere in experimental science, the golden rule is neither to strain at the gnat *nor* to swallow the camel.

Weighing of Gases.

For the weighing of a gas, we have in general three methods.

(1) If the gas to be weighed is a product formed in a reaction between solids or liquids, we may identify its weight with the loss of weight suffered by the reagents during the reaction.

(2) We may collect the gas in a evacuated tared balloon, and weigh it like anything else. In this case it is expedient to tare the flask with another flask of the same displacement and nearly the same weight, so that only a few grams need be put on to establish equilibrium. (Regnault's method). The vacuum-correction is then out of court.

(3) We may measure the gas by volume at a known temperature, t, and pressure, P, and calculate the weight from the volume.

If the gas to be weighed is a product of a reaction carried out quantitatively, one way of measuring it is to construct the apparatus so that the vessel in which the reaction goes on and the gas-measurer have a common atmosphere, and to measure the gas-volume as an increase in the total atmosphere of the apparatus (gas-volumetric method). According to Regnault, 1 lit. of oxygen at 0° and 760 mm. of mercury of 0°C., weighs 1·42932 grams. Hence by an easy computation, based on Avogadro's law, we have for the weight of 1 litre of a given species of gas of the molecular weight M (O = 16)

$$D = 0{\cdot}032089\,\frac{P}{(273+t)} \times \frac{M}{2}\,\text{grams}$$

where P means the dry pressure in mm.

If the gas is moist, the vapour-pressure of steam at $t°$ must be deducted from the observed pressure to find the D of the formula. The constant, strictly speaking, holds only for places where gravity is the same as it is at 45° latitude, and sea-level.

In *Paris*, | *London*, | *Berlin*, | *Glasgow*,
it must be multiplied by
1·000333, | 1·000583, | 1·000663, | 1·000956.

Indirect Methods of Mass Measurement.

I. *Physical Methods.*

The nature of these is best explained by a general example. In a given aqueous solution of sulphuric acid, sugar, salt, &c., &c., the specific gravity at $t°$, the refractive index, the power of turning the plane of polarised light (if any), &c., bear each a fixed relation to the percentage of substance (or the weight of substance per litre) in the solution, which relation is susceptible of translation into a formula $p = f$ (physical property), or a corresponding curve, and by means of either of tabulation. Hence, supposing the function to have been determined by standard experiments, p in a given case can be calculated (virtually or actually) from the value of the respective physical property. In practice we must of course try to establish conditions under which the change in the specific gravity, &c., &c., corresponding to the passing from p to, say, $(1{\cdot}01)\,p$, assumes a sufficiently great value.

The popular method for determining the strength of aqueous oil of vitriol, &c., by means of a hydrometer may be referred to as an example. The customary method of deducing the percentage of sugar in a syrup from the angle through which a column of given length turns the plane of polarised light is another.

II. *Chemical Methods.*

These, being all founded upon our knowledge of the quantitative laws of certain reactions, are methods for the indirect weighing of radicles rather than of substances. Scientifically one might arrange them according to their degree of directness. If we do so, the following two claim precedence before any of the rest.

(1.) *The direct gravimetric method.* An unknown weight of this or that radicle is determined by separating it out exhaustively, by itself or as part of a compound of known composition, and weighing the product either directly on the balance, or perhaps indirectly by gasometric measurement.

(2.) *The method of titration.* An unknown weight of radicle is deduced from the quantity of reagent necessary and sufficient to cause it to undergo a certain definite change of combination; the quantity of reagent being ascertained synthetically, *i.e.* by direct trial.

These two methods we will designate as 'direct' methods in opposition to the following 'indirect' methods.

(3.) *The method of substitution.* Instead of determining a radicle R, we substitute for it an equivalent of some other radicle (or substance) R′; we determine R′ by method I. or II., and from it calculate R. Thus, to determine an unknown weight of free chlorine, $x\,Cl_2$ mgms., we substitute $x\,I_2$ mgms. by means of the reaction $Cl_2 + 2KIAq = 2KClAq + I_2Aq$, and determine the iodine. In some cases we effect a series of substitutions (R′ for R; R″ for R′; R‴ for R″, &c.), and determine only the ultimate substitute. Thus, to determine $x\ CrO_3$, we substitute first $x \times 3Cl$, then for this we substitute $x \times 3I$, and by ascertaining the value $x \times 3I$ we find $x \times CrO_3$.

(4.) *The residue-method.* The body containing the radicle is subjected to a definite chemical change by means of a known (excessive) weight of reagent, and the excess of reagent left is determined.

(5.) *Methods founded upon the numerical difference between formulæ-values*:—We pass at once to examples:—

(*a.*) To analyse a mixture of the compounds AgCl and AgBr, we expose a known weight to the action of dry chlorine until all the AgBr has become AgCl, and determine the decrease of weight involved. From the obvious equation of the reaction, we see that every Br-Cl gram of loss of weight corresponds to Br grams of bromine, or AgBr grams of bromide of silver.

(*b.*) To determine the weight of real sulphuric acid contained in a given quantity of an aqueous acid, we evaporate with a known (excessive) weight of anhydrous carbonate of soda, and weigh the residue (Thorpe). As $x\,Na_2CO_3 + Na_2CO_3 + H_2SO_4 = CO_2 + H_2O + Na_2SO_4 + xNa_2CO_3$, every $(SO_3 - CO_2)$ grams of increase of weight indicate SO_3 grams of sulphur trioxide.

(*c.*) To analyse a mixture of the sulphates of sodium and lithium; take p grams of the mixture, ppt. all its sulphuric acid with barium chloride, and weigh the barium sulphate.

1 grm. of the sodium salt gives $\frac{BaSO_4}{Na_2SO_4} = s$,

1 grm. of the lithium salt gives $\frac{BaSO_4}{Li_2SO_4} = l$, grms

of barium sulphate. Hence if c grms of pp. were obtained we have (from x grms of sodium sulphate, and y of lithium sulphate)

$$x \times s + y \times l = c$$
$$x + y = p.$$

Whence x and y are easily calculated.

Many other examples might be quoted.

We will now pass to

The Operations involved in quantitative determinations by chemical methods. But first let us say a few words about a necessary preliminary to any quantitative analysis, namely, the preparation of the sample. This problem assumes perhaps its most difficult form if the thing to be analysed is a large mass of imperfectly homogeneous matter, say, a cargo of copper ore. In this case the analysis must of course be preceded by the preparation of a sample, which, although it may amount to only a few pounds, yet can be assumed with a sufficient degree of probability to have the composition of the whole heap. And supposing even a homogeneous sample to have been prepared for the analyst, a mere assay (of the copper in our case) would be of no use unless accompanied by determinations of the moisture in, *a* the ore as it lies, and *b* the small ultimate sample which goes to the balance. An impure specimen of a named chemical species to be rendered fit for the analysis of the species must first be purified, unless we prefer to determine the impurities, and allow for them in the calculation.

In now passing to our subject, we will give the first place to the operations involved in those

I. *Assays by igneous operations,*

which are so extensively employed in practical metallurgy. These, however, are quite a speciality which is almost entirely confined to metallurgical laboratories. Suffice it, therefore, to say that these *assays*, as the name indicates, are, at least by original intention, processes of metal-smelting carried out tentatively on a small scale. The metal is separated out as a regulus either of the metal itself or of some definite arsenide, and in either form is weighed directly on the balance-pan.

II. *Quantitative expulsion of volatile components by exposure of the substance to regulated temperatures.*

Under this heading fall most of our methods for the determination of *water*, given in combination with *non-volatile* residues. Water thus combined, can, as a rule, be driven out with or without the help of a dry atmosphere, by prolonged exposure of the substance to a suitable temperature, and, if other changes are known not to take place, the weight of the water expelled is the loss of weight involved in the drying process.

If the residue, while giving up its water, takes up oxygen or suffers some other change involving change of weight, the water must be expelled in an apparatus so constructed that the steam can be purified (if necessary) and collected without loss by absorption in a weighed U-tube filled with chloride of calcium, or pumice moistened with sulphuric acid, and determined as an increase of weight of the absorption apparatus. We have no means of discriminating experimentally between water present as such (moisture) and water present in chemical combination;[1] nor can we discriminate analytically between the different states of combination which we distinguish in our formulæ. All the analyst can do (after removal of what there may be of palpably free water by mechanical means) is to try, successively, exposure to (1) ordinary 'dry' air; (2) artificially dried air, or a dry vacuum; (3) a graduated series of higher temperatures, such as 100°, 120°, 150°, 200°, in a hot air chamber; (4) a red or perhaps a white heat; and to report the several losses of weight, taking care of course to apply each temperature again and again, until the weight of the residue (or of the calcium chloride tube) has become constant.

From hydrates undecomposable by mere heating, the water must be expelled by suitable reagents. Basic hydrates, like caustic potash, can be dehydrated (quantitatively) by fusion with excess of anhydrous bichromate of potash; many hydrated acids, by evaporation of their solutions with a known excessive weight of oxide of lead, and weighing the dried residue. The writer directs attention to the applicability of tri-sodic phosphate as a weighable form of Na_2O for the latter purpose.

III. *Combustions in glass tubes*, v. ANALYSIS, ORGANIC.

IV. *Carius' general method of ultimate organic analysis*, v. ANALYSIS, ORGANIC.

V. *Gas evolutions.*

We here refer to a class of methods in which the thing to be determined is measured by the weight of a gas evolved in a wet-way reaction of the substance to be analysed. The gas evolved is weighed as loss, or after absorption by a suitable absorbent, or is measured (and thus indirectly weighed) gasometrically (*v. supra*).

VI. *Electrolysis.*

Solutions of many heavy metallic salts, when subjected to a galvanic current under suitable conditions, are fully decomposed, in the sense that all the metal separates out as such on the negative electrode. By properly regulating the strength of the current and the composition of the liquid, it is possible, in many cases, to cause the whole of the metallic pp. to assume the form of a coherent, truly metallic, deposit, so that, if a platinum electrode be used, the metal can be determined as an increase of weight of the latter. The method, however, is not as easy as it is obvious; and is in general use only for two metals, namely copper (Luckow's method), and nickel. Classen[1] has tried, not without success, to extend the method to many other heavy metals; but his processes have failed so far to become popular.

VII. *Gravimetric Precipitation.*

Our heading refers to the very large number of cases in which we determine a component of a solution by separating it out in an insoluble form, and weighing the pp. or converting it into another body and weighing that. With the preliminary separations that may be necessary we can have nothing to do here; we assume that the ppn. has been effected exhaustively, and that the pp. is (in the sense of the method) free from foreign components. In this case the next thing to be done of course is to separate the pp. completely from the mother-liquor. In some cases (for instance in the case of the haloid salts of silver, and of metallic gold ppd. by ferrous salt) this can be done by decantation; but as a rule it is necessary to resort to filtration. For this operation the first requisite is a good funnel, and good filter-paper. The funnel should be a smooth cone of exactly 60° aperture, so that a filter folded in quarto fits it exactly. The best filter-paper for general purposes is that Swedish paper known as Muntkell's; only it filters somewhat slowly, and in many cases, therefore, papers of looser texture are preferable. Filters, which, having been washed with hydrofluoric and hydrochloric acids, leave almost no ash on incineration. In conducting a filtration, the following rules should be observed:

1. Before starting the filtration, allow the pp. to settle completely; then decant off the liquor on to the filter, allowing as little of the pp. as possible to go on to the paper.—2. The same rule holds for the first stages of the washing process; the bulk of the pp. should go on to the filter only after almost all the dissolved matter has been washed away.—3. The wash-liquor should be employed in small instalments, and each instalment be allowed to drain off, before the next one comes on.—4. The washing must be continued until the purity of the last runnings is proved by direct testing. No calculation of the attenuation reached can be relied on implicitly, although it is valuable for preliminary guidance, and may be the only method

---

[1] According to the current notions on dissociation, a current of (originally dry) air which has passed over a sufficient column of partially dehydrated salt, should take away the free water from a given specimen of *moist* salt of the same kind at the same temperature. Hence an obvious (theoretical) method for recognising free water as such.

[1] Classen: *Quantitative Analyse durch Electrolyse.* [2nd ed. Berlin, 1886.]

available.—5. The filter should fit the funnel closely; it should be smaller than the funnel, and not much larger than is necessary for the convenient accommodation of the pp.

Many pps. run through the paper as soon as the wash-water becomes nearly pure; bisulphide of tin exhibits this property in a marked degree. Addition of some suitable salt (sal-ammoniac, acetate of ammonia, &c.) to the wash-water often helps one over this difficulty.

In the case of slimy or gelatinous pps. (*e.g.* hydroxides of silicon, aluminium, and chromium) Bunsen's method of quick filtration is employed. It consists in this, that the funnel is made to communicate, by its stem, with a vessel in which a partial vacuum of adequate strength is maintained by means of an aspirator (a Sprengel pump wrought with water, or equivalent arrangement). To protect the filter from being torn by the pressure of the atmosphere, its open end is supported by a small cone of platinum foil, resting on the bottom of the funnel. In regard to the operations subsequent to filtration and washing, pps. may be classified as follows:—

A. Such as stand calcination in a platinum or porcelain crucible, and when thus treated assume a definite composition. In this case the general *modus operandi* is as follows: the pp. is dried in the funnel; it is then detached as completely as possible from the paper, and put into the tared crucible. The filter, with adhering particles of pp. is folded up into a narrow strip, and this is rolled up tightly into a parcel, so that the part stained with the pp. is in the core. A platinum wire is then wound round two or three times, and the parcel is kindled in a gas flame and allowed to burn, the surplus wire serving as a handle. After the combustion has gone as far as it will spontaneously, the residual charcoal is burned away by applying the outer portion of the flame of a Bunsen. The ash is dropped into the crucible and calcined along with the pp. In some cases, as for instance in that of alumina, it is better not to detach the pp. from the filter, but simply to fold up the pp. in the filter, and heat the whole in a platinum crucible. Any deposit of charcoal formed on the lid or crucible sides is easily removed by heating the respective part while a shield of platinum foil is stretched over the deposit. The charcoal vanishes almost instantaneously. The weight of the filter-ash must of course be ascertained by a blank experiment, and allowed for. The correction (*cæteris paribus*) is proportional to the superficial area of the filter; *i.e.* ash-weight $= cr^2$, where c is a constant which can be determined once for all.

It is to be observed, however, that even with the same filter-paper, c depends on the nature of the liquid which passed through the filter. It is less for dilute mineral acid, for instance, than for pure water, or salt solutions followed by water.

B. Precipitates which do not stand calcination; but assume a definite composition when dried at a suitable lower temperature, say at 100° or 120°C. Such pps. are collected on filters (previously dried at the respective temperatures) and weighed in the filters. As filter-paper is hygroscopic, the empty filter, and the filter with pp., must be weighed between a couple of closely fitting watch-glasses held together by a suitable clip.

C. Precipitates which demand some supplementary chemical treatment to become fit for the balance. In regard to these it is difficult to make general statements; suffice it to say that certain metallic sulphides assume a definite composition when strongly heated (repeatedly, and until constant in weight) with sulphur in hydrogen gas. The sulphides of copper, manganese, zinc, lead, may be quoted as examples. The resulting definite sulphides are Cu_2S, MnS, ZnS, PbS, respectively.

GAS ANALYSIS.

A large supply of homogeneous gas may be dealt with, analytically, in a variety of ways. With a small gas-sample given for analysis only one mode of treatment could be—or at any rate ever is—thought of. We must collect our gas over mercury, or some other suitable liquid, and learn what we can concerning it by applying physical or chemical reactions, involving changes of gas-volume; we must measure the gas volumes involved as the only practicable mode of defining the respective masses.

Principles of volumetric gasometry. To measure a given quantity of gas means to determine its volume, V, and its pressure, P, at a definite temperature, t. In any *fluid* body of known nature the three quantities conjointly define the mass; yet the method is confined to gases, because in these only is the evidence afforded by the three numbers condensible into *one* numerical statement by mere calculation.

Practical gasometry knows of no pressure greater than two atmospheres (indeed pressures above one atmosphere are exceptional); and of no temperature below 0°C.

Within this range of conditions the law of interdependence between volume, temperature, and pressure, in all gases is in approximate accordance—in the so-called permanent gases it is in perfect accordance—with the equation

$$\frac{VP}{T} = Q \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where T may be defined as $T = 273 + t$. Q is a constant which depends only on the nature of the gas and its mass, and consequently, in reference to any named species, measures the quantity.

Condensible gases and vapours deviate from the law embodied in eq. (1) to a greater or less extent, but always in this sense that the true relations are expressible by an equation of the form

$$\frac{VP}{T}(1 + \epsilon) = Q \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where ϵ is an inherently positive number which is a function of T and P, to the effect that, for any given species, ϵ is the less the further the pressure and temperature remove the gas from the state of saturated vapour. Gasometrically speaking ϵ is mainly a function of temperature which runs pretty much like $\epsilon = \text{const}'.\frac{1}{T}$; not by any means exactly so, but we are safe in saying that for every gas-species there is a certain temperature T_0 above which this species is, as the phrase goes, a 'perfect gas, in at least this sense that ϵ is less than the unavoidable error involved in the experimental determination of $PV \div T$ by the customary instruments. In this sense our equation (1) is true for all kinds of gas or vapour without exception.

The constant Q is obviously susceptible of a number of definitions. One definition is to call it the volume which the gas assumes when $T = 1°$ and $P = 1$ (say 1mm.), or rather the volume which the gas would assume if it were a perfect gas down to $T = 1$ or $t = -272°$. To eliminate this fiction, let us view V as a function, not of P and T, but of $\frac{T}{P}$, thus:

$$V = Q\left(\frac{T}{P}\right);$$

and, taking '*disgregation*' as a name for this ratio $T : P$, define Q as that volume which the gas assumes whenever the disgregation is unity through P being equal to T numerically. If, for instance,

$T = 1°$	273°	373°	500°C.	&c.
then $P = 1$	273	373	500 mm.	&c.

In this manner it is always easy to find for Q a *real* significance. Q, however, has two denominations. Obviously

$$P = Q\frac{T}{V},$$

hence Q may be called the particular pressure which the gas assumes whenever $T = V$; *i.e.* for $T = 1°$ and $V = 1$ unit; $T = 500°$ and $V = 500$, &c.

For the purely *comparative* measurement of two or more gas quantities, only one of the three variables need actually be measured.

Assuming the Qs for the gases I, II, III...to be Q' Q'' Q''', &c., we may (1) keep T and P at constant (though perhaps unknown) values and measure the volumes

$$\begin{array}{cccl} V' & V'' & V''' & \text{\&c. which are} \\ \frac{Q'T}{P} & \frac{Q''T}{P} & \frac{Q'''T}{P} & \text{\&c.} \end{array}$$

The constant factor disappears in the ratios. This used to be, at least by intention, *the* method of comparative gasometry.

(2) We may keep T and V constant and measure the pressures P' P'' P''' which are

$$Q'\frac{T}{V} \quad Q''\frac{T}{V} \quad Q'''\frac{T}{V} \text{ \&c.}$$

and consequently again measure the Qs (Regnault's method).

(3) We may allow T and P to vary, but keep their ratio, the *disgregation*, constant, and measure the volumes, *i.e.* substitute for the Qs

$$(Q' \quad Q'' \quad Q'''\ldots) \times \text{a constant } \frac{T}{P}$$

(Doyère's method).

But Q has an important chemical significance. A glance at eq. (1) shows that the specific gravity of a gas, meaning the number of times its weight is greater than that of the same volume of some standard gas of the same disgregation, is independent of T and P. As stated by Avogadro, and since proved by numerous experiments, we have for any set of gas-species

$$S' : S'' : S''' \ldots = M' : M'' : M'' \ldots\ldots$$

or quite generally

$$S = \text{const.}\, M \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where M is the mol. weight.

Hence supposing, at a given disgregation unit volume of standard gas weighs R units, then unit vol. of another gas of the mol. w., M weighs $R\frac{M}{M_0}$, where M_0 refers to the standard gas. Hence unit-volume of any gas, if measured at that disgregation, contains $\frac{R}{M_0} \times M$ units of weight of its substance; hence equal volumes of any two gases, if measured at the same disgregation, contain the same number of molecules, where 'molecule' *may* have the usual meaning given to this term. Hence our constant Q, or any of its substitutes as given above under (1) (2) and (3), in a relative sense counts the molecules of the respective gas.

Eq. (1) tells us nothing about the relation between the volume V of a gas-mixture, and the volumes v' v'' v'''...of its components; but we know, by direct experience, that $V = v' + v'' + v''' \ldots$;[1] hence Avogadro's law holds for mixed as well as for homogeneous gases; and, independently of it, we have

$$q' + q'' + q''' \ldots = Q \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and at any constant value of $V \div T$

$$p' + p'' + p''' \ldots = P \quad . \quad . \quad . \quad . \quad . \quad (5)$$

(where the small letters refer to the components and the large ones to the mixture). And so quite generally

$q : Q = v : V = p : P =$ (number of mols. in the component): (number of mols. in the mixture) . . . . (6)

Hence our customary mode of stating the composition of a gas-mixture is susceptible of three readings. Instead of saying (1) 100 volumes of air contain 21 vol. of oxygen and 79 of nitrogen; we may say (2) the partial pressure of the oxygen is 21 p.c. and that of the nitrogen 79 p.c. of the total pressure of the air; or (3) every $n \times 100$ mols. of air contain $n \times 21$ mols. of oxygen and $n \times 79$ of nitrogen.

In the more easily condensible gases, the number ϵ (which might be called the measure of gaseous imperfection) assumes appreciable values at the ordinary temperature; yet in the ordinary practice of gas analysis even these gases are customarily being measured at, or near, the temperature of the laboratory. To give an idea of the possible value of the error thus neglected we will take up the case of carbonic acid, which, of ordinarily occurring gases, is perhaps the most imperfect.

According to Amagat, carbonic acid, from 0°C. upwards, expands at a greater rate than air, up to about 200°, whence onward it behaves like a perfect gas in reference to expansion caused by changes of temperature or pressure. At 760° mm. its expansion from 0° to 200° is in the ratio[2] of 1 : 1·74065. Hence supposing we find for a quantity of carbonic acid $v = v_0$, for $T = 273$ and $P = 760$, we have for the constant Q:—

(1) By the ordinary routine mode of calculation, *i.e.* by eq. (1); $Q' = \frac{v_0 \times 760}{273}$;

---

[1] It is worth while to note that this all-important proposition has never been looked into in the Regnault-fashion.

[2] Calculated by the writer from the coefficients of expansion stated by Amagat for 50°, 100°, 180°, and 200°.

(2) For the true Q;

$$Q_0 = \frac{v_0 \times 1{\cdot}74065 \times 760}{273}.$$

Whence $Q_0 = 1{\cdot}0046\ Q'$; or in the sense of our equation (2), for $T = 273$ and $P = 760$ mm.

$$\Delta Q_0 = \frac{v_0 \times 760}{273}(1+\epsilon);\ \text{and}\ \epsilon = 0{\cdot}0016. \quad . \ (7)$$

This number, or say 0·005, might perhaps be put down as the maximum value which ϵ may assume in the customary mode of measuring gases proper, were it not for the following consideration. As a rule the gas to be measured is contaminated with vapour of water, and it is the Q of the *dry* gas that is wanted. One mode of obtaining it is to remove the water by chemical absorbents and to measure the dry gas; but this is a tedious process; hence we prefer, in practice, to saturate the gas completely with water, to measure it in this condition, and, before calculating by eq. (1), to correct the observed pressure by deducting the maximum steam-pressure at the respective temperature, as determined by Magnus and by Regnault for the vacuum, assuming the corrected value $P_0 = P - \pi$ to represent the pressure which the gas would exhibit at the same vol. and temperature if it were dry. As shown by Regnault, this is not quite exactly the case, yet if π is small, *i.e.* if the *temperature* is *low*, the error may be neglected. A low temperature, it is true, means a relatively great ϵ, but π certainly, and the error in π probably, increases (with t) much faster than ϵ decreases.

Both the authorities named give their πs in terms of the pressure of a column of mercury of 0°C. whose height equals 1 mm. Hence to be able to use their numbers directly we must provide our eudiometers and barometer with true mm.-scales. And we ought to reduce all mercury columns (measured as pressures) to 0°C. This, however, is necessary only in the case of absolute measurements, *i.e.* if we measure a gas as a step towards calculating its weight; for relative measurements we may choose our units for V, T, and P, at pleasure,[1] hence the absolute magnitude of our 'mm.' is of no consequence. Nor is it necessary to reduce the π to what our mm. is at the respective temperature, because the correction is practically irrelevant.

Gases like hydrochloric acid, ammonia, sulphur dioxide, &c., must be measured dry—for an obvious reason.

Gas-Analysis. (a) *Proximate.* For the proximate analysis of a gas-mixture we have only one direct method. After having measured off a convenient sample, we withdraw the several components (singly or in groups), by the successive application of appropriate chemical absorbents, as pressureless solids or liquids, and, after each absorption, we measure the gas-residue left. Supposing the sample measures V units at T and P, and the same, minus component I, measures V′ units at T′ and P′; we have for the sample $Q = \frac{VP}{T}$, for the residue $Q' = \frac{V'P'}{T'}$; hence for the percentage of I; $x = \frac{Q - Q_1}{Q} \times 100$.

To show the possibilities of the method, we enumerate the most important reagents and state the powers of each as an absorbent.

(1) *Water* (as such or as $Na_2SO_4 10H_2O$) absorbs HCl, HBr, HI, very promptly.

(2) *Solid* DRY *caustic potash* absorbs water very completely; acid gases generally more or less slowly.

(3) *Solid* MOIST *caustic potash* absorbs all acid gases (CO_2, SO_2, H_2S, HCl, &c.) very readily.

(4) *Caustic potash solution* acts like (3) and (1).

(5) *Dilute sulphuric acid* absorbs all alkaline gases (NH_3, CH_3NH_2 &c.); besides acting as water.

(6) *Oil of vitriol* ($H_2SO_4 + \frac{1}{12}H_2O$) absorbs (*a*) water, alcohol, ether, methyl-oxide, very readily; (*b*) propylene and higher homologues, with a fair degree of promptitude. C_2H_4 is absorbed only on long-continued shaking (Berthelot).

(7) *Sulphuric anhydride* in H_2SO_4 absorbs C_2H_4 in addition to the gases named in (6).

(8) *Bromine* (over water in diffused daylight) acts pretty much like (7); the excess of Br vapours left is removed by means of KHOAq.

(9) *Pyrogallic acid in caustic potash ley* absorbs oxygen abundantly and promptly (Liebig), besides acting like (4).

(10) *Cuprous chloride in hydrochloric acid* absorbs oxygen; also CO, C_2H_2, C_3H_4 (Bertholet).—Spoils the mercury.

(11) *Same reagent in aqueous ammonia* acts like (10), and besides absorbs certain other gases, *e.g.* all the olefines (Berthelot).

(12) *Ferrous sulphate in concentrated solution* absorbs nitric oxide; but hardly in the chemical sense, as the compound has a measurable dissociation-pressure.[1]

(13) *Binoxide of manganese*, as compressed powder, is used by Bunsen for absorbing H_2S and SO_2.—Solution of CrO_3 or of $KMnO_4$ acts similarly and more promptly.

(14) *Chromous sulphate in NH_3 and NH_4Cl solution* absorbs O, NO, C_2H_2, C_3H_4, but does not act on CO, C_2H_6, or C_3H_6 (Berthelot).

That all gas mixtures cannot be analysed by means of these 14 reagents is obvious. Unfortunately they are all group-reagents, and a group when once absorbed is not susceptible (practically) of further gasometric analysis. One or other of the absorbed components may be determinable otherwise—thus for instance H_2S (absorbed in KHO) by titration with iodine—but these are rare exceptions. For the analysis of a gas-mixture which, with regard to chemical absorbents, behaves as a whole, only two methods are at our disposal; one is to determine the ultimate composition of the gas (if possible), and from the results to try and arrive at the proximate composition; the other is to examine the gas by means of physical absorbents. But to obtain definite results with these we must follow the lead of Bunsen, and both contrive their application and interpret the results, in the light of the laws of gas-absorption.

Analysis by physical absorbents.

Imagine *v* volumes of a mixture of the unitary gases I., II., III., . . . to be shut up in a close vessel over h volumes of water or alcohol, an impervious diaphragm separating the two. As soon as the diaphragm is removed, the gas and liquid exchange molecules, and this goes on for ever; but if a constant temperature t is maintained, a point is reached, sooner or later, at which the changes of composition, exactly compensate each other, so that matters are the same as if the exchange had come to a stop. This point of dynamical equilibrium is reached almost instantaneously on violent shaking. The final result is that the gas-space v is saturated with the vapour of the liquid, while a quantity q of each of the components of the gas is held in solution by the h volumes of liquid. This quantity q *at a given temperature* is in (more or less exact) accordance with the equation—

---

[1] *I.e.* we may, if we choose, measure our *t*s with a Fahrenheit thermometer and take T as being $T = 459{\cdot}4 + t$ (in F. degrees).

[1] NO is absorbable also by the conjoint action of O and KHO solution, as KNO_2 and KNO_3.

$$q = h\beta\pi \quad . \quad . \quad . \quad . \quad . \quad (8)$$

where π means the partial pressure of the respective component in the residue, and β is a constant, which may be defined as being the value which q assumes when $h=1$ and $\pi = 1$ mm. q and β are, of course, of the same denomination; if q means mgms., β means mgms. likewise. But we will assume q to be measured by volume at 0° C. (or $T = 273°$ C.) and $P = 1$ mm., and on the basis of this assumption (with Bunsen) call β the 'co-efficient of absorption.'

Our equation has been tested experimentally only with water and, in a more limited sense, alcohol, as a solvent; and in reference to either, it may be assumed to hold, at pressures up to about 1 atm., and temperatures from 0° to about 30° C., for all gases which, under the circumstances, do not act chemically on, or dissolve very abundantly in, the respective liquid. With a given gas-species, β, in general, increases when the temperature falls, or when alcohol is substituted for water. It has, in general, different values for different species of gas. Hence we at once see our way towards distinguishing a unitary gas from a mixture. Take, for instance, the case of marsh-gas CH_4 as against a mixture of equal volumes of H_2 and $C_2H_6 = CH_4$ per 1 volume. With alcohol as an absorbent, the β of C_2H_6 is far greater than that for H_2. Hence, if the mixture be dissolved partially by alcohol, the residue will contain less carbon per unit volume than $\frac{1}{2}C_2$; and similarly in similar cases.

The relation between the composition of the mixture operated upon and that of the unabsorbed residue is easily formulated. Let m', m'', &c., stand for the quantities of the several components present in unit volume of the original gas, and let n', n'', &c., have a similar meaning in reference to the residue; let P stand for the (dry) pressure of the original gas, and p for that of the residue, then we have for any one of the components $q = h\beta(pn)$; and for the unabsorbed part of that component

$$r = (np)v\frac{273}{273+t} = (np)''v_0'',$$

and $q + r = pn(v_0 + \beta h)$; but $q + r = Pmv_0$, hence $Pmv_0 = pn(v_0 + \beta h)$, which enables us to calculate the 'n' of a named component from its 'm.' For further developments we refer to Dittmar's 'Exercises in Quantitative Analysis,' section on gas analysis (Glasgow, W. Hodge & Co.). Without mathematics it is clear that the quantity, λ, of total gas absorbed, reduced to $p=1$ and $h=1$, is

$$\lambda = \frac{v_0(P-p)}{hp}.$$

In the case of a unitary species λ is the *co-efficient of absorption*, and is consequently constant, while, in the case of a mixture it varies (in general) with $h:v$, *i.e.* with varying quantities of water for the same quantity of gas started with. Hence an obvious second method for testing a gas for chemical oneness.

Of general methods of gas analysis, only one remains to be considered. We refer to the

Method of Combustion.—A method of ultimate analysis which presumes that the gas to be analysed is in, or by addition of hydrogen or of oxygen or of either plus fulminating gas,[1] can be brought into, such a condition, that the mixture, when fired with an electric spark is resolved entirely into (in general) carbonic acid, nitrogen, and water, and excess of either hydrogen or oxygen as the case may be. The method consists in this that a measured volume of the given gas is exploded, and the gas quantities involved are measured as far as necessary to enable one to calculate the *elementary* composition of the gas under operation, the results being regarded customarily in volumes (reduced to some tacitly assumed constant disgregation) of the respective elementary substances. For uniformity's sake this system is extended even to the carbon, one volume of carbon being used as a phrase for the quantity of carbon contained in two volumes of carbonic anhydride. This mode of reporting comes to the same as stating the quantities of hydrogen, oxygen, &c., as multiples of the molecular weights H_2, O_2, N_2, and of the double atom C_2 of carbon. In the sequel we sometimes use H_2, O_2, N_2, CO_2, CO, as symbols for '1 volume.' When in a calculation we have to refer to a certain (reduced) volume of carbonic acid we designate it by the letter K; in a similar sense S refers to oxygen; W to water vapour; $\mathfrak{N}$ to nitrogen ('N' is reserved for the atom); O to contraction. The following examples explain the method:

I. The gas is a mixture of hydrogen and hydrocarbons; *i.e.* 1 vol. $= \alpha C_2, \beta H_2$. We determine the following gas-quantities:

(0) The volume of the sample, as . V
(1) " " plus added oxygen, as . . . V_1
And after firing
(2) The volume of the total product measured cold, as . . V_2
(3) The volume of the residue left after removal of the carbonic anhydride, as . . . . V_3

The quantity of carbonic anhydride produced in the combustion is 'K' $= V_2 - V_3$, whence $\alpha = \frac{1}{2}\frac{V_2 - V_3}{V}$.

The hydrogen is calculated from the '*contraction*,' meaning the difference 'O' $= V_1 - V_2$, thus: $V_1 = V + S$, where S stands for the added oxygen.

$V_2 = K +$ oxygen left unburnt, which is $S - K - x$, where x means the oxygen which converted the hydrogen into water. Hence $\mathrm{c} = \mathrm{v}_1 - \mathrm{v}_2 = \mathrm{v} + \mathrm{s} - [\mathrm{K} + (\mathrm{s} - \mathrm{K} - x)]$ or $\mathrm{c} = \mathrm{v} + x$; hence $x = \mathrm{c} - \mathrm{v}$, and $\beta = \frac{2(\mathrm{c} - \mathrm{v})}{\mathrm{v}}$.

---

[1] The mixture $H_2 + \frac{1}{2}O_2$ obtained in the electrolysis of water.

The sum $\alpha + \beta$ is, of course, always greater than unity unless $\alpha = 0$.

We will assume now

II. That the gas contains (in the v units taken for analysis) z volumes of free oxygen and y volumes of free nitrogen beside v_0 of hydrocarbons; both z and y being unknown. Here we at once see that the measurements of $\mathrm{v}_1, \mathrm{v}_2, \mathrm{v}_3$, do not enable us to calculate z or y. But we cannot even calculate the volume x of oxygen which combined with the hydrogen in the combustion; because from case I. we see that $x = \mathrm{c} - \mathrm{v}_0$, and v_0 is unknown. Nor does a direct determination of the oxygen-residue s_r in v_3 help us, because s_r is a function of c, independent of x and z. We have, in fact:—

$$\mathrm{s}_r = z + \mathrm{s} - x - \mathrm{K};$$
$$\mathrm{c} = \mathrm{v} - (z + y) + x;$$

$$\mathrm{s}_r + \mathrm{c} = \mathrm{s} - \mathrm{K} + \mathrm{v} - y;$$

and
$$\mathrm{s}_r = -\mathrm{c} + \mathrm{s} - \mathrm{K} + \mathrm{v} - y.$$

The determination could only confirm this calculation. If z is known to be $= 0$, or z and y conjointly are known to be so much *air*, the problem becomes easy of solution.

III. The gas is $\alpha C_2.\beta H_2.\gamma O_2.\delta N_2 = 1$ volume; states of combination unknown. If we add to the values (for v of substance) of K and c that of the nitrogen in the ultimate residue (let its quantity be $= \mathfrak{N}$) we have α and δ at once. But, (even supposing we did not care for γ), to determine β we must measure the quantity, w, of steam produced in the combustion. From w we have $\beta = \frac{1}{\mathrm{v}}\mathrm{w}$; and from this, and the contraction c, we can calculate γ thus; let s_0 denote the quantity of oxygen which, conjointly with the oxygen in the substance, is just sufficient to burn the substance into CO_2, H_2O, and N_2, and let s_r be the surplus added, so that $\mathrm{s}_r + \mathrm{s}_0 = \mathrm{s}$; we have

$$\mathrm{v}_1 = \mathrm{v} + \mathrm{s}_0 + \mathrm{s}_r$$
$$\mathrm{v}_2 = \mathfrak{N} + \mathrm{K} + \mathrm{s}_r$$

$$\mathrm{c} = \mathrm{v} + \mathrm{s}_0 - \mathfrak{N} - \mathrm{K};$$

or,
$$\mathrm{v}_1 - \mathrm{v}_3 = \mathrm{v} + \mathrm{s}_0 - \mathfrak{N}.$$

Now, it was obviously the oxygen sum $\mathrm{s}_0 + \mathrm{v}\gamma$ which produced the H_2O and CO_2; hence,

$$\mathrm{s}_0 + \mathrm{v}\gamma = \mathrm{K} + \tfrac{1}{2}\mathrm{w};$$
$$\therefore \qquad \gamma = \frac{1}{\mathrm{v}}(\mathrm{K} + \tfrac{1}{2}\mathrm{w} - \mathrm{s}_0).$$

Whenever, in a gas of unknown constitution, oxygen *may* be present, the determination of w becomes indispensable, because without it the water possibly present in a gas would escape us altogether; we could not, for instance, discriminate between ethylene and oxide of methyl.

The case which we have just been discussing includes that of the analysis of any gas $\gamma O_2.\delta N_2$ which is combustible by means of hydrogen. Because the added hydrogen, for calculating purposes, may be included in the 'v' of our formulæ, to be ultimately allowed for. In practice, however, the variety of proximate compositions included in the formula $\gamma O_2.\delta N_2$ is very small, so that, in the case of such a gas, we had better at once calculate the proximate components (N_2, N_2O, O_2 &c.) directly from the data of the combustion.

IV. Let us now see how far the method of combustion goes as an *indirect* method of proximate analysis. Let us assume that we have to deal with a gas of the nature pre-supposed in case III., and that the quantities, K, c, w, $\mathfrak{N}$, have been determined, and none of them found $= 0$. We also assume that we know the formulæ of all the several species I., II., ..., which can possibly be present. To find the quantities of these contained in unit-quantity of the given gas (x' for I.; x'' for II. .....) we might begin by calculating the *elementary* composition of our gas, *i.e.* the coefficients in the average formula $\alpha C_2.\beta H_2.\gamma O_2.\delta N_2 = 1$ vol., and then express these algebraically in terms of the special values α', α'' ......, β', β''......, &c., appertaining to the components I., II......., &c., thus,

$$\alpha = \alpha' x' + \alpha'' x'' + \alpha''' x''', \text{ \&c.} \quad . \quad . \quad \text{I.}$$
$$\beta = \beta' x' + \beta'' x'' + \beta''' x''', \text{ \&c.} \quad . \quad . \quad \text{II.}$$
$$\gamma = \gamma' x' + \gamma'' x'' + \gamma''' x''', \text{ \&c.} \quad . \quad . \quad \text{III.}$$
$$\delta = \delta' x' + \delta'' x'' + \delta''' x''', \text{ \&c.} \quad . \quad . \quad \text{IV.}$$
$$1 = x' + x'' + x''', \text{ \&c.} \quad . \quad . \quad . \quad \text{V.}$$

In practice, of course, we need not calculate α, β, &c., but may at once form equations between $\frac{1}{\mathrm{v}}\mathrm{K} = k$; $\frac{1}{\mathrm{v}}\mathrm{c} = c$; $\frac{1}{\mathrm{v}}\mathfrak{N} = n$, &c., and the special values $k'k''$..., $c'c''$..., $n'n''$..., thus—

$$k = k'x' + k''x'', \text{ \&c.} \quad . \quad . \quad . \quad \text{I.}a.$$
$$c = c'x' + c''x'', \text{ \&c.} \quad . \quad . \quad . \quad \text{II.}a.$$
$$w = w'x' + w''x'', \text{ \&c.} \quad . \quad . \quad . \quad \text{III.}a.$$
$$n = n'x' + n''x'', \text{ \&c.} \quad . \quad . \quad . \quad \text{IV.}a.$$
$$1 = x' + x'', \text{ \&c.} \quad . \quad . \quad . \quad \text{V.}a.$$

and solve *these* equations; but the former set shows more clearly how far the method goes as a method of proximate analysis.

From either set we at once see that if the number of potential components does not exceed *five*, we can in general calculate the quantity of each in unit quantity of gas, *i.e.* $x'\,x''\ldots x^{\text{v}}$. *In general* we say, because obviously if one or more of the co-efficients α, β...is $= 0$, so many equations collapse; in the case, for instance, of $\gamma = 0$ and $\delta = 0$, only three equations are left. And (to adhere to the example) if it should happen that all the values of β are the same function of the respective values α, then equation II., or, if you prefer it, equation I., is lost, and only the case of two components is susceptible of a solution. A similar result occurs if all the components should happen to contain the same number of hydrogen-atoms (or the same number of carbon-atoms) per molecule. Supposing, for instance, all the components were of the general formula C_xH_6 then β would by necessity be $= 3$, and equation II. would be resolved into $3 = 3x' + 3x'' + 3x'''$... which is a mere repetition of equation V. And similarly, if all the components were di-carbon gases, equation I. would become useless.

The general rule is, first of all to find out how many of the quantities k, c, n, w... *in addition to our knowledge of the constitution of the gas*, we should need to calculate the co-efficients α, β... of the average formula. Supposing 4, 3, 2 suffice, then (in general) 3, 2, 1, (but not *any* 3, 2, 1), equations of the second set, taken along with equation V..., will suffice to find the unknown quantities x', x''... sought, provided their number does not exceed 4, 3, 2.

For examples see the writer's *Tables to facilitate chemical calculations* (Williams & Norgate).

The following table gives the values of c, k, s_0, w for several gases.

I.—*Combustible by Oxygen.*

The Practice of Gas Analysis.

In this section we take cognisance only of the chemical methods, and in regard to these confine ourselves in the main to those apparatuses in which mercury serves as a trapping fluid.

Taking ordinary laboratory appliances for granted, all that gas analysis demands of special apparatus is: a barometer, a pneumatic trough with transparent sides, and a series of glass tubes, closed at one end and open at the other, and provided, virtually, with two scales, of which one divides the gas capacity, and the other the axis, into units of sufficient smallness. One or more of these tubes must be provided near the closed end with a couple of fused-in platinum wires so that a combustible gas-mixture in it may be exploded by means of an electric spark. The possibility of obtaining exact results by means of these simple contrivances is proved by the fact that all the great gasometric work of Cavendish and Gay-Lussac, which laid the foundations for our present chemistry, was done with apparatus like those referred to, or even with apparatus of a lower order of complexity. Of course to obtain exact results we must be alive to all the numerous sources of error involved, and eliminate them as far as possible experimentally or otherwise. It is one of the merits of Bunsen to have done this for us, and to have thus brought the old method of gas analysis into a form which, on the score of precision at least, leaves nothing to be desired.

Bunsen's Apparatus and Methods. The first requisite of exact gas analysis, Bunsen says, is a special room in which the temperature is subject to only slight, and to no sudden, variations. The ideal gas-room forms part of a substantial building; it is not warmed artificially nor is it contiguous to any other room thus heated; and its windows face the North, to keep out the sun. In such a room the temperature during a working-day remains constant as a rule to within 1°C. although the variations of temperature of the outside air may amount to as much as 12°C. A characteristic of Bunsen's method is that the chemical treatment of a gas is effected in the tube in which it has been measured; but he uses two kinds of tubes, one for the absorptions, the other (eudiometers) for the combustions. Both are about 20 mm. wide (inside measurement; in narrower tubes the capillarity assumes measurable values) and 2 mm. or so strong in the body, which strength suffices even for the eudiometers. The absorption tubes are about 250 mm. long, and are provided with spouts, so that a gas contained in one can be transferred to another tube by laying down the absorption tube in the trough. In the case of the eudiometers a length of 500–600 mm. suffices for all ordinary purposes. The platinum wires are fused in somewhere near the closed end, and are bent so that the two ends stand opposite each other at a distance of about 2 mm. Every gas tube is provided with an etched-in millimetre-scale, and the gas-volumes corresponding to the several marks are determined by calibration, so that each tube is a laboratory, a volumeter, and a manometer, in one. The scale is figured from the closed end downwards. To calibrate a tube it is fixed, open end upwards, in a vertical position; successive, exactly equal, quantities of mercury are introduced, each corresponding to some 20 mm. of scale, and after each such addition the exact position of the top of the meniscus in reference to the scale is observed by means of a horizontal telescope standing at a distance of 1–2 metres, and the readings are taken down, care being taken, before each reading, to remove any air-bells that may be imprisoned between the mercury and the sides of the tube, by means of a long stick of whalebone. The measuring off of the standard volume of mercury is effected by means of a short stout test-tube, ground exactly flat at its lipless rim, and provided with a lid of ground plate-glass. It is filled from a pipette-like reservoir provided with a long narrow outlet tube and a stop-cock at the top end of this tube. If care be taken so to operate that the mercury, while it fills the measure, forms one continuous mass, the formation of air-bells is easily avoided. The measure, while being filled, is held in a wooden clip (not directly in the hand, which would cause the mercury to expand) while the lid is slung to the thumb of the same hand. The measure is filled to overflowing, the excess of mercury is removed by putting on the lid, and the mercury is poured into the tube.

The mercury-measure is assumed to hold

---

* h = hydrogen necessary for combustion.

† Nitric oxide cannot be burned with H_2 alone; it requires addition of a certain proportion of N_2O; and even then the combustion is irregular (Bunsen, *Gas. Meth.* 2nd Ed. pp. 95, 96).

'*v*' volumes of mercury, v being so chosen that, for differences of capacity at least, the numerical value of the volume corresponds as nearly as possible with the respective scale readings, so that, for small differences, every 1 mm. of difference of level can be assumed to correspond to unit-volume (*i.e.* to $\Delta \mathrm{v}=1$). Supposing after addition of k measures full of mercury the meniscus stands at R mm., the volume of the body of quicksilver now in the tube is kv units by definition; but the gas-volume corresponding to R is greater than kv, by the volume x of the |⋈|-shaped space between the meniscus as it is when the gas is being measured, and the meniscus as it was in the calibration. To determine x, we pour some corrosive sublimate solution on the meniscus (after having read off the number R in calibration) which causes the meniscus to flatten out into a plane, and we read the position of this plane which stands say at R–δ mm. Counting from some horizontal reference-plane 00 upwards, the volume of the mercury and the total space from 00 to the horizontal plane through R are constant. The volume $\frac{1}{2}x$ has become visible as a cylinder of the height δ millimetres, and consequently of the capacity of δ 'units.' Hence the gas volume corresponding to point R is $kv+2\delta$. From the values $kv+2\delta$, and the corresponding readings R′ R″ R‴ &c., it is easy (though tedious) to calculate a calibration table which gives all the gas-volumes from mm. to mm. directly. In reading off with a good telescope one soon learns to divide every individual degree into tenths by the eye; the (Δv)s corresponding to them are found by interpolation from the tabular entries. Should the tube be used for measuring over water, we remove the meniscus-correction by subtracting 2δ from the registered volume, and thus obtain as good an approximation to the gas-volume over water as is called for in such a case.

During the course of the calibration the temperature of the mercury must be kept as nearly as possible constant, or else the values recorded for the lower marks may be very appreciably incorrect. It is well to record the mean temperature t_0 during the period of calibration, and to determine the weight in grams of a measure-full (v 'volumes') of mercury at $t°$, in order to be prepared for reductions of gas-volume to gas-weight. One gram of mercury at 0°C. occupies 0·07355 c.c. (log. $\bar{2}$·866589), and the volume at t°C. is $0{\cdot}07355\ (1+0{\cdot}0001814\ t)$ c.c.

To prepare a eudiometer for receiving a gas we first make it rigorously clean, and next, if the gas is meant to be measured 'moist,' attach a small drop of water to the closed end, which during the operation of filling with mercury gets flattened out and spread over the inside, and so offers a large surface to the gas. The mercury is introduced through a long funnel-tube (provided with a stop-cock at the bottom of the funnel) which goes to the bottom of the eudiometer. By means of this arrangement it is easy, after the introduction of the first thimble-full of metal, to let the mercury in eudiometer and funnel form one unbroken mass, and thus to avoid formation of air-bells at the sides of the tube.[1]

Assuming the gas to have been introduced, and the tube to have been fixed in a vertical position, we begin by preparing for the reading of the level of the trough by inserting a paper screen, provided with a ⬭ shaped perforation, between the mercury and the front (glass) wall of the trough, which gives a fairly distinct image of the line of intersection between scale and trough-level plane; we then suspend the thermometer somewhere close to the tube and next leave the room for a time to allow the gas to assume the temperature of the air. On returning we read off:

1. The position R of the meniscus in the tube.
2. The level of the mercury in the trough, R_0.
3. The temperature, $t°$.
4. The barometer; let its height be $=$ B mm.

This reading comes last because the barometer requires to be tapped before being read and this cannot be done from a distance.

In the vast majority of cases the temperatures $t't''t'''$... for the several gases to be compared do not differ much from their mean; hence, even if they differ considerably from the temperature which prevailed in the calibration, the value furnished by the calibration table for R can be put down as the correct relative volume of the gas measured; and the pressure of any mercury-column measured may be identified with its nominal height in mms. as read. Hence we have for the pressure of the dry gas at the observed volume $\mathrm{P}= \mathrm{B}+\mathrm{R}-(\mathrm{R}_0+\pi)$ where π is the maximum pressure of steam at $t°$, and for the gas-quantity (the volume reduced to unit disgregation) $v_0=\dfrac{v\,\mathrm{P}}{273+t}$ (see theoretical part).

Bunsen prefers reducing to 0°C. and 1000 mm. pressure by the formula

$$v_0=\frac{v\,\mathrm{P}}{1000(1+0{\cdot}003665t)}$$

which, if a table of the logarithms of all the values $(1+\alpha\,t)$ is at hand, is as short a method as the one recommended by us.

Corrections of tube-capacities and mercury-heights for variations of temperature occur only in the rare case when one of the gases concerned in the analysis was measured at an artificially established high temperature t. In this case the value v furnished by the calibration table for the reading R must be corrected thus:—

$$(\text{True capacity down to R}) = \mathrm{v}[1+\lambda(t-t_0)]$$

where λ stands for the coefficient of the cubical expansion of glass, and may be put down at $27{\cdot}6\times10^{-6}$. And for the observed height h of a mercury column measured at a high temperature t we must substitute the height h_0 of the equivalent column of mercury of t_0 degrees. t_0 stands in both cases for the average temperature that prevailed during the determinations made in the ordinary manner. Obviously $h_0=\dfrac{h(1+k\,t_0)}{1+k\,t}$ and with sufficient exactitude.

$$h_0=h\,[1-k\,(t-t_0)]$$

---

[1] In regard to the collection and preservation of gas samples, and the mode of introducing a sample into the eudiometer, we refer to Bunsen's *Gasometrische Methoden*, second edition, Braunschweig, 1877. The first edition, 1857, was translated into English by Roscoe, and published by Walton and Maberley, London.

$k = \cdot 00018$.—Strictly speaking the nominal value L of a piece of millimetre-scale as measured at t should be corrected thus:

$$(\text{True length at } t) = L(1 + (t - t_0)9{\cdot}2 \times 10^{-6}).$$

(It is easier to remember that 1000 mm. expand by 0·92 mm. per 100° of increase of temperature.) But our work must be very exact to be worth this correction. It is more relevant to state that whenever we wish to make use of Regnault's determinations of absolute gas-densities we must measure by his unit of (temperature and) pressure, and consequently reduce our mercury-columns to true mm. of mercury of 0°C. Regnault's densities D, on the other hand, ought to be reduced to the gravity of the place of observation; this correction, however, may as a rule be neglected.

For the execution of an *absorption* the most obvious method is to shake the gas with the respective reagent in the liquid form, and to measure the gas-residue as it stands over the layer of liquid reagent. But this method is in general attended with a number of obvious grave errors, and, besides, does not readily adapt itself to the successive application of different reagents. To overcome these difficulties Bunsen, as a general rule, uses all the absorbents in the form of solid or semi-solid balls, fixed each to the end of a platinum wire. Caustic potash, chloride of calcium, &c., are cast in a bullet-mould around the coiled-up end of the wire. To bring sulphuric acid, alkaline pyrogallate-solution, and other intrinsically liquid reagents into a *quasi*-solid form, a ball of some suitable porous material—battery charcoal for vitriol; papier-maché for pyrogallate, &c.—is fixed to the end of the wire and the ball is then soaked in the respective liquid. In this manner it is quite possible to accomplish an absorption even with oil of vitriol, without soiling the tube or the mercury to an inconvenient degree. Reagent vapours left after an absorption, or foreign vapours produced by the reagent—*e.g.* the SO_3 and SO_2 which are always left after an absorption of olefines by fuming vitriol—must of course be removed by suitable reagents (SO_3 and SO_2 by a soft potash ball) before the residue is measured. As small remnants of, for instance, KHO, remain unavoidably in the tube, the residues must in general be measured dry, because the pressure of water in the presence of moist KHO is incalculable.

The weak point in Bunsen's method is that it is tedious, and that it does not enable one to see the end of an absorption otherwise than by the repetition of the process with a fresh reagent ball. Bunsen himself has indeed come to effect carbonic acid absorption, by shaking the gas with solution of caustic soda, and measuring the gas-residue over the layer of reagent. To be able to correct for the pressure of this layer and for the vapour-pressure of the reagent, he employs it in the form of a standardised solution containing exactly 7 p.c. of NaOH, which has a practically constant specific gravity. He has also determined the course of the pressure-curve by standard experiments; the results are embodied in a table appended to his *Gasometrische Methoden*, second edition.

In this connection we must refer to an ingenious method devised by Russell (*C. J.* [2] 6). He introduces the reagents as solutions by means of a graduated syringe; and after they have done their work, removes them by means of a ball of cotton-wool, previously rendered air-free by kneading it under mercury. To remove what adheres to the tube and mercury he rinses the inside with some injected water and removes this by a fresh cotton-wool plug.

In the analysis of a gas by combustion a necessary preliminary step is to remove (and determine) what there may be of SO_2, CO_2, NH_3, and similar gases, by suitable absorbents. Part of the residue is transferred to the eudiometer and measured. Let its volume (reduced to, say, unit disgregation) be equal to v units. The necessary quantity of oxygen or hydrogen is now added and its quantity is determined by measuring the mixture (let its red. volume be v'). The mixture is now rendered explosive, if necessary, by adding the requisite proportion of fulminating gas, the whole is well mixed and prepared for explosion by pressing the open end of the eudiometer firmly against an india-rubber pad lying on the bottom of the trough. The upper surface of the pad must have been rendered air-free by rubbing it over with a few drops of corrosive sublimate and mercury. After these preliminaries the combustion is effected by passing an electric spark through the mixture. After the combustion, the eudiometer is carefully lifted from its cushion, so that the mercury enters slowly and without drawing in air. The gas, after having been allowed to cool down to the temperature of the room, is measured, to determine its reduced volume v''. From the data obtained so far, we have for the contraction per unit of original gas;

$$c = \frac{1}{v}\,(v' - v'').$$

After this determination comes, if necessary, that of the water produced, which of course is practicable only if the original gas and the added oxygen were used in the state of perfect dryness and any added fulminating gas measured exactly. To determine the water—of which part in general separates out in the liquid form—the eudiometer is lifted out of the trough by means of a small beaker, and with it, as its temporary trough, placed within a glass cylinder through which a current of steam can be passed to raise the temperature of the whole to something like 100°C. The exact temperature t''' is noted down. If care be taken to arrange matters so that the pressure of the gas mixture produced is not more than 0·5–0·6 atmospheres the steam may be practically regarded as a perfect gas, so that the measurement of the mixture enables one to calculate its quantity. If the red. volume of the mixture be v''', we have for the steam per unit of original gas;

$$w = \frac{1}{v}\,(v''' - v'').$$

In this measurement the corrections for the expansion of the glass and mercury, which were referred to above, necessarily come in.

The determination of the carbonic anhydride produced is effected by caustic potash. In an aliquot part of the residue, the surplus-oxygen (or hydrogen if we have to deal with a gas combustible by hydrogen) is determined, if necessary. Oxygen can be determined by explosion with excess of hydrogen (its quantity is ⅓ of the contraction), or it may be determined by absorption with pyrogallate; hydrogen is determined by explosion with excess of oxygen, ⅔ of the contraction is the volume of the hydrogen. The nitrogen is found by difference. The method of combustion—as a method of ultimate analysis at least—is susceptible of a high degree of precision, which, however, is attained only if we take care to avoid its numerous sources of error.

I. The reagents used must be absolutely pure, which of course includes absence of air; hence in any case the gas-evolution apparatus employed should be no larger than is absolutely necessary, so that the air-space is reduced to its minimum.

Pure *oxygen* is easily made. A few grams of pure potassium chlorate are introduced into a little bulb blown to the end of a glass tube, and the latter is then drawn out and bent into the form of a gas-delivery tube. The rest needs no explanation.

Pure *fulminating gas* is best produced electrolytically from 10 per cent. pure sulphuric acid. The two elements are sure to be produced in the exact ratio of $H_2:\frac{1}{2}O_2$, but whether the gas as it comes off really has this composition depends on the observance of certain conditions which cannot be formulated better than by a description of Bunsen's apparatus (Fig. 1).

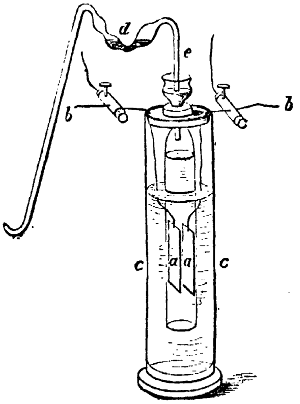

FIG. 1.

The decomposition-cell consists of a cylindrical bottle provided with fused-in platinum electrodes *aa*, and terminating in a funnel; it is filled with the acid up to about ⅘ths of its capacity. The end *e* of the washing-bulbs and delivery-tube is ground into the neck of the funnel; a few drops of acid poured over the joint make it absolutely tight. The bulbs *d* are charged with a few drops of oil of vitriol to dry the gas evolved. The bottle is suspended within a bath of water *c c* (or alcohol to avoid its freezing in winter-time). To produce a current of fulminating gas, the wire ends *bb* are connected with the poles of a battery of four 'Grove' or 'Bunsen' cells, and the gas evolved during the first five minutes is allowed to escape in order to expel the air, and to establish absorptiometric equilibrium between the gas above, and the gas held in solution by, the acid. As oxygen has a greater coefficient of absorption (β') than hydrogen (β''), the first portions of gas that come off contain an excess of hydrogen. Besides, the ratio $\beta':\beta''$ varies with the temperature; for this reason, and also to avoid undue heating of the conducting-wires, the bath is used.

Imagine the apparatus to be so modified that the oxygen electrode is immersed in a mass of liquid zinc-amalgam, which takes up the oxygen as quickly as it is liberated from water, and you have Bunsen's apparatus for producing pure *hydrogen*. But a sufficiently pure gas for most purposes can be obtained in the ordinary manner, namely, by the action of 10 p.c. (pure) sulphuric acid on pure zinc, in the presence of platinum, within a small, narrow-necked, flask. The hydrogen thus evolved is filtered through a short narrow tube full of fragments of caustic potash to remove traces of sulphuretted hydrogen and moisture.

II. The second point to be attended to is that the quantity of oxygen (or hydrogen) added to the gas to be burnt must be in excess over the calculated quantity (a *large* excess is not necessary). The mixture must be perfectly homogeneous before the spark is sent through it.

III. The gaseous mixture must be brought to a proper state of attenuation. Let us assume that the gas to be burnt is a pure specimen of H, CO, CH_4, or some other gas, C_xH_y. A glance at the formula shows how many volumes of oxygen we have to add to produce what we may call the respective fulminating gas. Thus the equation $C_2H_4 + 3O_2 = 2CO_2 + 2H_2O$, tells us that every one vol. of ethylene needs 3 vols. of oxygen. Any fulminating gas will explode when the spark is sent through it at the ordinary pressure, but the force of the explosion is in general more than the best eudiometer will stand. To avoid such accidents, we must attenuate the gas by addition of diluents (such as surplus oxygen or air), or by mere expansion, or in both ways. In practice we must go even beyond the safety point, because in most cases nitrogen is present even in the original gas, and a considerable quantity of this nitrogen may be converted into nitric acid if the temperature of the flame is too high. But we must take care on the other hand not to attenuate too largely, or else the mixture may miss fire, or, what is worse, suffer only partial combustion. The effect of an explosion—in the chemical, physical, and mechanical, sense—is determined by many independent variables, which, if arranged in the order of their importance, would begin with the chemical constitution of the gas to be burnt, and end with the relative narrowness of the eudiometer. But given a certain eudiometer, and suppose it to be charged with a certain fulminating gas which contains, let us say, unit vol. of the respective '*fuel*,' measured at the ordinary temperature and the pressure of one atmosphere, the attenuation of this gas to a certain eudiometer space, equal to Λ units of vol., will render the explosion both safe and effective. Λ of course has one value if the attenuation be produced by mere expansion (mere reduction of pressure), another value if it be produced—at, say, 1 atm. pressure—by addition of air, a third, fourth, &c., in intermediate cases; each case fortunately admits of a liberal toleration, $\pm(\Delta A)$. The A for a given species of fuel can of course be determined only by experience; supposing it has been ascertained for H, CO, CH_4, and the value for CH_4 is A_0, we might suppose that the proper A for C_2H_4 or C_2H_6 would be about $2A_0$, that for a C_3-gas about $3A_0$, &c.; but unfortunately the supposition is not borne out by experience; C_2H_2, for instance, explodes far more violently than C_2H_4, although it contains less hydrogen per molecule. But to pass to experience. According to Bunsen and Kolbe, the explosion of ordinary fulminating gas ($H_2 + \frac{1}{2}O_2$) in admixture with air takes its normal course at from 500 to 600 mm. total pressure, if the percentage of the explosive gas lies between 20·8 and 39·1. According to our calculation from the data of the five experiments recorded by Bunsen, this comes to the same as saying, if the partial pressure of the fulminating gas lies between 108 and 230 mm.; or if A, referred to the hydrogen, is between 4·9 and 10·5. If $A > 10{\cdot}5$, the gas fails to burn; if $A < 4{\cdot}9$, nitric acid is produced. In the combustion of a given quantity of oxygen by added hydrogen, we may use 3–10 volumes of the latter, per 1 vol. of oxygen, if we start with almost pure oxygen. In the analysis of ordinary air, 0·5 – 1 vol. of hydrogen per 1 vol. of air works well (Bunsen). Whenever hydrogen is used as a reagent, the chance of nitrogen being drawn into the combustion is relatively small, so that we have greater latitude on this score, in choosing our conditions. If the oxygen to be determined is accompanied by an unknown proportion of nitrogen, we first try two volumes of hydrogen for one of total gas; if the mixture fails to explode properly we add the requisite proportion of fulminating gas, *i.e.* so much of the latter that it forms about 40 p.c., but no more, of the whole, and explode again; this time presumably with success (Bunsen). In the case of marsh gas, Bunsen directs us to add 8–12 volumes of air besides the necessary 2 volumes of oxygen, which, assuming the mixture before the explosion to be at 600 mm., makes our A equal to 14 to 19. For C_2H_4, his directions are somewhat obscure, but in a test-analysis quoted by him, the pressure of the mixture as exploded was 546 mms., and it contained 0·04868 of its vol. of C_2H_4. Hence $A = 28{\cdot}6$; and the partial pressure of the explosive gas ($C_2H_4 + 3O_2$) was 106 mm.

The addition of large volumes of air to the gas to be analysed does not of course add to the precision of the work generally, and in the best case will render the determination of the nitrogen in the ultimate product somewhat uncertain.

Thomas (*C. J.* 35, 213) was the first to substitute mere expansion for dilution; the (Frankland) apparatus he used enabled him to do this without trouble. Lothar Meyer and Seubert (*C. J.* 45, 581) have lately taken up the same method and rendered it available for Bunsen's apparatus by the invention of an auxiliary apparatus in which a kind of mercurial air-pump, constructed on the Geissler principle, serves to establish any desired pressure at the same time in the eudiometer and in a moist-vacuum barometer, so that the difference of level between the meniscuses of the two at once gives the pressure of the dry gas. By means of this apparatus, they ascertained, for each of a series of gases combustible by oxygen, the minimum pressure at which the undiluted fulminating gas is exploded by an electric spark, and also a range of pressures at which the explosion is both safe and effectual. The following table summarises what for us are the main results. To explain the headings let us give the reading of the table for CH_4 in full. Imagine a given quantity of marsh gas mixed with a little more than two volumes of oxygen; this mixture will explode normally if its pressure is reduced to $P = 140$ mm. by mere diminution of pressure, the partial pressure of the CH_4 itself will now be at 47 mm., and its attenuation (as defined above) at $A = 16$, that is to say, every 16 units of vol. of the expanded mixture contains 1 vol. of CH_4 measured at 760 mm.

Fuel	P	p	A
	in millimetres		
CH_4	140	47	16
C_2H_4	70–80, say 75	19	40·5
C_2H_2	40–50, say 45	13	59·1
C_3H_6	80	14·5	52·2
C_3H_8	80	13·3	57·0
CO	243–219	162–146	4·7–5·2
H_2	176–127	117–85	6·5–9
	(*Partial Pressures.*)		
[H_2	176–127	117–85	4·9–10·5]

[By Bunsen and Kolbe's experiments (*vide supra*); air added as diluent; *total* pressure in the mixture as exploded, 520–590 mms.]

With Meyer and Seubert's, or some other equivalent, apparatus at hand, the order of operations with a gas of unknown composition is as follows:—After having added a sufficient volume of oxygen, we next expand so largely as to be certainly on the right side of the safety line, and apply the spark; if no explosion occurs we repeat the trial at successively greater pressures. Should the greatest available pressure fail to produce inflammability, we add a suitable proportion of ordinary fulminating gas ($H_2 + \frac{1}{2}O_2$) as above explained, &c., &c.

The Bunsenian mode of gas-analysis, while perfection in regard to precision and elegance, is very wasteful of time, for obvious reasons, which any reader who has followed us so far will easily discern. The desire to do away with this evil has led to the construction of quite a series of more or less complicated gas apparatus. The more important of these are described in the following paragraphs. To avoid repetitions, let us state beforehand that all the apparatus to be noticed agree in the following points:—

1. For accelerating the absorptions the reagents are all used as liquids, and the absorptions are carried out in a special piece of apparatus (*laboratoire*); the residual gas is then transferred to the *measurer*, where it is saturated with vapour of water, and measured.

2. The measurer is immersed in a water-bath to bring the gas contained in it to a definite constant temperature, without much loss of time.

3. The mode of measurement is so contrived that the calculation of the gas-quantities (the QS) becomes very easy or even unnecessary.

Regnault and Reiset (*A. Ch.* [3] 26, 333), while engaged in their great research on respiration, felt the want of a quick-working apparatus for the numerous gas-analyses involved, and at last adopted the combination represented in figs. 2 and 2*a*. The vertical tube A conjointly with the moveable trough V constitutes the *laboratory*; the measurer consists of a long U-tube, the limbs of which are of glass, while the bend consists of an iron or steel tube, terminating in two sockets *b* and *c* (see auxiliary figure 3), in which the two glass tubes B and C are fixed by means of a resinous cement. A two-way cock R below B (fig. 3) enables one to effect the necessary connections. Tube B is provided with a couple of fused-in platinum wires near its top, so that it can be used for the combustions as well as for the measurements of the gases. Tube C conjointly with B serves as an open manometer. The capillary ends of A and B are cemented, each into the socket of a capillary steel stop-cock, and the ends of the two steel-fittings which face each other are shaped so as to constitute the two halves of a *Regnault*-*coupling*, so that the two tubes can be united hermetically, or can be separated, at a moment's notice. The construction of a Regnault's coupling is seen from fig. 4. To unite A and B, the convex end of *r* (fig. 4) is smeared over with melted india-rubber, pressed against the concave part *a′ b′*, and the two are then bound together by means of the clip *a″*. As the conical groove in *a″* has a slightly less angul aperture than the sharp welt which it go over, if the two halves of *a″* are screwed again each other, they exert a powerful pressure, an make the joint absolutely tight. The volumete B, in the original apparatus, had only o mark, somewhere about the middle; but th inventors subsequently added two more, on close to the upper end, and one near the lowe for the measurement of exceptionally small, o large, quantities of gas. The manometer C i not graduated, as the apparatus is intended t be used with a cathetometer; where this costl instrument is not at hand, tube C must be pro vided with a millimetre scale.

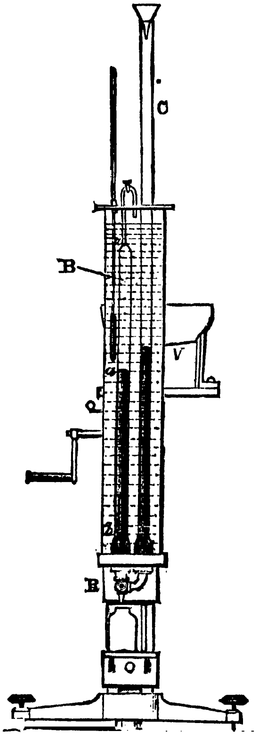

FIG. 2.

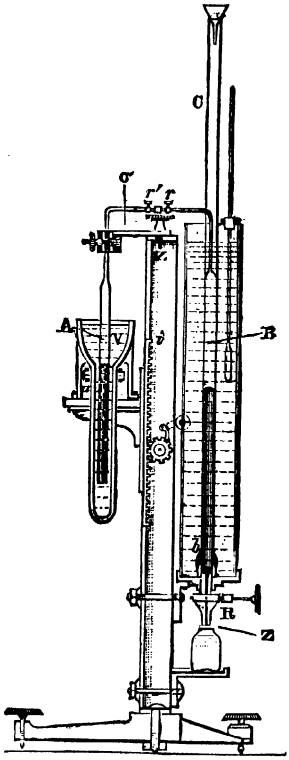

FIG. 2*a*.

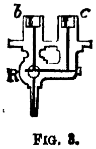

FIG. 3.

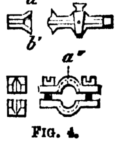

FIG. 4.

To prepare the apparatus for use it is place on a substantial support not liable to incon venient vibration, and the three levelling screw of the stand are adjusted so that the tube B and C stand vertical. To determine th relative gas-volumes corresponding to the thre marks, the volumeter is filled with mercury, through C, and after the air-bells have been removed by the well-known artifices, the weights of mercury w_1, w_0, w_2, which the tube holds from its exit-end at *r* (fig. 2*a*) to the highest, middle, and lower, mark, respectively, are determined. For comparative measurements the volumes are put down as $\frac{w_1}{w_0}$, $\frac{w_0}{w_0}=1$, and $\frac{w_2}{w_0}$, respectively. In the absence of a cathetometer the level points of the three marks on the scale C must be determined with the help of an ordinary gas-room telescope. Lastly, a drop of water is introduced into B and spread over its surface. To analyse, say, a mixture of carbon dioxide, oxygen, and nitrogen, a sample of the gas is collected over mercury in A (perhaps with the help of an auxiliary-trough); tube A is coupled on to B (which is supposed to be quite full of mercury), and the gas is sucked into this tube by letting mercury run out at Z. B having been closed by shutting the cock *r*, communication is made with C, and mercury is run out until the meniscus in B stands at say exactly the middle mark; the final adjustment is made with the telescope when the temperature of the gas has certainly become equal to that of the bath. When the final reading is made, B must of course communicate with C only. The reading of the height *h* of the mercury column in C, counting from the respective mark up or down as the case may be, and the reading of the barometer, complete the measurements. Supposing *h* to be positive, and the barometer to stand at B, the gas-quantity measured is

$$Q=\frac{(V_0=1)\times(h+B-\pi).}{273+t}\ .$$

To absorb the carbon dioxide, the laboratory tube (which was left full of mercury) is charged with a little caustic potash solution, and the gas is blown into it from B. By letting the gas travel forwards and backwards between A and B a number of times, the absorption can be completed in a short time. The residual gas is then sucked back into B, care being taken to shut the cock *r′* as soon as the potash solution comes to some mark σ, in the capillary part of A. The thread of gas from σ to *r* which is thus lost is of no consequence, as it amounts to only $\frac{1}{3000}$ of V_0. The mixture of nitrogen and oxygen is measured as before. The rest requires no explanation. If all the several gases are measured at the same temperature and volume, the (dry) pressure P', P'', P''', of course may be taken as representing their Qs (red. vols.).

Frankland and Ward, in 1853, introduced an ingenious modification of Regnault's apparatus, which differs from the original model chiefly in this, that the volumeter bears ten marks, so adjusted that the respective gas-volumes are to one another as 1 : 2 : 3 . . . . 10 exactly, and that in addition to Regnault's open tube C (Figs. 2, 2*a*), there is a third tube, D, which terminates above in a stoppered funnel or stop-cock. Tube D stands in the same water-bath with B and C; when used it contains only mercury and a little water, and thus assumes the character of a 'moist' barometer, which serves to directly measure the *dry* pressure of the gas shut up in B. Tube C (in F. and W.'s apparatus) serves only for the introduction of the mercury. The levels of the ten volumeter marks, in reference to the scale on the barometer, are of course determined once for all, hence the measurement of a gas, supposing its volume to have been adjusted to one of the ten marks on the volumeter, involves only one reading, namely that of the height of the mercury column in the barometer, which balances the (dry) pressure of the gas. Another advantage of F. and W.'s apparatus is, that for each gas measurement it gives one the choice among at least some three of the ten standard volumes, and thus enables one to reduce the error by an obvious method of repetition. Unfortunately, however, the barometer rather aggravates what in the original apparatus is a sufficient trouble, namely, the liability of the apparatus to get out of order. However carefully it may have been constructed, the joints between the glass tubes and their sockets are sure to become leaky, and the capillaries between the laboratory and the volumeter are exasperatingly fragile.

McLeod [1869] (*C. J.* [2] 7, 314), and Thomas [1879] (*C. J.* 35, 218) endeavoured to remedy these evils, and to effect other improvements. For details see the papers referred to.

Infinitely handier than Regnault's unwieldy machine, though not quite equal to it in potential precision, is

Doyère's Apparatus.—(First notice dates from 1848. Full description in *A. Ch.* [3] 28, 1.) The essence of Doyère's system is that the measurement of the gases is effected in a plain graduated eudiometer, while a series of Ettling's gas pipettes serves for the chemical treatment of the gases, and their transference from vessel to vessel. The Ettling gas-pipette is depicted in fig. 5, and a glance at the figure suffices to show, in a general way at least, how the instrument is used for the transference of a gas from one tube to another; nor is it necessary to formulate the conditions or limits of its availability. The measurer (fig. 6) when in use is suspended over a pneumatic trough, deep enough to admit of the total immersion of the measurer, and is surrounded by a mass of water contained in a cistern whose sides are of plate-glass, while the mercury of the trough forms its bottom. To

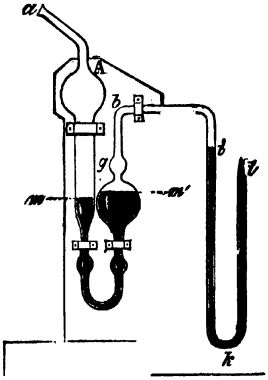

FIG. 5.

prepare the measurer for the reception of a gas, it is cleaned, slightly moistened inside, transferred to the trough by means of the portable mercury trap (fig. 7) fixed in the clip L, and filled with mercury by sucking out the air, by means of the U-shaped tube (fig. 8). The gas, which we will suppose to be contained in a gas-pipette, is then blown in, to be measured at a certain fixed disgregation, which is kept rigorously constant for the set of gas-quantities to be compared. A glance at fig. 6 at once suggests a mode of fulfilling this condition. But this mode is not Doyère's. He allows the temperature of the bath and the barometer to take care of themselves, but before each measurement he so adjusts the height of the water in the bath that the volume of a certain fixed quantity of air, shut up over water at a place within the water of the bath, assumes a certain fixed value, v_0. The standard body of air is contained in the '*Régulateur*' (fig. 9), a kind of air-thermometer which is fixed against a glass-plate, and, by it, suspended at a certain (by intention constant) height over the mercury-level of the trough. The water of the bath goes to some point B in the ascending branch of the capillary U-tube; BA is a thread of air; from A downwards there is a continuous mass of water, over which the standard body of air is shut up at R. Before each gas-measurement, the height of the water in the trough is so regulated (by means of taps) that meniscus A stands at some determined point of the scale, and the air which serves as regulator is consequently at some fixed volume v_0. This being done, the eudiometer is raised or lowered, until the height of the column of mercury suspended in it is at some fixed value, h_0. As a result, the gas is now practically at least, at a fixed disgregation.

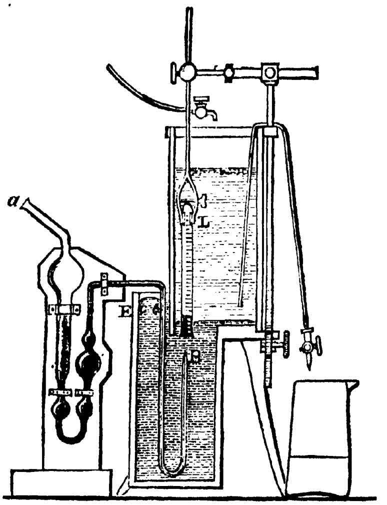

FIG. 6.

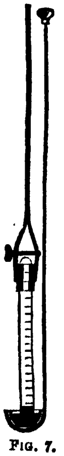

FIG. 7.

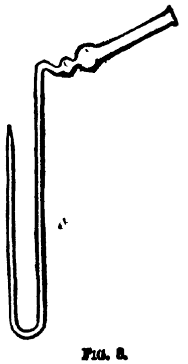

FIG. 8.

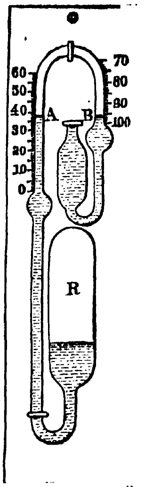

FIG. 9.

Proof. The pressure of the gas exceeds that of the air of the regulator by $\Delta+p_s+h_0$, where Δ stands for the height of B 'over' A (we refer to the regulator), and p_s for the height from the level in the trough to that in R of the regulator—both reduced to mercury. With a properly chosen h_0, the value $c=\Delta+p_s-h_0$, if not nil, is at least small, and nearly constant. Now supposing we have, for two successively measured quantities of gas, I. and II.:

	I.	II.
For the regulator-air	V_0, T'; P'.	V_0; T''; P''.
For the gas . . .	V'; T'; $(P'+c)$	V''; T''; $(P''+c)$.

As the regulator-air is at the constant volume, V_0, we have

$$\frac{T'}{P'}=\frac{T''}{P''}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad \text{I.}$$

The 'reduced volumes' (the Qs) of the two gases are

$$Q'=\frac{V'(P'+c)}{T'} \text{ and } Q''=\frac{V''(P''+c)}{T''} \quad . \quad . \quad . \qquad \text{II.}$$

and, as $\dfrac{c}{P' \text{ or } P''}$ is but small, we may write

$$\frac{Q'}{Q''}=\frac{V'}{V''}\left\{1+\frac{c}{P'}\left(\frac{P''-P}{P''}\right)\right\} \quad . \qquad \text{III.}$$

As both factors in the second term with the bracket $\{\quad\}$ are very small, we have practically,

$$\frac{Q'}{Q''}=\frac{V'}{V''}.$$

As the measurer is necessarily very small, the adjustment of h_0 must be made, and the gas-volumes read, with more than ordinary exactitude. Doyère accordingly provides a small short-vision telescope, which has a glass micrometer-scale (fig. 10) in its focus. The telescope is attached to a three-legged stand (which rests on a horizontal glass-plate fixed on the table close to the trough), in such a way that in all the necessary shiftings the optical axis remains parallel to, or when necessary, in, the same horizontal plane. To adjust h_0 the telescope is so focussed that it gives a distinct image of the mercury meniscus in the trough, which image is then made to coincide with line C-C′ (or BB′ if the telescope is an astronomical one). The eudiometer is then lifted or lowered until the image of the top of its meniscus touches the central line A-A′, which assigns to h_0 a definite, though unknown, value. This adjustment being made, the telescope is drawn backwards a little on the glass-plate to afford a good image of the eudiometer-scale, and to enable one to read the volume of the gas. The micrometer-scale serves to sub-divide the individual divisions on the eudiometer, which it does with an amply sufficient degree of precision. Before reading h_0 the eudiometer must be tapped to bring the mercurial meniscus into its normal shape.

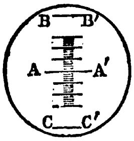

FIG. 10.

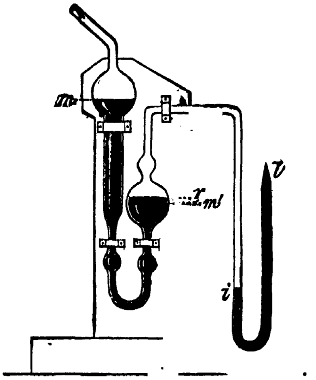

FIG. 11.

Assuming now that a gas, measured as described, contained carbon dioxide and air, and that we wished to determine the carbon dioxide by absorption with caustic potash. We begin by charging a gas pipette with mercury to about the extent shown in fig. 5. We then take the pipette to an auxiliary trough, immerse its U in the well, and, after having blown out the air, suck in the requisite quantity of caustic potash solution from a test-tube inverted over the trough, taking care *not to let any more mercury follow than is necessary* (practically) to trap the contents by a thread of mercury *i l*. We then transfer the pipette to the measurer containing the gas (as indicated in fig. 6), press down the measurer over the outer branch of the U, and transfer the gas from the measurer to the pipette, by sucking at *a*, until drops of mercury are seen to fall into the working bulb, *but no longer*. Things are now in the condition depicted in fig. 11, and all that remains to be done is to agitate the contents gently so as to insure absorption of the CO_2, and then to return what is left of the gas to the measurer. This, however, is a delicate operation, which in the hands of a beginner is not unlikely to fail. The first step is to replace the pipette under the measurer, to lower the latter sufficiently (*v. infra*), and to blow into the pipette so as just to dislodge the mercury thread *i l*. Supposing the pipette contains no more surplus mercury over and above that which was in it at the beginning, then as long as the meniscus in the eudiometer is below or at a level with that of the mercury in the trough, as it is underneath the bath, only part of the gas will pass out of the pipette into the eudiometer. The second step is to lift the pipette, so that its outflow end, B (fig. 6) or *l* (fig. 11), becomes visible within the gas-space of the measurer. As long as it is there, and the pipette is kept vertical, whether the gas flows out of B, or in at B, or remains at rest, depends mainly on the pressure of the gas in the eudiometer, and consequently on the altitude of the latter. But this altitude we have under absolute control. Hence what we have to do is carefully and slowly to lift the eudiometer until the thread of liquid reagent which makes its appearance as soon as the bulk of the gas is out, has come to, say, 2 mm. from the outflow end. We then stop sucking, put the pipette down on the table (which of course at once seals the end B with mercury), suck at *a* until we see mercury dropping into the pipette, take the pipette out of the mercury, and put it on the table to have it at hand for a repetition of the absorption.

The sequence of operations described is not quite so easy in practice as it looks on paper, because success depends largely on the permanence of the position of the pipette in reference to the plumb-line. Tilting over the pipette in the direction of the U means adding to the pressure of the gas inside; and *vice versâ*.

For the explosions, Doyère provides a special stout pipette, with fused-in platinum wires, &c.; but the method of combustion finds little favour in his eyes, because his apparatus does not readily fall in with its requirements.

In conclusion the writer may be permitted shortly to describe an apparatus of his own invention, which, thanks to the valuable assistance of Mr. Lennox, he was enabled to construct on his own premises, and which has since done him good service.

Dittmar's apparatus, like Doyère's, is based upon the Ettling gas-pipette. Apart from the necessary two troughs, it consists of the following three independent parts.

The *measurer* (fig. 12) is a combination of a wide with a narrow glass-tube, after the manner of Gay-Lussac's burette. The wide tube communicates by its lower contracted end

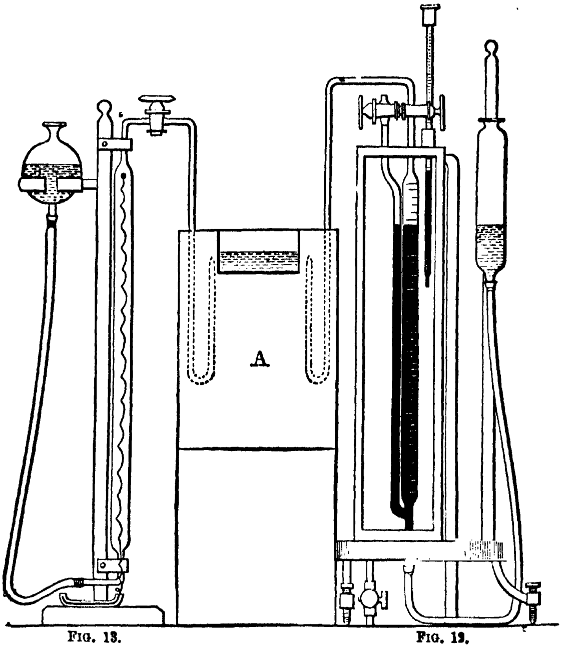

FIG. 13. FIG. 12.

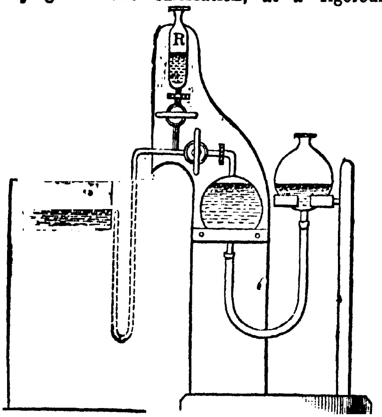

FIG. 14.

with a long capillary tube of india-rubber, and through it with a Geissler mercury-reservoir. At their upper ends both tubes are provided with Geissler stopcocks; to the exit-end of the wide tube is soldered the capillary U tube, characteristic of Ettling's pipette. The wide tube bears a mm. scale; the gas-volumes corresponding to the several marks are determined by gravimetric calibration, at a rigorously constant temperature, maintained by means of the water-bath. The narrow bit of tube between the top of the measurer and its stopcock is a capillary of the same bore as the U; it joins on quite abruptly to the wide tube, and the volumes are counted from the point of the junction, because, after the introduction of a gas, the narrow canal firmly retains its thread of mercury. The measurer holds a fixed position on the right side of a pneumatic trough, A, provided with two wells, one for the U of the measurer, the other for that of the exploder. In regard to the *exploder* (fig. 13), we have nothing to add to what is clearly seen from the figure, except the statement that the exploder in its present form is wider than the figure represents it to be, so wide, indeed, as to enable one to expand a gas considerably before exploding it.

The *absorber* in its original form is represented in fig. 14. For the interpretation of this fig. it suffices to say that R is a small mercury-reservoir which enables one to sweep out the thread of gas left in the capillary after the liquid reagent has been allowed to travel up to the safe side of the point of junction between the horizontal part of the capillary delivery tube and the stem of the reservoir. An improved form of the absorber (devised by Mr. Lennox) is represented in fig. 15.

To prepare the measurer for the reception of a gas, it is completely filled with mercury from the reservoir, the stopcock of the side tube is turned off as soon as all the air is driven out of it, and a drop of water is introduced into the main tube at a suitable stage.

The gas to be measured must be contained in a tube short enough to be within the range of the U: from this tube the gas is sucked into the measurer with the help of the reservoir, which is then adjusted so that the gas-pressure inside is about one atmosphere. The stopcock at the side tube is then opened, and the height of the reservoir is re-adjusted so that the menisci in the narrow and wide tube are in the same horizontal plane. A horizontal wire in the telescope facilitates this adjustment materially, but is not indispensable. The gas is now at the pressure $B + b - \pi$, where B is the height of the barometer, π the pressure of the vapour of water, and b the excess of the capillary depression in the narrow side tube as compared with that in the wider branch. The temperature is of course that of the water-bath. As both P and T oscillate with a series of measurements only within small amplitudes, it is expedient to reduce, not (for instance) to unit disgregation, but to some mean pressure and temperature (if there has been any variation in either or both) by means of some suitable formula, such as:

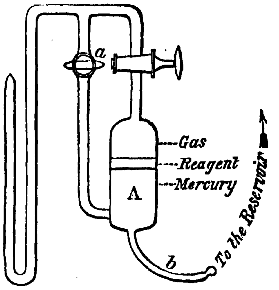

FIG. 15.

$$V_0 = V\left\{1 + \frac{(\Delta P)}{P_0} - \frac{\Delta T}{T_0}\right\}$$

where P_0 and T_0 stand for the standard values, and the observed values are assumed to be greater than these by (ΔP) and (ΔT) respectively. If a table of the reciprocals of the practically occurring Ps and Ts is at hand, the calculation becomes so very easy that it is not worth while to set up a disgregation indicator.

Technical Gas-Analysis.

To meet the demands of chemical industry there has been invented a variety of methods for the rapid, though perhaps only approximate, analysis of certain classes of gas-mixtures. The methods all agree in this, that the use of mercury is dispensed with, the gases being measured over water, or even perhaps over the respective absorbent solutions. The Bunte *Gas-burette* may be quoted as a typical example of this class of apparatus. Imagine a long cylindrical pipette graduated for gas-volumes and provided with a stop-cock at each end, and combinable with a reservoir by means of a long india-rubber tube. To analyse, say, a chimney-gas, the burette is filled with the gas by displacement, and the reservoir, after having been filled with water, is attached below. By placing the reservoir at a certain convenient altitude, and temporarily opening the upper cock, a certain volume of the gas is shut off at the pressure of one atmosphere. In order now to determine the carbonic acid, we suck out the water by an (easily imagined) auxiliary apparatus, and replace it by a solution of caustic potash, which is shaken with the gas. The caustic potash is then sucked out, water is let in, the original pressure is re-established, and the residue is measured. In a similar manner, the oxygen is determined by absorption with alkaline pyrogallate.[1]

ANALYSIS BY THE METHOD OF TITRATION.

This branch of analysis comprises the applications of what was described in a previous section as the *titrimetric method of indirect weighing*. The method in any of its present forms is applicable only to such reactions as proceed readily in aqueous solutions; the reagents, accordingly, are always used in the form of *standard solutions* (*liqueurs titrées*), *i.e.* solutions the strengths of which are known in reference to the process under consideration.

The amount of standard solution required in a *titration* may be measured either by weight or by volume; in either case the measurement of the solution is only an indirect mode of weighing the active agent contained in it. The gravimetric method is certainly susceptible of the higher degree of precision; yet the volumetric method is universally preferred, because it is by far the more handy and expeditious of the two, and, if properly conducted, (with very few exceptions) does ample justice to even the best titrimetric processes.

The invention of volumetric analysis must be credited to Gay-Lussac. Long before him, it is true, Stirling enunciated the principle of the method, and Vauquelin and Descroizille used it for assaying commercial alkalis; but to Gay-Lussac undoubtedly belongs the credit of being the first to bring the method into an exact form, and to work out all its technicalities in the most masterly manner. Volumetric analysis was slow in progressing. Gay-Lussac's more immediate successors, misled by his success in regard to silver, directed their attention almost exclusively to the translation of established gravimetric into volumetric methods; failing to see (what is now so obvious) that the number of reactions to which both methods are applicable must necessarily be very limited.

Very little real progress was made until 1856, when Bunsen, by introducing a new idea, gave a fresh impetus to investigation. Starting from the well-known reaction which takes place when iodine solution is dropped into aqueous sulphurous acid (and which Langlois had already utilised for the determination of this substance), he established the conditions under which the process takes the precise course indicated by the equation; and on the basis thus gained he developed exact methods, not only for the direct determination of these two bodies, but also for the indirect determination, by means of the same two solutions, of a whole series of oxidising agents, for which an equivalent of iodine can be substituted by the purely qualitative execution of certain reactions.

---

[1] Professor Winkler, of Freiberg, has made a special study of this branch of gas-analysis, and has written two excellent books on the subject; one of these has been translated into English by Professor Lunge. To these books and another we refer for further information. (1) Dr. Clemens Winkler, *Anleitung zur chemischen Analyse der Industrie-Gase* (Freiberg, Engelhardt, 1876). (2) An abridged edition of the same by the author. Translated by Lunge (Van Voorst, London). Also, *Neue Methoden zur Analyse der Gase*, von Walter Hempel (Braunschweig, Vieweg u. Sohn, 1880).

By this memorable research volumetric analysis found its true sphere of action, as an invaluable means for the determination of *generic* radicles, such as the active oxygen in peroxides, the loosely held chlorine in perchlorides, the replaceable hydrogen in acids, the oxygen or chlorine-equivalent of reducing agents; for a host of determinations, in short, which practically lie outside the range of the gravimetric method. Where the two methods compete in the solution of the same problem, volumetric analysis generally offers the advantages of greater promptitude and facility of execution; it, indeed, stops where with gravimetric analysis the most difficult part of the work would begin. This advantage, however, is not an absolutely clear gain. The volumetric method, so to say, does not look at the *body* to be determined, but, in a somewhat blindfolded way, only measures one of its chemical properties, which in no case appertains to that body only; hence errors are more likely to be overlooked, and are far more difficult of subsequent correction, in volumetric, than in gravimetric, analysis; for gravimetric analysis furnishes the thing to be weighed in the form of a definite compound, which can be examined for its purity, and, if necessary, be purified before it is weighed. A small amount of iron, nickel, zinc, &c., which has escaped precipitation may be searched for in the filtrate and recovered; any deficit or excess obtained in a titration is thrown away with the rest of the products.

We have no space for a full history of our subject; yet we must not forget to give credit to the late F. Mohr for having contributed largely to the modern development of volumetric analysis, by his criticisms of old, and his invention of new, methods; by the construction of useful apparatus; and last, not least, by the compilation (for the first time) of an original and comprehensive handbook[1] on the subject.

In now passing to the systematic exposition of our subject, we will begin with a few remarks on the

Graduated Glass Measures

which serve for the preparation of the standard solutions, and the necessary measurements of liquids generally. Volumetric analysis of course involves only comparative measurements; we indeed never measure a standard solution otherwise than in reference to itself; hence the unit of volume may not only be chosen at pleasure, but need not bear any known relation to the unit of weight. But the only correct mode of gauging a liquid measure is to determine the weight of water it holds (or delivers); hence for those who are in the habit of using the gram as their unit of weight the most convenient unit of volume is the volume at (let us say) 15°C. of that mass of water whose *uncorrected* weight in air is one gram. We might herewith adopt this unit and call it the '*fluid gram.*' In doing so we should not be guilty of any innovation. The customary unit with most chemists and instrument-makers, it is true, is the *cubic centimetre*, but it is this only nominally; the actual unit in almost all commercial '*cubic centimetre*' measures comes nearer to our fluid gram than to the nominal unit. From what we have said, the reader will understand that if in the sequel we speak of *cubic centimetres*, or *litres*, these terms mean only *unit-volume*, and 1000 *unit-volumes*, respectively, unless it is clear from the context that we mean to approximately define an absolute quantity, or to refer to the well-known relation between the *litre* and the *kilogram*.

As all aqueous liquids wet glass, the mark on a *litre flask*, &c., can be correct only in reference to a specified mode of reading. The best mode is this. Place the vessel so that its axis is vertical, and look at the meniscus horizontally with one eye. The meniscus then appears as a flat crescent-shaped strip. The lower boundary of this strip is taken as the line of reference, and the real, or imaginary, mark on the graduation with which it coincides (visionally) is taken down as the *reading* of the liquid. The line referred to gains in sharpness of definition if it is observed in transmitted light, and a strip of black paper is fixed to the back of the measure about 2–3 mms. below the line. With only one of the customary standard solutions, namely the almost opaque solution of permanganate of potash used for iron titrations, this mode of reading does not work. In the case of this liquid we must take the upper boundary of the meniscus as our reference mark; this upper boundary assumes its maximum definition if viewed in reflected light, and with a white background (a piece of paper) immediately behind it. Any reading made in this exceptional manner is of course subject to an obvious correction, the amount of which is ascertained by measuring the height of the meniscus of a transparent solution in the same vessel. In most cases, however, the volume to be determined is the difference between two consecutive readings, so that the correction in question becomes unnecessary.

In a vessel which serves for measuring out a certain volume, the small quantity of liquid which permanently adheres to the glass must be allowed for by the maker, *i.e.* the scale must be constructed so as to include what would otherwise be a necessary correction. In the case of graduated pipettes this can of course be done only on the basis of a conventional mode of emptying out, which, when once fixed upon, must be rigorously adhered to. The thermic expansion of glass may unhesitatingly be neglected in the graduation of a titrimetric measure. A glass flask which holds 1000 c.c. at 15°C., at 15 ± 10° holds 1000 c.c. ± 0·27 c.c.; *i.e.* only $\frac{1}{4000}$th more or less. The thermic expansion of the solutions measured is far more considerable, and cannot in all cases be neglected. We shall come back to this point in the next section.

The chemist now-a-days has no occasion to graduate his own burettes, litre-flasks, &c., but he should never use a set of instruments—although they come from the most famous maker—without having first tested them. The following is the method to be pursued. Passing from measure to measure, and with each measure from mark to mark, measure in or out the several marked off volumes of pure water of known temperature, and determine their weights in grams. In the case of apparatus with a running-on scale, only every 10th or 20th mark need be checked in this manner, unless there are visible irregularities in the graduation. After having thus gone through the whole system, reduce all the water-weights to the same temperature, say to 15°C. (*i.e.* from the observed weight of water of $t°$ calculate the weight of water of 15° which fills the same space); divide each corrected weight by the corresponding nominal volume, to find the weight-value of the actual unit—and draw your conclusions. Supposing the several units agree fairly, select a suitable average value (not necessarily the mean, because the numbers are not all of the same weight mathematically) as *the* unit, and calculate the volumes corresponding to the several marks in terms of this adopted unit. The results ought, by theory, to agree with the respective nominal values, but in practice, of course, we cannot expect absolute coincidence. In a burette, for instance, which gives $\frac{1}{5}$ c.c.s directly, we must tolerate ±0·1 c.c., and with the lower marks, even a little more. Whether the actual unit is, or is not, equal to the nominal is of no consequence; yet, if it is not, it is obviously advisable to note down its value—in fluid grams or c.c.s—for future reference.

---

[1] Mohr, *Lehrbuch der chemisch-analytischen Titrirmethode*. The first edition dates from 1857; the fourth and last from 1886.

To facilitate the calculations involved in such work as the graduation of instruments, the writer many years ago calculated the following table:—

A mass of water, which, in air of t°C., and 760 mm. pressure, balances a brass kilogram weight, at t°C. occupies $(1000 + x)$ *fluid grams* = $(1000 + y)$ *true cubic centimetres.*

$t°$	x	y	$t°$	x	y
+0°	−0·64	+1·25	+15°	+0·00	+1·89
4	0·78	1·12	16	0·15	2·04
8	0·68	1·21	17	0·30	2·20
9	0·63	1·27	18	0·47	2·37
10	0·56	1·34	19	0·66	2·55
11	0·47	1·43	20	0·85	2·74
12	0·38	1·52	21	1·06	2·95
13	0·27	1·63	22	1·28	3·17
14	0·14	1·76	23	1·51	3·39
15	0·00	1·89	24	1·75	3·63

Preparation of Standard Solutions.

In fixing upon the degree of concentration for a specified standard solution, we may allow ourselves considerable latitude. As a rule the nature of the volumetric process for which the solution is to be used may be left out of account; all we need look to is that the probable inherent error of the method corresponds to a distinctly visible difference of level in the burette; say to 0·1 or 0·2 c.c. according to the size of the 'c.c.' With methods possessing a very high degree of inherent precision this rule would lead to an inconveniently dilute reagent. In such (rare) cases we help ourselves by supplementing a moderately dilute standard solution with a *decimal solution*, meaning a solution prepared by diluting the reagent proper with water to 10 times its volume. The decimal solution serves only to finish the titration which has already been almost completed by means of the standard solution proper. This system of course is a mere delusion unless the stronger solution be measured with at least 10 times the precision attained with the decimal one.

The strength of any given solution should be so defined as to reduce the subsequent calculations to their highest degree of simplicity. Supposing, for instance, we have to deal with a standard sulphuric acid intended for the measurement of alkalis; evidently it would not be expedient to note down the number, n, of grams (or mgms.) of H_2SO_4 or SO_3 which is contained in each litre (or c.c.) of the reagent. As the number when calculated into KHO, NaHO, Na_2CO_3, &c. has always to be divided by $SO_4H_2(=98)$ or by $\frac{1}{2}H_2SO_4(=49)$, it is obviously better to calculate the value $\frac{n}{49} = \tau$ (as a decimal) and put down this τ as the strength of the solution. Were the solution intended exclusively for the determination of soda, to be reported as Na_2O, it would be still better to calculate the value of $\frac{n \times Na_2O}{H_2SO_4} = \tau'$, and note down the weight τ' (of sodium monoxide) as the strength of the reagent.

For the standardisation of a specified solution we have in general the choice between two methods; (1) a quantitatively exact synthesis; (2) an approximate synthesis, followed by an exact analysis. The first method may assume one of two forms; we either weigh out exactly so much of the pure reagent, dissolve it in water, and dilute to, say, 1 litre; or else (if the pure reagent is not itself at hand) we analyse, say, a strong solution of the pure or impure reagent, by means of some very exact method, and synthesise directly on the basis of this determination. In regard to the second method, the first step of course is to procure an approximately correct solution. For example, let us assume we wish to prepare a standard hydrochloric acid containing exactly HCl = 36·5 grams per litre. An apology for such a solution might be obtained from the ordinary (pure) laboratory acid, by determining its specific gravity, deducing the percentage, and synthesising on the basis thus gained. In all such cases it is expedient to so allow for the uncertainty in the assumed percentage that the solution obtained is sure to be *stronger* than intended. In accordance with the rule, let us assume the actual strength, as found by analysis, to be p, instead of the intended strength p_0, and let $p > p_0$. Obviously our 'v' litres of reagent must be diluted to $\mathrm{v} = \frac{vp}{p_0}$ to bring the strength down from p to p_0; the liquid must not be diluted with $v\left(\frac{p}{p_0} - 1\right) = w$ litres of water, because the two liquids when mixed would contract, and a little more than w litre, say $(1 + \epsilon)\,w$ litre, of water would be necessary to bring up the volume to the intended value, v. In practice, however, large volumes (such as we assume our v and v to be) cannot be measured with adequate precision, so that the second (theoretically faulty) method is generally the better of the two. It certainly is the better if the required correction is only small; if for instance $\left(\frac{p}{p_0} - 1\right)$ is something like 0·03 or less. In such a case, if only

w as calculated is measured accurately, the corrected solution will be as near the intended strength, p_0, as the given solution was near its strength p.

As an example, let us take $\frac{p}{p_0} - 1 = 0{\cdot}03$; $v = 10$ litres; $\delta v = \pm\ 0{\cdot}5$ litre (which is a liberal allowance); and we have

$$\frac{\delta p_0}{p_0} = \frac{\delta p}{p} \pm 0{\cdot}0015.$$

Even in such a case it is only prudent again to analyse the corrected solution, to see that no blunder has been made. Supposing (to return to the example) the number p had been the result of three well-agreeing analyses, the intended value for p_0 had been 37·00, and the analysis of the corrected solution had given for p_0 the value 36·84; the most probable value for the actual strength would be $(3 \times 37{\cdot}0 + 36{\cdot}84) \div 4$.

Turning back, let us now assume $p_0 > p$. In this case our v litres of solution should be reduced to $\frac{p}{p_0} v$ litres, by elimination of $(1+\epsilon)\ (1 - \frac{p}{p_0})\ v =$ '$(1+\epsilon)\ w$' litres of water. Even where evaporation would be permissible, it is better to compensate for the surplus water by addition of the substance which served to make the solution. Supposing we had used s grams of substance for every 1 litre of reagent produced. Clearly $\frac{p_0}{p} s = s_0$ grams is what ought to have been taken. One way then is to prepare some (say ½ litre) of the solution by means of the corrected method and to determine its specific gravity, π_0, in order to be able to reduce to weight; thus:

1 litre of solution (p_0) . . . $= 1000\ \pi_0$ grms.
Weight of substance in it . . $= s_0$
Hence weight of the water . . $= 1000\ \pi_0 - s_0$

Or every gram of water requires

'c' $= \frac{s_0}{1000\ \pi_0 - s_0}$ grms. of substance to be converted into solution of the intended strength, p_0; hence our $v \times (1-\epsilon)\ w \times$ kilos. of water require $v \times (1+\epsilon)\ wc \times$ kilos. of substance. All that we need for the calculation of $(1+\epsilon)w$ is the specific gravity π of the uncorrected solution. Obviously $(1+\epsilon)w = 1000(\pi - \frac{p}{p_0}\pi_0)$ grams. In practice, however, it is scarcely advisable to go to all this trouble. It is easy by some short cut (based on the above) to name a number of grams of substance, which if added to one litre of solution would bring up the strength to a little above p_0. Suppose the increase of volume involved in adding these grams of substance is less than, say, 0·1, 0·2..., say y litre. Then, to set things right, we calculate the correct mass of substance for $1+y$ litres, which is $(1+y)\ \frac{p_0}{p} s$, weigh out what this mass is more than the s grams present, in each litre, add this to each litre of solution as given, and dilute to $1+y$ litre by addition of water. If p differs much from p_0, it is expedient to slightly over-correct the solution, to determine the exact value, p', which the solution now has, and (if $p' > p_0$ as intended) to correct the strength, by dilution, as explained above. If p is only a little less than the intended value p_0, we may safely assume the surplus water per litre to be $1 - \frac{p}{p_0}$ litre, and add the exact weight, x, of substance, which by calculation converts the small quantity of water into correct solution. The result (in the absence of blunders) will be quite correct even if v was only approximately measured, because a very small volume of water added or withdrawn from the total of v litres would make the solution absolutely correct (apart from the error in p of course). One point remains to be considered. Supposing the strength of a solution at t_0 degrees is p_0, what is the strength p_1 at t_1 degrees? It would not do to calculate the correction from the expansion of pure water from t_0 to t_1, because all standard solutions expand more largely than pure water does. A correct method is to determine the specific gravity (say the weight contained in a narrow-necked 100 c.c. flask) of the solution at t_0 degrees and at t_1 degrees. Supposing the weight of it is π at t_1 and π_0 at t_0, we have $p_1 = \frac{\pi_1}{\pi_0} p_0$.

This correction of course is indicated only in the case of very exact methods. But in their case it is best altogether to eliminate the uncertainties of volume-measurement by effecting the final standardisation by volume and by weight at the same time; by determining for instance at the same time the weight in grams and the volume in c.c.s of the quantity of standard nitrate of silver which is required for the exact ppn. of (say) $\frac{KCl}{100}$ grms. of pure chloride of potassium. This need not hinder one in so adjusting the solution that the quantity referred to may for all ordinary purposes be assumed to be equal to 100 c.c. For the purpose of a highly exact determination, the bulk of reagent (*e.g.* $AgNO_3$ solution) required, after having been measured out, is weighed into the (chloride) solution to be analysed, and the small excess of substance or reagent left is determined by volumetric titration with decimal solutions.[1]

The adjustment of an analytically standardised solution to an exact pre-determined strength is advisable only if the solution is permanent, and is meant to be used very frequently, otherwise it is better to note down the strength as it is, and calculate from it. A solution known to contain $1{\cdot}023 \times HCl$ grams per litre is almost as convenient as one containing $1 \times HCl$ exactly. Because for one or two analyses we can well afford to calculate, say, the product $1{\cdot}023 \times \frac{Na_2O}{2}$, and for a very long series of such determinations the value may be calculated once for all and noted on the label.

On the Theory of Titration.

Let A and B be two chemical species, which, when their solutions are mixed together, combine with, or decompose, each other in some definite manner. Is the reaction available for the mutual volumetric measurement of A and B, or (let us rather say) for the measurement of A by B? It *may* be if, under easily realisable conditions, it proceeds rapidly, and, if it is possible under these conditions to recognise the *point of saturation* with sufficient sharpness, *i.e.* the point from which onwards an additional drop of B-solution does not produce a recognisable change. In some cases the point of saturation defines itself naturally by coinciding with some sudden visible change, *e.g.* a change of colour. It does so, for instance, if the reaction is a double decomposition, $a+b=c+d$ (where a, b, c, d, stand for definite relative quantities of the reagents A or B, and the products C and D respectively), and if A (or B) is intensely coloured, while B, C, and D (or A, C, and D) are relatively colourless, or at least do not hinder the observation of the colour of the last remnant of A, or a slight excess of B.

---

[1] Compare Dittmar's *Memoir on the Composition of Ocean Water*, 'Challenger' Memoirs, page 4; also his *Exercises in Quantitative Analysis*, section on *Sea-water*.

Examples: 1, Oxidation of ferrous salt (A), by permanganate (B), with formation of ferric salt (C), and manganous salt (D).—2. Decolourisation of the intensely blue solution of cupric-ammonium salt (A), by the reducing action of (standard) cyanide of potassium (B), with formation of colourless double cyanide of copper and alkali metal (C), and cyanate and other salts of alkali (D).

Sometimes when such colour-changes do not occur, they may be produced by addition to the solution to be titrated of a suitable *indicator.* Thus: 1. Litmus solution may serve as an indicator in the volumetric neutralisation of acid by alkali (or *vice versâ*).—2. Iron-alum may serve as an indicator in the determination of silver (salt) by added sulphocyanide of ammonium, the red colour of $Fe(NCS)_3$ becomes permanent only when all the silver has been ppd. as AgNCS, and a slight excess of sulphocyanide has been added. The indicator in this case would evidently be of no use if it were not the case that $Fe(NCS)_3$, which is produced locally from the first, is decomposed as readily and in the same way by silver salt as the alkaline sulphocyanide is. A similar remark applies to indicators generally. If an indicator, while otherwise trustworthy, fails only to fulfil the condition stated above, it may still be available in the sense that, instead of adding it to the 'A'-solution from the first, we may apply a little of it to drops of the mixture taken out at suitable stages in the process of the reaction. Thus, for instance, in the titration of phosphate (A), by uranic acetate (B), prussiate of potash may serve as a *drop-reagent*, because, although unavailable as an indicator proper, if added to a drop of the mixture it produces the red-brown colour of ferrocyanide of uranium only if the uranium is present as (an excess of) acetate; the uranic phosphate is not decomposed by the prussiate. The action of an indicator need not necessarily consist of a colour-reaction; a ppn. if sufficiently delicate, is as good in principle, though not as a rule in practice because the locally-formed characteristic pp. will not disappear so readily on stirring up as the colour of a dissolved product would.

If the reaction is a steadily progressing ppn. of the essential radicle *a* in A by B, the end of the reaction of course coincides with the completion of the ppn., *i.e.* the point when (supposing B to be added in successive drops) the last remnant of *a* has just been thrown down by the n^{th} drop of B, so that the $(n+1)^{st}$ drop fails to give a turbidity. For such reactions we need no indicator or drop-test, although such may be very convenient.

As soon as we have found some means for recognising the end-point in our reaction with sufficient sharpness, we can decide the question as to its availability by preparing standard solutions of A and B respectively, and determining the ratio $a:b$ corresponding to the end-point under a sufficient variety of conditions. In a first series we work with the plain solution, but take care in one set of trials to begin with A and drop in B until the reaction is apparently completed; and in another set of trials we begin with B, pour in a slight excess of A, and then finish with B; this is done in order to see whether the ratio $a:b$ is independent of the mode of mixing. In a second series, we add known, but varying, proportions of water. In a third series we add more or less (but always a known weight (x) of this or that body X which in the practical application of the method would be likely (if not sure) to be present, &c. From Series I. and II. we easily calculate the small excess of reagent B which must be added, per F c.c. of total mixture at the end, to produce a visible end-reaction. We then calculate for each trial the value $K = \frac{V_b - \beta F}{V_a}$, and see whether there is a practically sufficient and available area of experimental conditions within which the ratio $a:b$ has a constant value. Or, what comes to the same thing, we take the mean of all the Ks (let it be $=K_0$), and see whether the values of V_b as calculated by the equation $V_b = K_0 V_a + \beta F$ agree sufficiently with the directly observed values. Should this not be the case, the process need not necessarily be given up as hopeless; it may still remain worth while to see whether agreement between theory and practice cannot be established by adding a term cx to the right side of the equation, where x stands for the weight of some subsidiary component X, and c is a positive or negative constant, whose value must of course be experimentally ascertained. In such cases, however, it is better to leave the chemical significance of K_0, β, and c, entirely on one side, and to calculate them as so many empirical coefficients from the sum-total of the results. A formula thus obtained is of course of no practical value unless β and c are so small that an approximate determination of F and X suffices for an exact calculation of the respective terms. As an illustration we may quote Liebig's method for the determination of urea (A), in presence of chloride of sodium (X), by means of standard mercuric nitrate (B) as a pptnt. of the urea, and carbonate of soda as a drop-test for excess of pptnt. The exact volume V_b of mercuric nitrate solution (*i.e.* weight of HgO) to reach the end-point for a given weight (a) of urea, varies with the dilution, F, and the weight X of salt present; but V_b is[1] in sufficient accordance with equation $V_b = ak + \beta F + cx$, whose constants have been determined (virtually) by Liebig.

Nothing said so far is based on the presumption that the exact chemical theory for the reaction between B and A is known. There are indeed a number of useful volumetric processes which are based upon unexplained, or only half-explained, chemical reactions. Fehling's method for the determination of glucose affords an illustration. If a dilute solution of glucose is dropped into a hot, strongly alkaline, solution of tartrate of copper (CuO) and potash, the CuO is reduced to (a pp. of) Cu_2O, the blue colour of the solution disappears, and the sugar suffers some unknown kind of oxidation. Yet the ratio between (say) dextrose oxidised and copper-oxide reduced, under specified conditions, is fairly constant, and the reaction is accordingly available for a fairly exact method for the determination of dextrose.

---

[1] Or at least is supposed to be.

The well-known process of Clark for the determination of the hardness of a water by means of standard soap might be quoted as another example. But such purely empirical processes, however useful they may be for this or that practical purpose, are of little importance as auxiliaries of exact analysis, which demands of a titration-process in the first instance that in any given case the question of its applicability can be decided *a priori* with at least a high degree of (if not with perfect) certainty. And this is possible only if the process is based on a definite chemical equation which gives a qualitatively and quantitatively exact account of what is going on.

From the fact, however, that some equation, $a+b=c+d$, is in itself a correct theory of the action of A on B as resulting in the products C and D, it does not follow that the equation is a sufficient theory of the corresponding process of titration. Because experience shows that, in general, ready-made C and D when mixed together produce A and B in accordance with the inverse equation $c + d = a + b$. Hence supposing we start with a parts of A and add more and more of B, the *end reaction* is reached only when a part (say qa) of A is transformed at the expense of qb parts of B, while $(1-q)$ times $(a+b)$ are still present in their original condition. Generally, q is a continuous function of the experimental variants (state of dilution, temperature, &c.), and the translatability of the reaction into a titrimetric process depends on the possibility of finding a sufficient area of conditions within which q is, at least practically, equal to unity.

If one of the products (C and D) separates out as an absolutely insoluble pp., or escapes as a gas, the reverse reaction does not occur, and q becomes equal to unity; the *apparent* end-point is the *real* end-point of the reaction. Hence we should think that ppns. (we mean cases where that radicle in A which is really the thing to be determined, by uniting with the essential radicle in B, separates out as a pp.), should be pre-eminently suitable for volumetric application. Experience, however, shows that the reverse is true. Because in the majority of cases the pp. carries down more or less of one or other of the other reagents or products, and so disturbs the quantitative relations. Very often also a considerable excess of pptnt. is required to produce complete ppn. within a reasonable time. Both difficulties (for example) present themselves in the case of that reaction, $BaX + SO_4R_2 = R_2X + BaSO_4$, which is so largely used for the gravimetric determination of SO_4 and of Ba. The irregularities referred to[1] can be set right (more or less easily) in the gravimetric application of the reaction; to the volumetric application they are absolutely fatal. The number of ppns., indeed, which afford a basis for correct volumetric processes is extremely limited.

Certain classes of double decompositions and oxidations, in which reverse reactions are prevented by the great inherent stability of one of the products, are admirably adapted to volumetric processes. To give examples:

Any strong acid, XH, when mixed progressively with a solution of some strong base of the type ROH (ex. $KHO, NaOH, Ba(OH)_2$), is ultimately converted into normal salt, XR, with formation of that highly stable substance water. The general reaction is $XH + ROH = RX + HHO$, and the end-point can in all cases be sharply defined by means of a few drops of neutral litmus-solution as an indicator. Hence any acid (or rather the 'H' in any acid) may be accurately measured by means of a standard solution of, for instance, caustic potash; and any of the bodies ROH (or rather their 'OH') by means of a standard solution of (say) hydrochloric acid. The latter method applies almost directly to the (soluble) carbonates, sulphides, cyanides, &c., of the alkali metals. All the carbonates &c. referred to can be measured indirectly by the combined application of the two standard solutions: we add first an excess of standard acid, and heat to expel the volatile acid (CO_2, H_2S, &c.), then colour with litmus, and titrate back with standard alkali, till the point of neutrality is exactly reached. By substituting *aurine* (in alcoholic solution) for litmus, the method becomes available also for magnesia (Tornö); and by using nitric acid as the standard XH, we can determine even oxide of silver (Dittmar).

What we said of carbonates, &c., in reference to the metallic radicles, R, holds for the ammonium salts of our acids, XH. To determine, for instance, HCl or H_2SO_4, in the presence of ammonia (as the only base), we need only add a known excess of standard alkali, expel the liberated ammonia by evaporation, then add litmus, super-saturate by standard acid, boil off the carbonic acid, titrate back with standard alkali until the point of neutrality is exactly reached, and balance the equivalents of base and acid used as reagents, against each other; the balance of base-equivalents measures the acid given for determination.

That this method of acidimetry applies also to cases where the base can be separated out by excess of standard alkali, as an acid-free pp., is obvious. Oxide of copper (given as $CuSO_4$ or other cupric salt) fulfils this condition in the sense at least that the acid ppd. at first as part of a basic salt, can be re-extracted by boiling with excess of alkali.[2]

---

[1] And other irregularities such as for instance the variability of the ratio of sulphur to copper in ppd. sulphide of copper.

[2] We will avail ourselves of this opportunity for referring to the process of fractional filtration as useful in

To pass to another example. There is a series of reducing agents R, the solutions of which, when mixed with a solution of iodine in iodide of potassium, are oxidised into products R′, while the corresponding quantity of free iodine passes into iodide.

For example:—

$$\left.\begin{array}{rl} \text{I.} & SO_2 + H_2O + I_2 = 2HI + SO_3 \\ \text{II.} & 2S_2O_3R_2 + I_2 = 2RI + S_4O_6R_2 \\ \text{III} & As_2O_3 + 2H_2O + 2I_2 = 4HI + As_2O_5 \\ \text{IV.} & Sb_2O_3 + 2H_2O + 2I_2 = 4HI + Sb_2O_5 \\ \text{V.} & SnCl_2 + 2HCl + I_2 = 2HI + SnCl_4 \end{array}\right\} \text{in solution.}$$

Each of these reactions takes its normal course only under certain conditions, which, however, in cases I. to IV. at least, are easily established. All go on readily in the cold; and with all, starch solution is a safe and delicate indicator of excess of free iodine. Hence, to determine any of our reducers, R, we bring it into solution in the proper manner, add starch solution, and then drop in iodine solution from the burette until the blue colour of iodide of starch, which appears locally from the first, becomes permanent on stirring. Supposing t c.c. of iodine solution to have been used, and one c.c. of it to contain $\tau \times 127$ mgms. of free iodine, the weight of R is $t\,\tau$ ($\frac{1}{2}SO_2$, S_2O_3, $\frac{1}{4}As_2O_3$, $\frac{1}{4}Sb_2O_3$, $\frac{1}{2}SnCl_2$), as the case may be. By theory, any one of our reducers might serve as a reagent for the measurement of free iodine; in practice sulphurous acid and alkaline thiosulphate work best.

According to Bunsen, sulphurous acid acts normally on iodine, if it is diffused through at least 3,000 times its weight of (air-free) water. For the determination of free iodine he uses an aqueous sulphurous acid diluted to the extent stated, in combination with a standardised solution of iodine. The sulphurous acid is measured out by means of a glass-stoppered cylinder (or a narrow necked flask with one mark on the neck) holding some 100-200 c.c. To determine an unknown weight (x mgms.) of free iodine given as solution in HI or KI solution, we add the least number n of measures of the sulphurous acid water which suffices to decolourise the solution, then starch solution, and lastly, from the burette, standard iodine, until the blue colour becomes permanent after addition of, let us say, t c.c. On the other hand, we ascertain the number, t_0, of c.c.s of standard iodine required for 1 measure-full of the sulphurous acid. Obviously, $nt_0\tau \times 127 = x + t\,\tau \times 127$ (mgms. of I_2). Whence $x = (nt_0 - t)\ \tau \times 127$.

So far Bunsen had done no more than translate an old process for determining SO_2 into a precise method for determining iodine. His great merit was to see that, given a method for determining free iodine, we have an indirect method for the determination of any of the large number of oxidising agents for which a definite proportion of iodine can be substituted by the purely qualitative execution of suitable reactions. Thus, for instance, we may determine free bromine, iodate RIO_3, bromate $RBrO_3$, hypochlorite $RClO$, ozone O_3, by letting the respective substance act on excess of iodide of potassium solution, acidifying with hydrochloric acid, and then titrating the iodine liberated as above explained.

From the respective equations, we see that Br_2, or Cl_2, or $RClO$, or O_3, liberates I_2; and that RIO_3 or $RBrO_3$ liberates $3I_2$.

The same principle obviously applies to all those peroxides which, when distilled with excess of hydrochloric acid, liberate a definite proportion of chlorine. As examples: $MnO.O_x$ (when distilled with HCl) yields $x \times Cl_2$ of free chlorine, which when passed into iodide of potassium solution liberates $x \times I_2$ of iodine. Hence for every one I mgm. obtained, there was $\frac{1}{2x} \times (MnO.O_x)$ mgms. of *that* peroxide of manganese. And similarly (to quote another case which is known to work) every CrO_3 mgm. of chromic trioxide, liberating $3 \times Cl$, ultimately yields $3 \times I$ mgms. of iodine; or, in this case, every $1 \times I$ mgms. corresponds to $\frac{1}{3}CrO_3$, or to $\frac{1}{6} \times K_2Cr_2O_7$ if the CrO_3 was present in this form. It is as well to mention that what the method in any case really determines is, not the respective species, but the I_2-yielding radicle; the active oxygen in the $MnO.O_x$, or the $Cr_2O_3.O_3$, or $RClO$; the O_3 in the KIO_3; the *one* O in O_3, &c.

The applicability of the general method, however, goes further. As ferrous chloride is readily converted into ferric salt by free chlorine, we can determine an unknown weight of *ferrosum* (ferrous iron) (given as $FeCl_2$, FeO, $FeSO_4$, &c.) by distilling the respective substance with a weighed excess of potassium dichromate and hydrochloric acid, and collecting the chlorine in iodide of potassium, &c. Supposing we used $k \times K_2Cr_2O_7$ mgms. of this salt, the chlorine furnished by it is $6 \times k \times Cl$ mgms., and, if the iodine obtained at the end was $(nt_0 - t) \times \tau \times I$ mgms., then $6k \times Cl - (nt_0 - t)\tau Cl$ must have been used by the $FeCl_2$, and consequently, $\{6k - (nt_0 - t)\tau\} \times (Fe = 56$ mgms.) of ferrosum must have been present in the substance analysed.

Strictly speaking, all volumetric methods are empirical methods, in this sense, that the fundamental chemical equation is only an approximate theory of the process. Hence, unless we are sure that the error in the equation, considered as a theory of titration, is less than the unavoidable error involved in the operations, to attain the highest possible degree of precision we must standardise our measuring reagent (if possible) by means of a known weight of the very thing (or radicle) to be determined, and both in the standardisation and the analyses we must maintain as nearly as possible the same conditions. To illustrate this, let us assume we had to analyse a series of alkaline carbonates by means of a standard hydrochloric acid. Ppn. of a known volume of the reagent by nitrate of silver, and weighing the pp. of AgCl (or the corresponding process of titration) would no doubt give the most exact result for the number of mgms. of HCl contained in 1 c.c. of the reagent. Yet it is better in our case to standardise the

---

cases like that referred to. Instead of filtering off the CuO pp., we allow the mixture to cool, dilute to a known volume, V c.c., filter through a *dry* filter, and measure off a known aliquot part of the filtrate, v c.c., for the titration. If V is sufficiently large, the volume of the CuO need not be taken into account; supposing for instance V = 500 c.c. and the pp. of CuO amounts to 1 gm., the error introduced by neglecting its volume amounts certainly to no more than about 0·5 c.c., or 0·001 of the whole.

acid by means of a known weight of pure carbonate of soda, although this method, as one for the determination of HCl, could not for a moment be compared with either silver process in point of inherent precision.

In now passing from generalities to the consideration of individual methods, we shall confine ourselves in the main to those methods which are applicable to whole classes of bodies. Under the head of each we shall briefly state what applies to it as a *general* method. For special applications of these methods, as for special methods generally, also in regard to technicalities, we must refer to the special handbooks.[1]

I. *Methods based on double decompositions.*

Theoretically these processes are founded on equations of the form

$$\underset{\text{A},}{ax} + \underset{\text{B},}{by} = \underset{\text{C},}{ab} + \underset{\text{D},}{xy}$$

where a and b are the constant radicles characteristic of the process. Here we have to distinguish between two cases:—I. C *and* D *remain dissolved.* Only a very few processes fall into this group. As an example, we may quote Liebig's process for the titration of NCH by neutral nitrate of silver. Large excess of potash is added, the liquid is diluted largely, and, after addition of a little NaCl as indicator, standard $AgNO_3$ (neutral) is dropped in until the cloud of AgCl becomes permanent, showing that the reaction $2KNC + AgNO_3 = KAg(NC)_2 + KNO_3$, has been just completed. II. *The characteristic product* $C = ab$ *comes down as a pp.* Of these numerous processes, only those need now be noticed in which, on account of the absence of an *end-reaction*, and of a suitable indicator, the end-point cannot be recognised otherwise than by proving quite directly that the ppn. has just reached its end. If the pp. settles readily, this can be done with comparative ease—in an obvious manner; but easily settling pps. are exceptional. It is more generally practicable to get the pp. to settle so far that it is possible to draw off a few drops of the clear top-stratum, and to examine them on a watch-glass by addition of a drop of B, or of a solution of A, or of any delicate reagent for A or B. If this method does not work, the only course left is, from time to time, to take out a little of the mixture, filter it through paper, and examine the filtrate. One way of doing this is to put a drop of the fluid on a small double filter-paper, and to examine the lower filter by means of some reagent which strikes an intense colour with A or B as the case may be. But such colour-tests are not always available, so that ordinary filtration must generally be resorted to. Each such filtration of course means a loss of a, and consequently ought to be done with a measured aliquot part of the whole, to enable one to allow for the loss by calculation. This, however, is apt to lead to errors; in practice it is better in the first trial to neglect the error, and in a second and third practically to avoid it by filtering only a few times near the end of the process, when the amount of unppd. A has become very small. In any case it is convenient to have a standard solution of some reagent, ax', by means of which to retrace one's steps if an excess of pptnt. has been added. This auxiliary solution is best adjusted so that it pps. exactly its own volume of D. The method of procedure then assumes this form:—We add B, finally in small instalments of, say, 4 c.c. each, until by the last instalment the end-point has been over-stepped; we then go back with A-solution, adding it in instalments of 2 c.c., until *this* reagent is in excess; we then again apply B in portions of 1 c.c., &c., until we come to know that, say, v c.c. of B is too little, while v + 0·2 c.c. is an excess; or that (v + 0·1 c.c.) ± 0·1 c.c. may be adopted as the final result.

Of the vast number of *precipitation-analyses* which have been invented, only those founded upon mutual decomposition of solutions of Silver salts and haloids occupy the rank of precise methods. If (dissolved) chloride and (dissolved) silver-salt meet in a neutral or acid solution the whole of the potential chloride of silver is formed, and comes down as a pp. as demanded by the equation,

$$RCl + AgNO_3 = AgCl + RNO_3.$$

Upon this, and the fact that the AgCl (if sufficiently abundant) readily unites on shaking into a quickly settling pp., Gay-Lussac long ago founded his famous process for the determination of silver by standard NaCl solution, which process is directly translatable into an equally exact process for the determination of chloride by standard silver. The equation, however, is not an absolutely correct theory of either process. Gay-Lussac observed that if the silver nitrate and the sodium chloride are exactly balanced against each other, the clarified mixture gives a distinct cloud with either reagent. Hence to exactly complete the ppn. of (say) $AgNO_3$ mgms. by salt, we must add, not NaCl, but a trifle more, call it $(1 + \alpha)$NaCl mgms. And similarly, the complete ppn. of NaCl mgms. demands $(1 + \beta)AgNO_3$ mgms. The exact values of α and β vary with the experimental conditions, and are not susceptible of separate determination. Hence to determine an unknown weight, $x \times$ Ag mgms. of silver (if we do not care to neglect the correcting factors), all we can do is: (1) to add standard chloride solution—at last in very small instalments, corresponding to say 0·02 mgms. of silver each—until the ppn. is exactly completed by, say, $n \times$ RCl mgms. as calculated from the strength of the solution, and the quantity used. We then (2) titrate back with (very dilute) standard silver until the last drop no longer gives a cloud of AgCl, which will take, say, $\epsilon \times$ Ag mgms. The mixture now is (practically) in the same condition as if no silver had been added but the chloride diminished by $\epsilon \times$ RCl mgms.

Obviously the truth lies between $x = n$ and $x = n - \epsilon$, and we may say $x = (n - \frac{\epsilon}{2}) \pm \frac{\epsilon}{2}$.

Or, to put it somewhat differently; we have

$$2x = 2n + (\beta - \alpha)n - \epsilon \quad . \quad . \quad . \quad . \quad . \quad \text{I.}$$

$$\text{and } 0 = n(\beta + \alpha) - \epsilon \,. \quad . \quad . \quad . \quad . \quad . \quad \text{II.}$$

If we knew that $\alpha = \beta$, we should have $x = n - \frac{\epsilon}{2}$ exactly.

---

[1] Mohr's *Lehrbuch der chemische-analytischen Titrirmethode*; 2, Fleischer, *Die Titrirmethode*; 3, Fleischer, *Die Titrirmethode*, English edition *Volumetric Analysis*, translated by M. M. Pattison Muir; 4, Sutton, *Volumetric Analysis*; 5, Fresenius, *Quantitative Analysis*.

According to Mulder, if the silver, calculated as metal, amounts to about 1 gram, and is diffused throughout some 120 to 150 c.c. of mixture $(\alpha+\beta)=0{\cdot}001$, about.[1] The explanation given in regard to chlorides holds substantially for bromides, iodides, cyanides (NCR); sulphocyanides (perhaps also for cobaltocyanides, and some other metallo-cyanides); in the case of bromides, however, the numbers α and β are practically equal to *nil* (Stas), AgBr being even more insoluble in HNO_3 and KNO_3 &c. solutions than AgCl is; hence we may *surmise* that the $(\alpha+\beta)$ for iodide is still nearer to nothing. The cases of NC.R and NCS.R have not been investigated in this sense. Presumably the $(\alpha+\beta)$ for cyanide is greater than, and that for (NCS)R is about equal to, the value for chlorides.

Given (let us say) an alloy for which the percentage of silver is approximately known (say to ±0·5 p.c.); the exact determination of the noble metal by titration with standard chloride (*e.g.* NaCl) solution offers no difficulty; but with an alloy &c. of utterly unknown composition the process even in practised hands is apt to be tedious. Practical assayers, indeed, never apply Gay-Lussac's method without having first made a preliminary assay by the old method of cupellation. Volhard, some years ago, invented a modification of Gay-Lussac's method, which, with a small number of samples at least, is quicker even than cupellation, and, in all cases, is more accurate. He dissolves a known weight (equal to presumably 0·5 grm. of silver) in nitric acid, dilutes moderately, *boils off all the* N_2O_3, adds 5 c.c. of saturated iron-alum solution, and then drops in standard sulphocyanide of potassium (or ammonium) until the red colour of $Fe(NCS)_3$ becomes permanent. (The large quantity of indicator prescribed is necessary, or else the end-reaction lacks delicacy.) For the determination of chlorine (given as RCl), Volhard pps. the chlorine first by an excess of standard silver, he then adds iron-alum, and (without removing the AgCl[2]) titrates back with KNCSAq until the end-point is reached.

A very handy (but less exact and less widely applicable) method, introduced by Mohr, may here be referred to. He brings the chloride into neutral or very feebly alkaline solution, and, after adding a few drops of yellow chromate of potassium, titrates with neutral silver nitrate until the red colour of the Ag_2CrO_4 becomes permanent. The method, if used as an empirical one, gives very good results.

STANDARD SUBSTANCES AND SOLUTIONS.

1. *Standard silver.*—Best prepared by Stas's[3] process (precipitation of a cupriferous ammoniacal solution of nitrate by added alkaline ammonium sulphite). The ppd. metal, after having been washed, first with ammonia in the presence of air, then with water, is heated to redness, when it becomes semi-compact. It is then broken up in a mortar into granules, again heated, and preserved in this form. There is no need of going to the trouble of fusing the metal, provided it is proved to be free from every trace of chloride.

2. *Standard chloride.*—Pure chloride of sodium is universally recommended. The writer prefers pure KCl prepared by strongly heating re-crystallised perchlorate. The perchlorate is deoxygenated as far as convenient in a platinum basin, and then fully by fusion in a platinum crucible. The fused salt is quite neutral; yet for *very* precise work it is perhaps better to dissolve the fused salt in water, add hydrochloric acid, evaporate to dryness (in platinum), and keep the residue at a temperature just short of the fusing point until the weight is constant.

3. *Standard solutions of* 1 *and* 2.—Both can be standardised synthetically, on the basis of Stas' atomic weights; for general purposes $\frac{Ag}{10}$ and $\frac{KCl}{10}$ grms. per litre are convenient strengths. For exact work the solutions are combined with centinormal solutions, containing $\frac{Ag}{100}$ and $\frac{KCl}{100}$ grms. per litre.

4. *Pure bromide of potassium*, and standard solution ($\frac{KBr}{10}$ grms. per litre) of the same for *very* precise determinations of silver. Regarding the preparation of the pure salt, see Stas's *Memoir.*

5. *Standard sulphocyanide.*—About $\frac{1}{10}$ $NCS.NH_4$ grms. of the pure (chlorine-free) ammonium salt is dissolved to 1 litre, and the exact strength is determined empirically by means of a known weight of silver dissolved as nitrate.

II. *Methods based on saturations*, that is, reactions of the type

$$XH + ROH = HOH + XR;$$

regarding these, we have little to add to what was given under *Theory of Titration* (*q.v.*). For $XH = NO_3H, \frac{1}{2}SO_4H_2, ClH, HClO_4$, and other strong acids (including oxalic and formic) on the one hand, and R = K,Na, generally, and for $R = \frac{1}{2}$ (Ba, Sr, Ca) as long as no insoluble salt is produced, on the other, the equation is a strictly correct theory of the process. For phosphoric acid, HX must be taken as representing $\frac{1}{2}H_2(HPO_4)$, RHO being an alkali, but even then the results are not very constant. For weaker acids, such as acetic, butyric, &c., the method is purely empirical. An approximation to a standard acetic acid is obtained by measuring off a known volume of standard sulphuric acid, and adding say two equivalents of perfectly neutral acetate of soda. In determinations of ammonia it is as well not to assume that NH_4OH is an absolutely exact equivalent for KOH or NaOH.

STANDARD SUBSTANCES AND SOLUTIONS.

1. *Pure carbonate of sodium*, as a general standard alkali. Prepared from pure bicarbonate (recrystallised as such) by strongly heating in platinum. The salt must not be fused for de-

---

[1] Our impression is that Mulder over-estimated the value.

[2] The writer finds that high precision can be reached only by *removing* the AgCl pp. before titrating back with KNCS. (See Dittmar's *Report on the Composition of Ocean Water*, p. 4. ['Challenger' Memoirs.] Also his *Exercises in Quantitative Analysis*, section on *Sea-water.*)

[3] *Recherches sur les rapports réciproques des poids atomiques* (Bruxelles, 1860); and *Nouvelles Recherches*, &c. (Bruxelles, 1865), or German translation of both works Aronstein (Leipzig, 1867).

hydration, or else it loses carbonic acid. To obtain a really pure, and especially a potash-free, salt, the best method is to add pure oxalic acid to a decided excess of solution of the purest obtainable carbonate of soda, to collect the pp. of $C_2O_4Na_2$ formed, to wash it by displacement and to reduce it to Na_2CO_3 by heating strongly (W. D.).

2. *Oxalic acid*, $C_2H_2O_4 + 2H_2O$, recommended by Mohr as a general standard acid. See that the preparation is free from fixed matter (*e.g.* potassium salts). If not, recrystallise it from hot 10 p.c. HCl, repeatedly, and lastly from water (Stolba). The carefully air-dried crystals have the correct composition. We prefer a hydrochloric acid, standardised by silver, for general purposes.

3. *Solution of standard acid.*—Sulphuric works best for alkalis; hydrochloric is preferable for general purposes. The latter may be standardised by means of silver; either acid by means of a known weight of carbonate of soda,[1] with standard alkali as an auxiliary reagent. Thorpe recommends for the standardisation of SO_4H_2, to add a known (excessive) weight of Na_2CO_3, to evaporate to dryness, heat, and weigh the residue. As every Na_2CO_3 grms. in passing into Na_2SO_4, gains $(SO_4 - CO_3)$ grms., every 1 grm. of gain of weight corresponds to $\frac{SO_3}{SO_4 - CO_3}$ grms. of sulphuric anhydride. (I have tested this method, and found it to give very good results.—W. D.)

4. *Solution of standard alkali.*—Caustic potash or caustic soda for general purposes. The reagent must be as free as possible from carbonate. The preparation known as *potash purified by alcohol* almost fulfils this condition. The best method is to causticise an almost carbonic acid free (dilute) ley with a *slight* excess of baryta in a nickel vessel; allow to settle, and preserve in a bottle provided with a protection-tube filled with granulated soda-lime, or baryta, $Ba(OH)_2$. The trace of dissolved BaO disposes of traces of CO_2 that find their way into the reagent while being preserved. $\frac{1}{5}$ROH grms. per litre is a convenient strength. It is standardised empirically against measured standard acid.

5. *Standard baryta water* containing about $\frac{1}{8}Ba(OH)_2$ grms. per litre is used for special purposes, *e.g.* determination of free or liberated CO_2. A stronger reagent is apt to deposit crystals in cold weather. It is standardised empirically against standard hydrochloric acid. In the absence of sulphates, baryta water is the best standard alkali for all purposes.

III. *Methods based upon processes of oxidation and reduction.*

(As illustrated in *Theory of Titration*, by reference to Bunsen's methods.)

I. Iodine (solution of I in KI) as oxidant is available for the measurement of the following reducers:—

1. *Dissolved sulphurous acid* acts normally under the conditions stated under *Theory of Titration*.

2. *Dissolved alkali thiosulphate* (in the absence of excess of alkali; even carbonate is not permissible) acts normally at any state of concentration which one could reasonably employ. In the *presence of acid* the reaction takes its normal course only if the solution is sufficiently diluted, and the $H_2S_2O_3$ has no time to decompose spontaneously. In practice, however, this spontaneous decomposition is out of court, because, in all cases in which free acid is present, it forms part of the iodine solution, and the thiosulphate plays the part of reagent, so that the $S_2O_3H_2$ liberated passes at once into $S_4O_6H_2$, which is sufficiently stable. Free sulphuric acid in any quantity must be avoided (*v. supra*); free hydrochloric acid in moderate quantity does no harm, if the given iodine solution is diluted to about $\frac{1}{4}$–$\frac{1}{5}$ of the strength of the customary standard solution.

3. *Alkaline arsenite.* The reaction proceeds (not as promptly as those of 1 and 2, but) in a fair degree normally, provided there is enough of *pure* carbonate or bicarbonate of alkali to keep up an alkaline reaction to the end (Mohr). The best auxiliary alkali to add is sesqui-carbonate of ammonia; it does not decolourise iodide of starch, to anything like the (slight) extent to which Na_2CO_3 does (Mohr; later communication).

4. *Alkaline antimonite*, or rather Sb_2O_3 given as tartar emetic or in similar forms, is oxidised by iodine just as As_2O_3 is (Mohr). Results fair.

5. *Stannous chloride.* The execution of the process $(SnCl_2 + 2HCl + I_2 = 2HI + SnCl_4)$ offers no difficulty, and added starch solution defines the end-point sharply; but the results are very variable and inexact.

6. *Sulphuretted hydrogen* H_2S (in *much* air-free water) with iodine reacts substantially thus:—$I_2 + H_2S = 2HI + S$. Results are only approximate, yet the method is of some value for determining *small* quantities of H_2S in much water.

II. Iodine in combination with reducers for general purposes.

Only the combinations I_2 and H_2SO_3, and I_2 and $Na_2S_2O_3$ are used now-a-days. Discussion anticipated in section on *Theory of Titration*.

III. Permanganate of potassium, as an oxidant,

measures the following reducers directly, and in all cases the intense colour of the reagent marks the end-point with great sharpness.

1. *Ferrosum.* A dilute, strongly acid, solution of ferrous sulphate, when titrated with solution of permanganate, is promptly oxidised into ferric salt with formation of MnO-salt from the reagent (Marguerite).

Conditions of success:—*a*, large dilution; 1 litre of solution should contain at most 1 gram of metallic iron; *b*, a sufficiency of free sulphuric acid, more than the equation demands, or else MnO_2 may separate out as a pp.; *c*, absence of hydrochloric acid (and chlorides generally), or else part of the reagent is reduced by it with formation of Cl_2. According to Zimmerman, however, this by-reaction can be prevented by addition of manganous sulphate to the ferrosum solution. 4 grams of the salt $MnSO_4 + 4H_2O$, suffice per 60 c.c. of 20 p.c. HCl used for dissolving the respective iron compound.

---

[1] Ppn. with $BaCl_2$ and weighing the $BaSO_4$ is not a very exact method for the standardisation of a sulphuric acid.

Iron given as ferric salt may be reduced to ferrous salt, by (1) treatment with H_2S; (2) prolonged treatment in a warm solution with Na_2SO_3 and HCl (works better with chloride than with sulphate solution)—in either case the excess of reducer must of course be expelled by ebullition —(3) zinc and acid; handy, but not so trustworthy as (1) or (2).

2. *Oxalic acid.* A strongly sulphuric solution of this acid is oxidised by the reagent into carbon dioxide and water (Hempel). The reaction at first proceeds very sluggishly, but then more and more promptly, as the quantity of $MnSO_4$ produced increases. Hence the expediency of adding $MnSO_4$ from the first (De Koninck). Whether hydrochloric acid interferes with this reaction as with the preceding one (whether, for instance, it is permissible to dissolve oxalate of lime given for the determination of its oxalic acid in hydrochloric acid before titrating) has not yet been determined.

3. *Arsenious acid.* Arsenious acid in strongly hydrochloric solutions is oxidised by permanganate into arsenic acid, but part of the manganese separates out as MnO_2 (Kessler).

4. *Antimonious acid* as $SbCl_3$, in a solution which contains not less than 1-2 volumes of hydrochloric acid for 5 of water, is readily and completely oxidised into Sb_2O_5. The reaction is available quantitatively. [(3) and (4), Kessler, *J.* 1863. 683)].

5. *Sulphurous acid* is readily oxidised into sulphuric; not investigated quantitatively, as far as we know.

6. *Peroxide of hydrogen.* In the presence of water and dilute sulphuric acid, the mutual reduction

$$5H_2O.O + Mn_2O_7 = 5H_2O + 2MnO + 5O_2$$

proceeds normally and promptly.

7. *Nitrous acid* (liberated from nitrite by H_2SO_4 in *very* dilute solutions) is oxidised by permanganate to nitric acid. Results, under certain conditions, fair.

8. *Cu_2O* (ppd.) dissolved in acid iron alum, is oxidised readily, and fairly normally, to 2CuO.

IV. Combined application of permanganate and reducing agents.

A. Ferrosum as reducer.

The higher oxides of manganese, when digested with HCl or dilute H_2SO_4 and excess of ferrous salt, are readily dissolved as MnO-salt, with formation of a quantity of ferricum proportional to the loosely held oxygen in the peroxide. In the absence of atmospheric oxygen, *i.e.* in an atmosphere of CO_2, the reaction takes its normal course, and becomes available for an obvious remainder-method for the determination of such oxygen. No doubt available for other peroxides.

Upon the ready action of *alkaline* permanganate on the sulphides, sulphites, thiosulphates, iodides, arsenites, formates, of K or Na, with formation of sulphate, iodate, arsenate, carbonate, respectively (and hydrated binoxide of manganese), Péan de St. Gilles (*A. Ch.* [3] 55, 374), has founded a general method for the determination of the respective acids by means of a standard solution of permanganate, and an auxiliary solution of ferrous sulphate. After having carried out the required oxidation by means of excess of permanganate and a sufficiency of caustic potash, the mixture is acidified, the MnO_2 and surplus Mn_2O_7 reduced by addition of, first, acid, and then excess of ferrous solution, and finally the surplus ferrosum is titrated by addition of more of the permanganate solution.

B. Oxalic Acid as reducer.

Any higher oxide of manganese, $MnO.O_x$, when digested with excess of oxalic acid and sulphuric acid, is dissolved as $MnSO_4$, with formation of CO_2 from the reagent. The oxalic acid is used as a standard solution, and what remains over after the oxidation is determined volumetrically by permanganate. (Calcium oxalate may separate out as a pp.)

V. Chromic acid (in practice a solution of $K_2Cr_2O_7$) as oxidant

is available for the direct titration of the following reducers:

1. *Ferrosum.* Ferrous sulphate or chloride, in the presence of free acid, is readily and completely oxidised by added bichromate solution. The latter may be standardised synthetically (or analytically by means of a known weight of dissolved ferrosum). The end point is recognised by means of ferricyanide as a *drop-test.* The results are in exact accordance with the chemical equation, even in the case of hydrochloric solutions (Penny; Schabus). An unknown weight of CrO_3 can be determined with equal exactitude by adding a known excessive weight of ferrosum (as sulphate) to the previously acidified solution, and titrating back with bichromate solution.

The combination *$K_2Cr_2O_7$ and ferrous salt* is equivalent to that of $Mn_2O_7K_2O$ and the same reducer. It is available likewise for the determination of As_2O_3 and Sb_2O_3 in strongly hydrochloric solutions. The solution is mixed with a (measured) excess of bichromate solution, and the mixture allowed to stand to give the oxidation time for completion; a known excessive quantity of ferrosum is then added, and its excess is titrated by means of bichromate (Kessler).

2. *Sulphurous acid, Sulphuretted hydrogen, Stannous chloride,* in mineral acid solutions, are readily oxidised by CrO_3 into SO_3, $S + H_2O$, $SnCl_4$, respectively, and in all cases iodide of potassium and starch afford a sensitive indicator of excess of oxidant, which sharply defines the apparent end-point of the process. But, unfortunately, the corresponding ratio of the reagents in no case coincides with that demanded by the respective equations, nor is it even constant in itself. It varies according to the degree of dilution, the proportion of free acid, the quantity of absorbed air in the reagents, &c., in a manner which defies all calculation (Kessler, Mohr, Casselman).

VI. Ferric chloride, in combination with Stannous chloride.

The oxidation of an acid solution of $SnCl_2$ by added ferric chloride proceeds very readily when the liquid is hot, and in fair accordance with the equation:

$$SnCl_2 + Fe_2Cl_6 = SnCl_4 + 2FeCl_2;$$

but the dissolved air of the reagents is drawn into the oxidation, and the results are consequently irregular. If however (according to Fresenius) we start with a hot, strongly acid, solution of ferric chloride, and at a nearly boiling temperature drop in stannous chloride, the process proceeds exactly as described by the equation, and the disappearance of the last trace of the yellow colour of the ferric salt defines the end-point very sharply. In case of doubt, add a slight excess of $SnCl_2$, *allow to cool*, add starch, and titrate with iodine solution to determine the excess of $SnCl_2$, and allow for it. According to the writer's experience the whole of these operations must be done in an atmosphere of CO_2, else the results are not exact. Fresenius utilises the process for the determination of nitric acid. The nitrate to be analysed is allowed to react with an excess of ferrous sulphate, strongly *acidified by HCl*, in an atmosphere of H or CO_2 first cold, then hot; the NO is boiled off, and the ferricum produced is determined by means of standard $SnCl_2$. The ferricum present as an impurity in the ferrous salt is determined by a blank experiment, and is allowed for: 6 × Fe of ferricum produced, indicate $1 \times N_2O_5$ of nitric anhydride.

Standard Substances and Solutions, for the Processes of Oxidation referred to.

1. *Pure iodine* is best made by Stas's method. Ordinary iodine is dissolved in the minimum of a highly concentrated solution of iodide of potassium, and re-ppd. as far as possible by dilution with water. The pp. is washed, dried first on a porous tile, then over CaN_2O_6. The dry product is distilled (or the small quantity needed for an experiment sublimed *ex tempore* between watch-glasses), the first instalments of vapour being rejected on account of possible contamination with water. From such iodine

2. *A standard iodine solution* might easily be made by exact synthesis. But it is more economical and less troublesome to prepare this solution by approximate synthesis from ordinary good iodine (5 grams of I_2 dissolved in 10 grams of IK and 10-20 c.c. of water in a mortar, and diluted to 1 litre, gives a solution of convenient strength); and to determine the exact strength by comparison with a known weight of pure iodine, by means of a thiosulphate solution of arbitrary strength. Supposing p mgms. of pure iodine weighed directly, and dissolved in IK solution, require t_0 c.c. of thiosulphate for their decolourisation, while n c.c. of the iodine-solution require t c.c.; then 1 c.c. of thiosulphate is equivalent on the one hand to $\frac{p}{t_0}$ mgms. of iodine, and on the other to $\frac{n}{t}$ c.c. of iodine-solution. Hence 1 c.c. of the latter contains $\left(\frac{pt}{t_0 n \times 127}\right) \times I(=127)$ mgms. of pure iodine.

3. *Thiosulphate solution.* — Made by dissolving 10 grms. of the pure salt, $Na_2S_2O_3.5H_2O$, in water, to 1 litre. It decolourises about its own volume of the above iodine-solution. The strength is determined empirically by means of the latter.

4. *Arsenious acid.*—Pure As_2O_3 is to be had in commerce; but the best qualities even are liable to be contaminated with Sb_2O_3. powder is not hygroscopic.

5. *Arsenite solution.*—4·95 grms. = $\frac{As_2O_3}{40}$ powdered As_2O_3 along with 11 grms. of p Na_2CO_3 (= 30 grms. of crystals, $Na_2CO_3 + 10H$ are dissolved in a slanting litre flask in wat over a water-bath; after cooling, the liquid diluted to 1 litre. 1 c.c. = 0·1 × 'I,' 'Cl,' d mgms. [This solution, as a reagent, may ser for the direct titration of dissolved hyp chlorite — $2RClO + As_2O_3 = 2RCl + As_2O_5$. T end-point is recognised by means of iodide potassium and starch paper; a drop of t mixture when placed on the paper produces blue stain only as long as the RClO is in exces (Pénot)].

6. *Standard ferrosum.*—Fine pianoforte wi is sure not to contain more than 0·4 p.c. c impurities, and consequently may be assume to represent 0·998 ± 0·002 times its weight o real iron. A known weight is dissolved in HC or dilute H_2SO_4, in the absence of air, &c. Mor convenient is

Ferrous sulphate.—$FeSO_4.7H_2O$, ppd. from a pure, hot, concentrated, acid solution, by alcohol. The ppd. salt is washed with alcohol, dried on bibulous paper, and finally by exposure to the 'dry' air of a room. The dried salt is sifted to remove lumps, again exposed to the air for a while, and bottled up for use. The exact percentage of iron is determined by strongly heating a known weight in a platinum crucible—at the end in the presence of air—until the weight is constant, and weighing the Fe_2O_3. This old preparation of Otto, according to the writer's experience, has a higher degree of stability in air than Mohr's salt $(Fe(NH_4)_2S_2O_8.6H_2O)$.

7. *Standard oxalic acid.*—The crystallised, normal, ammonium salt is the best standard oxalate for processes in which it serves as a reducing agent. If air-dry, it has exactly the composition $C_2O_4(NH_4)_2 + H_2O = 142$.

8. *Standard permanganate of potassium.*—An almost pure salt is to be had in commerce. Yet it is not pure enough to serve as a standard substance in itself. A convenient solution is obtained by dissolving a little more than 3·16 grms. (= 5·6 grms. of ferrosum) in water, in a mortar, and diluting to 1 litre. The solution is standardised by means of a known weight of ferrosum or oxalate of ammonium, according to the object which it is meant to serve.

9. *Bichromate of potassium.*—$K_2Cr_2O_7$. The pure salt is not difficult to obtain; but it is not easy to prove that it contains exactly $2CrO_3$ for $1K_2O$. Besides, the uncertainty of the atomic weight of chromium is a difficulty. To prepare the salt for use, it is powdered and dehydrated by keeping it near its fusing-point for a time in a platinum basin. It is then fused at the lowest temperature, and allowed to solidify, when it breaks up spontaneously into small granular fragments, and thus assumes a convenient form for weighing.

10. *Standard solution of bichromate of potassium.*—A convenient concentration is $\frac{K_2Cr_2O_7}{60} =$ 4·92 gms. per litre. It may be standardised

synthetically; but for the reasons stated it is on the whole preferable to standardise the solution analytically by means of a known weight of dissolved ferrosum.

11. *Standard ferric chloride.*—Pure ferric oxide is prepared by strongly heating ferrous oxalate. It is dissolved, by prolonged digestion, in fuming HCl, and the solution is diluted to the right volume. $\frac{Fe_2O_3}{20}=8$ grms. per litre is a convenient strength.

12. *Stannous chloride* (for No. 11). Pure granulated tin (approximately weighed) is boiled with pure HCl until a sufficiency of the metal is dissolved. The residual metal is weighed, to ascertain how much has passed into solution. For every 3 grms. of dissolved tin, the solution is diluted – with air-free water – to 1 litre. The solution decolorises about ½ its volume of the iron solution, which latter serves for its standardisation. This solution is so prone to oxidise in the air that it must be restandardised expressly for each analysis. W. D.

ANALYSIS, ORGANIC. Ultimate organic analysis is the determination of the elements present in an organic substance. Proximate organic analysis is the determination of the compounds present in a mixture, or of the radicles present in a compound.

Ultimate Analysis.

Qualitative.

Carbon. If a substance blackens when it is heated either alone or with sulphuric acid it probably contains carbon, in which case the black residue may be burnt away by heating to redness in air. A substance that does not blacken may nevertheless contain carbon. A more general method of detecting carbon is first to warm the substance gently with dilute sulphuric acid, in order to expel CO_2 that may be present as carbonate, and then to add several volumes of strong H_2SO_4 and some $K_2Cr_2O_7$; when the mixture is heated any organic substance will be oxidised, and the escaping CO_2 will give a pp. with lime-water.

Hydrogen. The substance is mixed in a tube with dry CuO or $PbCrO_4$ and heated to redness; water comes off and condenses in a cold tube. Very small quantities of water may be detected by passing the gases through a glass tube lined with P_2O_5, which will deliquesce. In these experiments carbon may be detected by passing the escaping gases into lime-water.

Nitrogen. The substance is heated with soda-lime and the nitrogen may then be given off as NH_3 and detected by its smell, action on red litmus, or fumes with HCl. The soda-lime must be strongly heated before use, until it no longer gives off NH_3. This test will not succeed with compounds rich in oxygen. A more delicate test consists in heating the substance with potassium in a test-tube drawn out to a point. After deflagration, the mass is dissolved in water and examined for cyanide (Lassaigne, *A.* 48, 367). This test is not applicable to diazo-compounds (Graebe, *B.* 17, 1178).

Chlorine. The chlorine is eliminated in the form of a chloride, the presence of which is detected by $AgNO_3$. The conversion into chloride can be effected: (*a*) by boiling with fuming HNO_3; in the case of volatile substances, the operation must be performed in a sealed tube: (*b*) by boiling with alcoholic potash: (*c*) by mixing with quicklime and heating to redness: (*d*) by heating with H_2SO_4 and MnO_2.

Bromine and *iodine* may be detected by the same methods.

Halogens may also be detected by fixing a lump of CuO to a platinum wire, dipping it into the substance, and heating first in the inner and then in the outer part of a Bunsen flame: a green colour indicates halogens (Beilstein, *B.* 5, 620).

Sulphur is detected by strongly heating the substance with a mixture of sodic carbonate and sodic nitrate, or sodic carbonate and potassic chlorate; and testing the product for sulphate. Or the substance may be fused with sodium free from sulphur in a test-tube, and the product examined for sulphide (Schönn, *Fr.* 8, 52, 399). Some compounds, such as albumen, give a black pp. of PbS when boiled with a solution of PbO in NaOHAq. Boiling $HgCl_2$ or ammoniacal $AgNO_3$ often give a black pp. of metallic sulphide.

Phosphorus may be detected by fusing with Na_2CO_3 mixed with $NaNO_3$, and examining the product for phosphate. Or the carbonised substance may be heated with magnesium powder; the product, containing magnesium phosphide, is luminous in the dark, and when moistened with water will give off PH_3 (Schönn, *Fr.* 8, 55).

Quantitative.

Substances containing no elements beside carbon, hydrogen, and oxygen.

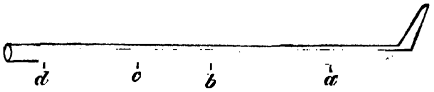
The substances are subjected to *Combustion* as proposed by Liebig (*P.* 21, 1), hydrogen being weighed as H_2O and carbon as CO_2. The operation is performed in a closed or in an open tube.

Closed tube, combustion.

A tube of hard glass (diameter ·5 inch) is drawn out as represented, the length being about 18 inches. It is thoroughly cleaned by washing with fuming HNO_3, water, alcohol, and ether; and is then dried. Coarsely powdered oxide of copper, which has been prepared by oxidising the metal, not by strongly heating the nitrate, and has been dried at a red heat, is poured in as far as *a*; a mixture of the weighed substance with finely powdered dry CuO is then poured in, it fills up the space from *a* to *b*; the vessel (mortar or glass tube) in which the mixture has been effected is then rinsed with more finely divided CuO, and these rinsings are poured into the tube and take up the space *b* to *c*; finally some coarse CuO is poured in, taking the space *c* to *d*. The tube is then gently tapped to ensure free passage for gas from end to end. A tube containing $CaCl_2$ is fixed by means of a cork to the open end of the combustion tube, and a bulb-apparatus (Liebig's or Geissler's) containing caustic potash (1 pt. KOH to 2 pts. H_2O) is attached to this, and in accurate experiments a drying tube containing $CaCl_2$ or solid KOH is placed beyond the potash-bulbs.

The oxide of copper at *d* is first heated to redness, and then the tube is heated at the other end; the gas-burners of the furnace are then

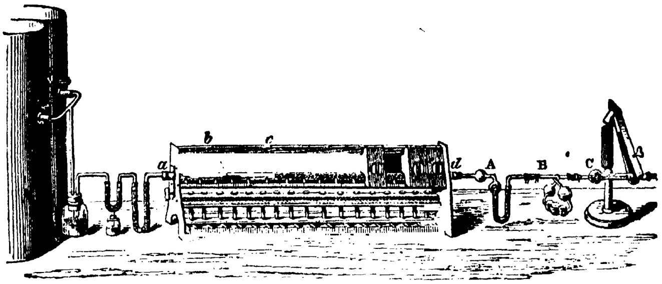
gradually turned on, at either end, so that a regular stream of bubbles passes into the potash bulbs. When the entire tube has reached a dull red heat, the potash solution will begin to be sucked back, owing to absorption of CO_2; at this moment the point of the tube is broken off, and air is sucked through the entire apparatus in order that the gases still contained in the tube may be drawn into the weighed bulbs; in this operation a long glass tube, open at both ends, may be placed over the broken point of the tube to prevent furnace gases being sucked in. The calcium chloride tube and potash bulbs are weighed when cool: $\frac{1}{9}$ of the increase of weight of the former is hydrogen, $\frac{3}{11}$ of the increase of weight of the latter is carbon.



Open tube, combustion.

It is in every way better to make the combustion in an 'open tube,' that is a tube through which oxygen is continually passing.

The greater part of such a tube is filled with oxide of copper, *c d*; this is followed by an open space of about 2 inches; then comes a porcelain or platinum boat, *b*, containing the weighed substance; beyond (between *b* and *a*) it is advisable to have a spiral of oxidised copper. The boat and its contents are not inserted until the whole tube has been red hot for some time, during which a current of dry oxygen, free from carbonic acid, has been passing through it; it is of course necessary to allow the end *a c* of the tube to cool down before inserting the substance, otherwise this would be volatilised too rapidly. While the tube is cooling, the calcium chloride tube A, potash bulbs B, and the drying tube C are attached. The tube, which is still red-hot from *c* to *d*, is now heated at *a* and the burners are lighted one after another until the whole tube is red hot. A slow current of oxygen is passed in at *a* during the combustion. The combustion is continued until oxygen escaping from C will rekindle a glowing match. Before weighing, the oxygen in the tubes A, C, but especially B, must be displaced by air; in a properly conducted experiment C will not gain more than ·01 g., a greater increase indicates spurting of the potash due to a too rapid current of gas. At the end of one experiment the tube is quite ready for a second.



Liquids of high boiling-point are analysed in the same way as solids, except that they are weighed in short open tubes; volatile liquids such as ether are best put into a bulb or V-tube, which is inserted between the oxygen apparatus and the combustion tube; the proportion between oxygen and vapour of the substance depends upon the temperature of the bulb-tube and should be so regulated that the oxygen should be always in considerable excess, otherwise an explosion might occur.

The potash-bulbs may be replaced by a U-tube containing soda-lime; in this case the escaping gas must be allowed to bubble through H_2SO_4 in order that the rate at which it is coming off may be noted.

Minute quantities of carbonic acid are absorbed by CuO and even by $PbCrO_4$ and retained at a red heat. Hence in the determination of minute quantities of carbon (as in the residue from drinking water) these substances should be previously ignited in a current of air (Dittmar a. Robinson, *C. N.* 36, 26).

Minute quantities of carbon may also be estimated by burning in an open combustion tube in a current of oxygen, in the usual way, and absorbing the CO_2 in baryta water. The $BaCO_3$ is filtered off, converted into sulphate and weighed (Dupré a. Hake, *C. J.* 35, 159). Other methods are described below.

Combustion with Chromic Acid.

Carbon may be determined by heating the substance with CrO_3 and H_2SO_4 and measuring the mixture of CO and CO_2 given off (Cross a. Bevan, *C. N.* 52, 207).

Substances containing Nitrogen.

Determination of Carbon and Hydrogen.

If the substance contains nitrogen, **nitrous fumes might be evolved, and those would be absorbed in the weighed tubes. To prevent this, a layer of metallic copper is put in the front of the tube, near *d*, and kept red-hot: it reduces oxides of nitrogen to nitrogen. This copper is best** obtained by heating a roll of wire gauze in a Bunsen flame, and reducing the oxidised surface in a current of hydrogen; it should then be allowed to cool in a current of CO_2, as it would absorb hydrogen if left to cool in that gas. The copper spiral may also be reduced by heating it in the mixture of CO and CO_2 obtained by warming oxalic acid with H_2SO_4 (C. E. Groves, *C. J.* 37, 505).

Binoxide of manganese mixed with potassic chromate may be used instead of a reduced copper spiral in combustion of nitrogenous substances. The mixture is made by stirring precipitated binoxide of manganese with a saturated solution of potassic chromate containing a little bichromate; the paste is dried and heated somewhat strongly. The combustion is performed with plumbic chromate (or copper oxide) in the usual way, about 5 inches of the chromate mixture being put in the front part of the tube to absorb the nitrous fumes. In performing a combustion, the whole tube is strongly heated, while pure air is passed through it, then the absorbent mixture is allowed to cool to 200°-250° and kept at that temperature during the combustion (Perkin, *C. J.* 37, 457).

Estimation of Nitrogen.

Will and Varrentrapp (*A.* 39, 257) mix the substance with soda lime, that has recently been strongly heated, and put the mixture into a short combustion-tube drawn out to a point at one end. The operation is conducted exactly as in combustion in a closed tube (*v. supra*), the escaping gases being passed into a bulb-apparatus to absorb ammonia. The bulbs contain hydrochloric acid, the NH_3 being weighed as $(NH_4)_2PtCl_6$; or, better, standard hydrochloric or oxalic acid, the amount of NH_3 being then determined by subsequent titration.

If the soda-lime contain nitrate it will evolve NH_3 even when heated with sugar (Schulze a. Kreussler, *Fr.* 12, 362). If in preparing the soda-lime a little $Na_2S_2O_3$ be added before evaporating and strongly heating, small quantities of nitrates and nitrites will be reduced and eliminated as NH_3 (Dittmar, *priv. com.*). Substances rich in nitrogen should be mixed with sugar after weighing.

Unfortunately many organic compounds do not yield all their nitrogen in the form of ammonia when ignited with soda-lime; such are nitroso-, nitro-, azo- and diazo-, compounds, and even some proteïds (Ritthausen, *Fr.* 17, 501; Kreussler, *J.* 1884, 1608); in this case the method of analysis proposed by Dumas is generally used. Modifications of the soda-lime process intended to overcome this difficulty have, however, been proposed. Ruffle (*C. J.* 39, 87) mixes the substance (1 g.) with sulphur (·75 g.) and finely powdered wood charcoal (·75 g.). Soda-lime prepared from NaOH (160 g.), water and CaO (56 g.) is dried and mixed with $Na_2S_2O_3$(21 g.). Two-thirds of the tube is filled with this mixture, containing the substance to be analysed; the remaining third is ordinary soda-lime, which prevents evolution of H_2S. The thiosulphate reduces nitro compounds.

Arnold (*B.* 18, 806) prefers a mixture of soda-lime, sodium formate and $Na_2S_2O_3$.

Dumas (*A. Ch.* [2] 53, 171) heats the substance with oxide of copper and measures the escaping nitrogen. A combustion-tube closed at one end has first some bicarbonate of soda, or, much better, magnesite, put into it; this is followed by pure oxide of copper, a mixture of oxide of copper and the weighed substance, pure oxide of copper, and finally a bright copper spiral —just as in an ordinary combustion; the end of the tube is closed by a cork through which passes a delivery tube dipping under mercury. Before beginning the combustion all the air must be driven out of the tube by carbonic acid; this is effected by heating the magnesite; the combustion is then proceeded with in the ordinary way, and the gaseous products are collected in a graduated tube standing over mercury and containing 50 c.c. of a solution of caustic potash (equal weights of potash and water). The products of combustion are water, carbonic acid, and nitrogen; the two former are stopped by the potash, so that the gas that collects is pure nitrogen; at the end of the experiment the combustion tube still contains nitrogen which must be expelled by heating the magnesite a second time. The eudiometer and its contents is then transferred to a vessel containing air-free water, which takes the place of the mercury and potash. The volume of the nitrogen corrected for pressure and temperature enables one to calculate its weight.

As there is some danger that the magnesite may be all used up in the preliminary expulsion of air from the tube, a convenient modification of this process consists in expelling the air by hydrogen; the hydrogen is got rid of by igniting a little of the copper oxide in the front part of the tube; a complete vacuum is thus formed, and the mercury rises in the delivery tube to the height of the barometer. The combustion is proceeded with in the usual way, and the residual nitrogen expelled by heating the magnesite.

Bicarbonate of soda, $MnCO_3$, or a mixture of Na_2CO_3 and $K_2Cr_2O_7$ may be used instead of magnesite as a source of CO_2. In order that the tube may be used several times without turning out all the copper oxide, C. E. Groves (*C. J.* 37, 504) places the substance intended to evolve CO_2 in a separate tube, 7 inches long, which is attached by a short glass connecting-tube to the end of the combustion-tube, which is in this case open at both ends. A fresh carbonic acid tube is used for each experiment. The CO_2 may also be obtained from marble and HClAq or H_2SO_4, but it is then liable to contain air unless the apparatus be first exhausted by an air-pump (Bernthsen, *Fr.* 21, 63) or heated to boiling (Hufschmidt, *B.* 18, 1441). The nitrogen is frequently contaminated with NO. Frankland a. Armstrong (*C. J.* 21, 77), after reading off the nitrogen, pass up a little oxygen, and, when the resulting NO_2 has been absorbed, they remove the excess of oxygen by potassium pyrogallate. The mean between the volumes of gas before and after this operation is the true volume of nitrogen (Thudichum a. Wanklyn, *C. J.* 22, 293). Apparatus for collecting and measuring the nitrogen have been devised by Zulkowsky (*A.* 182, 296), Schwarz (*B.* 13, 771), Ludwig, (*B.* 13, 883), H. Schiff (*B.* 13, 885), C. E. Groves (*C. J.* 37, 500), Staedel (*Fr.* 19, 452),

Schmitt (*J. pr.* [2] 24, 444), **Gladding** (*Am.* 4, 42), **Hempel** (*Fr.* 17, 409), and **Ilinski** (*B.* 17, 1847). **Frankland a. Armstrong** (*C. J.* 21, 77) connect the tube with a Sprengel's pump, which delivers the gas into a eudiometer at the end of the dropping tube (see also Gibbs, *Fr.* 11, 206; Hempel, *Bn.* 1, 9; Pflüger, *Fr.* 18, 296; Johnson a. Jenkins, *Am.* 2, 27). Explosive substances may be analysed under diminished pressure.

The weight of nitrogen is calculated from its volume with the aid of the annexed table. From the barometric height, corrected for expansion of mercury and of the scale, the vapour pressure of water at the temperature of the nitrogen is deducted; from the corrected pressure and the temperature the weight of nitrogen is at once given by the table.

Pressure of Aqueous Vapour, in mm.

Temp.	10°	11°	12°	13°	14°	15°	16°	17°	18°	19°	20°	21°	22°	23°	24°	25°

Reduction of Barometric Height.

If the barometer has a glass scale, the necessary reduction will be found by multiplying the following numbers by the temperature, viz.:—

mm.	Reduction	mm.	Reduction
720	·123	750	·128
725	·124	755	·129
730	·125	760	·130
735	·126	765	·131
740	·127	770	·132
745	·127	775	·133

Vapour-Pressure of Aqueous KOH.

When nitrogen is measured over aqueous potash, the correction for vapour-pressure is less than that given above, as is seen from the following table, which relates to a solution of 1 pt. of potash in $2\frac{1}{2}$ pts. water (S.G. 1·258).

10°	6·19	18°	10·47
11°	6·58	19°	11·20
12°	7·02	20°	11·97
13°	7·48	21°	12·80
14°	7·99	22°	13·70
15°	8·53	23°	14·62
16°	9·13	24°	15·60
17°	9·77	25°	16·65

(Kreusler, *Fr.* 24, 445).

In the course of an elaborate discussion of the various methods of estimating nitrogen, Kreusler (*Landwirthschaftliche Versuchstationen*, 31, 207; *cf. Fr.* 19, 92; 24, 438) recommends that the copper oxide be mixed with asbestos. Cupric sulphate (150 g.), water (400 g.), and light asbestos (50 g.), are evaporated until almost dry; the mass is then thrown in small quantities into boiling water (2500 g.) containing KOH (160 g.), and finally washed, dried, and heated until red hot. Kreusler also uses copper-asbestos prepared by reducing this copper-oxide-asbestos in place of a copper spiral.

Nitrogen may often be converted into NH_3 by $KMnO_4$ and boiling NaOHAq (Wanklyn, Chapman, a. Smith, *C. J.* 20, 445), or by $KMnO_4$ and fuming H_2SO_4 (Kjeldahl, *Fr.* 22, 370). In the latter case it is better to add $CuSO_4$ (Hilfahrt, C. C 16, 17), benzoic acid, sugar, and mercury (Arnold, *Ar. Ph.* [2] 24, 785). Kreusler recommends a mixture of conc. H_2SO_4 (9 pts.) and P_2O_5 (1 pt.) as a substitute for fuming H_2SO_4 (*v.* also Warington, *C. N.* 52, 162).

Substances containing Halogens.

Determination of Carbon and Hydrogen.

In the combustion of substances containing chlorine white fumes of cuprous chloride might pass into the chloride of calcium tube, and even chlorine might be given off by the action of the oxygen (Städeler, *A.* 69, 335; Kraut, *Fr.* 2, 242); these sources of error may be prevented by placing a roll of silver foil between the copper oxide and the cork into which the chloride of calcium tube is inserted. This part of the tube is kept at a dull red heat throughout the combustion; cuprous chloride and silver form silver chloride and copper.

If the substance contains nitrogen as well as halogens, a copper spiral need not precede the silver spiral.

Determination of Halogens.

This is usually effected by placing 4 c.c. fuming nitric acid and about a gram of silver nitrate in a strong glass tube, then sliding down a little tube containing the weighed substance in such a manner that it may stick to the wet glass and not at once fall into the acid; the open end of the strong glass tube is then fused, drawn off to a stout point and sealed. A little tapping will now cause the tube containing the substance to fall into the acid, after which the whole is heated at 180° for seven hours in a gun-barrel. Aromatic substances require a higher temperature, 250°–300°. Silver chloride (bromide or iodide) is formed, and, after opening the tube, diluting and boiling, it is collected, dried, and weighed (Carius, *A.* 116, 1; 136, 129). A still easier method is that lately proposed by Plimpton and Graves (*C. J.* 43, 119), in which the organic substance is burnt in the flame of a small Bunsen burner; the halogen is left chiefly combined with hydrogen but partly in the free state. The products are sucked through aqueous NaOH, which is then boiled with SO_2 and subsequently mixed with HNO_3. The halogen is then estimated volumetrically (best by sulphocyanide method) or gravimetrically.

Another method is to heat the substance in a combustion tube through which oxygen charged with nitrous fumes is passing (Klason, *B.* 19, 1910).

Halogens may in many cases be determined by strongly heating with lime; with a mixture of Na_2CO_3 and KNO_3 (Volhard, *A.* 190, 40); with Fe_2O_3 (E. Kopp, *B.* 8, 769; Klobulowski, *B.* 10, 290); or with alcoholic KOH; or by reducing with sodium amalgam (Kekulé, *A. Suppl.* 1, 340).

Halogens in the side-chains of aromatic compounds may be estimated by boiling with a saturated alcoholic solution of $AgNO_3$ (Schulze, *B.* 17, 1675).

Table showing the weight in milligrammes of 1 c.c. nitrogen at 10° to 25° C. and 720 to 770 mm. pressure (Dietrich, *Fr.* 5, 38).

Compounds containing Sulphur.

Determination of Carbon and Hydrogen.

In the analysis of compounds containing sulphur there is danger that SO_2 may be absorbed in the weighed tubes. This is obviated by using lead chromate, in the form of small fused lumps, instead of cupric oxide. The $PbCrO_4$ (10 pts.) may be mixed with $K_2Cr_2O_7$ (1 pt.). Sulphur remains in the tube as $PbSO_4$. Volatile substances containing N as well as S must be burnt slowly (V. Meyer a. Städeler, *B.* 17, 1577). According to Ritthausen (*Fr.* 22, 108), reduced lead chromate can be re-oxidised by heating in a current of oxygen. It is of course not necessary to fill the whole tube with lead chromate, the posterior half may contain CuO. A mixture of CuO and $PbCrO_4$ is sometimes used.

Determination of Sulphur.

Sulphur may be estimated by the method of Carius, by heating with fuming HNO_3 in a tube as described for halogens; the sulphuric acid is ppd. by $BaCl_2$. This method cannot usually be employed in the case of organic sulphides, since these are converted into sulphonic acids.

The most rapid method is that of Plimpton, which consists in burning the substance in the flame of a small Bunsen, sucking the products of combustion through dilute NaOHAq, oxidising with Cl, and ppg. as $BaSO_4$ (Morley a. Saint, *C. J.* 43, 401). Or the substance may be burnt in a stream of oxygen and the SO_2 collected in HClAq containing Br (Sauer, *Fr.* 12, 32, 178; Mixter, *Fr.* 22, 581). In this experiment it is better to pass the oxygen through fuming nitric acid so that it may be charged with nitrous fumes (Klason, *B.* 19, 1910). In many cases sulphur may be determined by fusion with a mixture of Na_2CO_3 and KNO_3 or $KClO_3$. In the case of albuminoids it is convenient to evaporate with HNO_3 (10 pts. of S. G. 1·4) before fusing (Kochs, *C. C.* 1886, 894). Oxidation may also be effected by Na_2CO_3 and HgO (Russell, *C. J.* 7, 212).

Phosphorus.

The estimation of phosphorus resembles that of S. It is weighed as $Mg_2P_2O_7$.

Boron.

If compounds containing boron are analysed by combustion with copper oxide the hydrogen will come out too high, owing to the volatilisation of boric acid. This is prevented by using lead chromate instead of cupric oxide (Councler, *J. pr.* [2] 18, 375).

Silicon.

SiO_2 is left behind when non-volatile compounds are heated. Volatile compounds are heated with conc. or fuming H_2SO_4 and $KMnO$; the product is poured into water. The ppd. H_2SiO_3 is freed from traces of manganese by fusion with Na_2CO_3 and KNO_3 (Polis, *B.* 19, 1024).

Alkalis or Alkaline Earths.

In an ordinary combustion these would be left as carbonates, the estimation of carbon thus being too low; but if the substance is thoroughly mixed with $PbCrO_4$ (10 pts.), and $K_2Cr_2O_7$ (1 pt.), the CO_2 will be turned out by CrO_3, the bases being left as chromates. Schaller (*Bl.* [2] 2, 93) mixes the alkaline salts of organic acids with an equal weight of SiO_2 and then with CuO.

The alkaline metals are determined by strongly heating and analysing the inorganic residue.

Silver, Platinum, and Gold

Are determined by strongly heating the substance and weighing the metallic residue.

Explosive Substances

Must be well mixed with CuO before being put into a combustion tube; very explosive substances are analysed *in vacuo*.

Combustion with platinum black.

Kopfer (*C. J.* 29, 660) introduced the use of finely divided platinum as a carrier of oxygen. The anterior half of a combustion-tube is filled with platinum black intimately mixed with asbestos, the posterior half of the tube contains the weighed substance in a boat; air or oxygen is passed through the tube, the combustion being conducted in the usual way.

PROXIMATE ANALYSIS.

Separation of Mixtures.

A complete account of proximate organic analysis would include descriptions of the properties of every known organic substance, since the methods to be adopted vary in almost every case.

The simplest method is separation by solvents which dissolve some but not all of the components of a mixture; when solid substances have been dissolved, they may usually be further purified by crystallisation.

An unknown mixture is treated with water; the insoluble portion is shaken with dilute H_2SO_4 which dissolves bases, then with dilute Na_2CO_3 which dissolves acids, then with dilute NaOH which dissolves phenols; the bases are ppd. by adding KOH to the H_2SO_4Aq; the acids and phenols by acidifying the alkaline solutions containing them.

The neutral residue is fractionally distilled and the various portions are boiled with alcoholic KOH which saponifies compound ethers, and gives a pp. of KCl in the case of fatty chloro-derivatives. The alcohol is distilled off together with volatile alcohols, &c., and the residue treated with water, which dissolves salts of acids that may have been formed. The insoluble residue is a hydrocarbon, high-boiling alcohol, alkyl oxide, ketone, haloid aromatic compound, &c.; the hydrocarbon will usually be left on treating the residue with cold H_2SO_4 if aromatic chloro-derivatives are absent.

The aqueous extract of the original substance is neutralised (if necessary) and distilled. The distillate is treated with K_2CO_3 which separates alcohols, lactones, methyl acetate &c. The residue is made alkaline by KOH and distilled: bases pass over; it is then acidified with H_2SO_4 and distilled: volatile acids pass over. The residue is exactly neutralised and neutral substances are extracted by ether, chloroform, and benzene, the aqueous residue is acidified and non-volatile acids are extracted by these solvents; the residue is now made alkaline and again extracted, finally it is evaporated to dryness, and, if any organic matter is still present, extracted with solvents. (*V.* also Alkaloids, p. 120; Acids, p. 56.)

Many substances, even of very high boiling point, distil in a current of steam.

Detection of radicles.

Hydroxyl.—Compounds containing OH evolve HCl when treated with PCl_3 (p. 54); but if PCl_5 is used chlorination may occur *e.g.* $C_6H_5OMe + PCl_5 = C_6H_4Cl.OMe + PCl_3 + HCl$. AcCl acts upon hydroxylic compounds with evolution of HCl; when water is added to the product the acetyl derivatives of alcoholic hydroxyls are not affected, but CO.OAc is converted into CO.OH. AcCl acts also upon amines in the following way:

$$C_6H_5NH_2 + AcCl = C_6H_5NAcH + HCl.$$

BzCl and Ac_2O also displace hydroxylic hydrogen by acid radicles. In compounds whose molecules do not contain NH_2 or NH the number of hydroxyls (other than those in carboxyls) present can be determined by estimating the acetic acid obtained by saponifying the product after treatment with water. The groups C.CO.NH and $C.CO.CH_2$ in many cases act as if they contained hydroxyl and were C.C(OH):N and C.C(OH):CH.

Very dilute, colourless solutions of Fe_2Cl_6 give a distinct colouration with compounds containing alcoholic hydroxyl (Landwehr, *B.* 19, 2726).

Zinc ethide evolves ethane gas when mixed with compounds containing hydroxyl or amidogen (Japp, *C. J.* 37, 665); compounds containing imidogen evolve gas when heated with $ZnEt_2$ at 100° (Japp, *C. J.* 39, 224). (*V.* also Alcohols and Acids.)

Amidogen is indicated by the reactions just mentioned, and also by the readiness with which methyl can be introduced by heating with MeI. Methyl iodide does not act upon hydroxyl except in presence of an alkali. Compounds containing NH_2 evolve nitrogen when heated with nitrous acid.

The number of amidogens in the molecule of a compound may be found by treating the substance with KNO_2 and H_2SO_4; the escaping nitrogen is freed from NO by $FeSO_4$ and then measured (Sachsse a. Kormann, *Fr.* 14, 380). In easily diazotised aromatic amido compounds, the number of amidogens may be determined by dissolving in conc. HClAq and titrating with a normal solution of KNO_2, until a drop of the solution gives a blue colour with KI and starch (Green a. Evershed, *S. C. I.* 5, 633).

Imidogen is indicated by the production of a nitrosamine when treated with nitrous acid. (See also Amines, Amido-acids, Amides.)

Carbonyl is indicated by the reaction with phenyl-hydrazine and hydroxylamine (p. 107).

Carboxyl is indicated by the easy production of metallic salts, and by the splitting off of CO_2 when the substance is heated alone or with lime.

Want of saturation is indicated by instant bleaching of bromine.

Acetylenic hydrogen is indicated by the formation of explosive pps. with ammoniacal cuprous chloride or silver nitrate.

Nitroxyl.—Nitro compounds may be reduced to compounds containing amidogen. The number of nitroxyls is found by reducing with standard $SnCl_2$ and titrating with iodine (Limpricht, *B.* 11, 35).

Methoxyl. The number of MeO groups can be found by boiling with aqueous HI (S.G. 1·68) the distillate (MeI) being received in alcoholic $AgNO_3$ and the resulting AgI weighed (Zeisel, *M.* 6, 989).

Halogens in the side chains of aromatic compounds can be estimated by boiling with a saturated alcoholic solution of $AgNO_3$ (Schulze, *B.* 17, 1675).

ANAMIRTIN $C_{19}H_{24}O_{10}$(?). Occurs in grains of cocculus indicus (*Anamirta cocculus*) along with picrotoxin (*q. v.*), picrotin, and glyceryl stearate (Barth a. Kretschy, *Sitz. B.* [ii] 81, 7; Francis, *A.* 42, 254). Short needles (from water), insol. benzene; becomes brown at 260°. Neither bitter nor poisonous.

ANCHOÏC ACID = Azelaïc acid.

ANCHUSIN *v.* Alkanet.

ANDROMEDOTOXIN $C_{31}H_{51}O_{10}$ [228°]. A poisonous substance in *Rhododendron ponticum* (Zaaijer, *R.* 5, 313).

ANEMONE.—The plants *Anemone nemorosa*, *A. pratensis*, and *A. pulsatilla* when distilled with steam yield anemonin, anemone-camphor, anemonic acid, and a yellowish oil, which are extracted by shaking the distillate with chloroform (Löwig a. Weidmann, *P.* 46, 45; Schwarz, *Mag. Pharm.* 10, 193; 19, 168; Fehling, *A.* 38, 27[illegible]; Dobraschinsky, *J. Ph.* [4] 1, 319; H. Beckurts, *C. C.* 1885, 776).

Anemonin $C_{15}H_{12}O_6$. [150°]. Trimetric crystals; sol. $CHCl_3$, sl. sol. alcohol and water, insol. ether. Reduces $AgNO_3$.—$PbOC_{15}H_{12}O_6$.

Anemonic acid. Amorphous powder; insol. water, alcohol, and ether.

Anemone-camphor. Trimetric prisms; unstable.

ANETHOL $C_{10}H_{12}O$ *i.e.* $CH_3O.C_6H_4.CH:CH.CH_3$ [1:4]. *Methyl p-propenyl-phenol.* [21·3°]. (232°). S.G. ^{21} ·987. μ_H 1·6167 (Gladstone, *C. J.* 49, 623). R_∞ 77·97 (Nasini, *G.* 15, 93). S.V.S. 149·34.

Occurrence.—In oil of anise (from *Pimpinella anisum*) together with a terpene, in China or star anise (from *Illicium anisatum*), in fennel (*Anethum fœniculum*), and tarragon (*Artemisia Dracunculus*) (Laurent, *Revue Scient.* 10, 6; Gerhardt, *A.* 44, 318; 52, 401; Cahours, *A. Ch.* [3] 2, 274).

Formation. — Together with CO_2 when $CH_3O.C_6H_4.CH{:}C(CH_3).CO_2H$ is heated (Perkin, *C. J.* 32, 669).

Properties.—Plates; v. sl. sol. water, v. e. sol. alcohol and ether. Easily polymerised.

Reactions. — 1. *Oxidation* produces anisic aldehyde, anisic acid, and acetic acid (Hempel, *A.* 59, 104). — 2. *Alcoholic potash* produces $C_{16}H_{18}O_3$ [87°] and $C_{14}H_{16}O_2$ [65°]; the latter forms an acetyl derivative [40°] (Landolph, *B.* 13, 147; *C. R.* 81, 97; 82, 226).—3. *Nitrosyl chloride* produces $C_6H_4(OMe).C_3H_5NOCl$ which reduces to $C_6H_4(OMe).C_3H_6NH_2$ (Tönnies, *B.* 12, 169).—4. *Nitrous acid* produces two bodies: $C_6H_4(OMe).C_3H_5N_2O_3$ and $C_6H_4(OMe).C_3H_3N_2O_2$ [97°]. The former may be reduced to $C_6H_4(OMe).C_3H_5(OH)NH_2HCl$, the latter to $(CH_3O.C_6H_4.C_3H_3)_2N_4O_3$ (?) (T., *B.* 13, 1845).—5. *Boron fluoride* produces C_6H_5OMe, and a liquid $C_{11}H_{16}O$ (c. 227°) (L., *C. R.* 86, 601).—6. HI at 260° forms C_8H_{16} (150°) and $C_{12}H_{22}$ (210°) (L., *C. R.* 82, 849). — 7. PCl_5 forms $C_{10}H_{11}ClO$, [–3°], (229°), S.G. $^{\underline{20}}$ 1·191 (Landolph); Ladenburg gives different properties for chloro-anethol, viz.: [6°], (258°), S.G. $^{\underline{0}}$ 1·125.—8. Br forms $C_{10}H_{12}Br_2O$, [65°] (Ladenburg, *A. Suppl.* 8, 87; *Z.* [2] 5, 576).

Anethol-tetrahydride $C_{10}H_{16}O$. *Anethol-camphor.* [190°–193°]. Has a camphor-like smell. Formed together with anisic aldehyde by the oxidation of anethol with HNO_3 (L.). Smells like camphor. On oxidation with $K_2Cr_2O_7$ it gives an acid which forms long needles of melting point [175°] (anisic acid ?).

Anethol-hexahydride $C_{10}H_{18}O$. *Anethol-borneol* [19°]. (198°). Formed together with an acid by heating anethol-tetrahydride with alcoholic KOH (L.). Long slender needles. Insol. KOHAq.

Anethol dihydride = *Methyl*-Propyl-phenol.

Anethoïn $(C_{10}H_{12}O)_n$. *Anisoïn.* [140°–145°]. From anethol by shaking with a little H_2SO_4 or P_2O_5 (C.), or by the action of $SnCl_4$ (Gerhardt, *J. pr.* 36, 267), I in KIAq (Will a. Rhodius, *A.* 65, 230) or BzCl (Kraut a. Uelsmann, *J. pr.* 77, 490). Prepared by distilling oil of anise with conc. H_2SO_4. Needles (from ether); insol. water and alcohol. Decomposed on distillation into liquid metanethol and solid isanethol.

Metanethol $(C_{10}H_{12}O)_n$. [132°]. (above 300°). Prepared by heating anethol (210 g.) with $ZnCl_2$ (750 g.) in a copper retort; in a few minutes white fumes appear in the receiver, superheated steam is then passed into the retort; the metanethol then passes slowly over. The yield is 5 to 10 p.c. (Perrenoud, *A.* 187, 63). Silky needles (from ether). Not volatile with steam at 100°.

Metanethol sulphonic acid $(C_{10}H_{11}(SO_3H)O)_n$. Formed by conc. H_2SO_4 in the cold. Salts.—CaA'_2aq: laminæ.—BaA'_2.

Chloride $C_{10}H_{11}(SO_2Cl)O$. [183°].

Liquid metanethol $(C_{10}H_{12}O)_n$. (233°). S.G. $^{\underline{18}}$ ·971. Formed by distilling anethoïn (Kraut a. Schlun, *Z.* 1868, 359); and by distilling anethol with $ZnCl_2$. Converted by conc. H_2SO_4 into anethoïn. At 320° it partially changes to isanethol.

Sulphonic acid.—$(C_{10}H_{11}(SO_3H)O)_n$ (Gerhardt, *J. pr.* 36, 275). Salt.—CaA'_2 aq: gummy.

Isanethol $(C_{10}H_{12}O)_n$. A viscid mass left in the retort when anethoïn is distilled; conc. H_2SO_4 converts it into anethoïn.

ANGELICA, OIL OF. The seeds of *Angelica archangelica* yield an essential oil (S.G. $^{\underline{0}}$ ·872; $[\alpha]_D$ 13° 8′) containing a terpene, $C_{10}H_{16}$, (175°), S.G. $^{\underline{0}}$ ·833, $[\alpha]_D = 12°$ 38′. The rotatory power of this terpene is reduced to 4° 52′ by heating for 432 hours at 100°; it is readily polymerised and easily oxidised (Naudin, *C. R.* 93, 1146). The essential oil also contains methyl-ethyl-acetic and oxymyristic acids (R. Müller, *B.* 14, 2476). The roots of *Angelica archangelica* yield an essential oil (S.G. $^{\underline{0}}$ ·875) containing a terpene (166°), S.G. $^{\underline{0}}$ ·870, $[\alpha] = 2°$ 50′. This terpene polymerises readily under the influence of heat or sodium (Naudin, *C. R.* 96, 1152; *Bl.* [2] 39, 406).

ANGELIC ACID $C_5H_8O_2$ *i.e.* $CH_2{:}CH.CH(CH_3).CO_2H$. *Pentenoic acid.* Mol. w. 100. [45°]. (185° i.V.).

Occurrence. — In the root of *Angelica archangelica* (Buchner, *A.* 42, 226). Oil of chamomile (*Anthemis nobilis*) may be separated by fractionating into isobutyl isobutyrate, isobutyl angelate, amyl angelate, and amyl tiglate; the residue contains hexyl tiglate and anthemol, $C_{10}H_{16}O$ (Köbig, *A.* 195, 95). Angelic acid is formed, together with laserol by heating laserpitin with alcoholic KOH (Feldmann, *A.* 135, 236).

Preparation.—1. Angelica root (50 lbs.) is boiled with lime (4 lbs.) and water, and the filtrate acidified with H_2SO_4 and distilled (Meyer a. Zenner, *A.* 55, 317).—2. Oil of chamomile is saponified by alcoholic KOH (Kopp, *A.* 195, 81; Pagenstecher, *A.* 195, 108; Beilstein a. Wiegand, *B.* 17, 2261).—3. Sumbul or moschus root contains a resin which when boiled with alcoholic KOH yields angelic and methyl-crotonic acids (Reinsch, *Jahrb. pr. Pharm.* 7, 79; E. Schmidt, *Ar. Ph.* [3] 24, 528).

Properties.—Monoclinic prisms or needles; sl. sol. cold water, v. sol. hot water, alcohol, and ether.

Reactions.—1. *Hydriodic acid* at 190° reduces it to valeric acid (Ascher, *Z.* [2] 6, 217).—2. *Potash-fusion* produces acetate and propionate (Demarçay, *C. R.* 80. 1400).—3. *Bromine* forms a dibromide [86°].—4. Conc. H_2SO_4 converts it into tiglic acid.—5. $KMnO_4$ gives CO_2 and aldehyde (B. a. W.).

Salts. — BaA'_2 4½aq: crystalline mass. — CaA'_2 2aq: long needles, much more soluble in cold, than in hot, water. — AgA′: feathery crystals, sl. sol. water.—PbA'_2: crystals, sl. sol. water.

Ethyl-ether.—EtA′. (141·5°). S.G. $^{\underline{0}}$ ·935.

Isobutyl ether C_4H_9A'. (177°).

Isoamyl ether $C_5H_{11}A'$. (201°).

Anhydride $(C_5H_7O)_2O$. Oil (Chiozza, *A. Ch.* [3] 39, 210).

Hydriodide $CH_3.CHI.CH(CH_3).CO_2H$. [46°]. *Iodo-valeric acid.* Prisms. Formed by very conc. HI.

Constitution.— Angelic acid is isomeric with allyl-acetic acid, $CH_2{:}CH.CH_2.CH_2.CO_2H$, methyl-crotonic or tiglic acid $CH_3.CH{:}C(CH_3).CO_2H$, β-β-di-methyl-acrylic acid $(CH_3)_2C{:}CH.CO_2H$ (Ustinoff, *J. pr.* [2] 34, 484), propylidene-acetic acid, $CH_3.CH_2.CH{:}CH.CO_2H$, and tetra-methylene carboxylic acid.

The same valeric acid, (173°-175° uncor.), S.G. ^{15} ·941, is formed by reducing the hydriodides of angelic and of tiglic acids by Zn and H_2SO_4. It is probably $CH_3.CH_2.CH(CH_3).CO_2H$ (Schmidt, *B.* 12, 252). Angelic acid changes when long kept, or when treated with $AgNO_3$, into tiglic acid, and hence the two acids have probably the same carbon skeleton. The hydriodide of angelic acid is, however, different from that of tiglic acid, $CH_3.CH_2.CI(CH_3).CO_2H$. This would be explained by assigning to angelic acid the formula $CH_2{:}CH.CH(CH_3).CO_2H$, its compound with HI being $CH_3.CHI.CH(CH_3).CO_2H$. The latter iodo-valeric acid is not $CH_2I.CH_2.CH(CH_3).CO_2H$ for it gives no lactone on neutralisation with Na_2CO_3, but butylene $CH_3.CH{:}CH.CH_3$ (Fittig, *A.* 216, 161). An alternative formula, $CH_2{:}CEt.CO_2H$, would form with HI either $CH_2I.CHEt.CO_2H$ or, more probably, $CH_3.CIEt.CO_2H$; sodium carbonate would convert the latter into an oxy-acid, or back into angelic acid, while the former would give the butylene $CH_2{:}CH.CH_2.CH_3$.

ANGELICO-BENZOIC OXIDE $C_{12}H_{12}O_3$ *i.e.* $C_5H_7O.O.Bz$. From potassium angelate and BzCl (Chiozza, *A.* 86, 260). Oil.

ANGELICO LACTONES. $C_5H_6O_2$. β-acetyl-propionic (levulic) acid splits up on distillation into H_2O and a mixture of these lactones, transition compounds being doubtless the two isomeric oxy-acids $CH_3.C(OH){:}CH.CH_2.CO_2H$ and $CH_2{:}C(OH).CH_2.CH_2.CO_2H$. They are dried over K_2CO_3 and separated by fractional distillation (Wolff, *A.* 229, 249; *B.* 20, 425). The (α) lactone is converted into the (β) modification by combining it with HCl and distilling the product. Both lactones combine with bromine, and both are changed to β-acetyl-propionic acid by boiling with water or by treatment with cold aqueous baryta. This reaction is easily explained, for the oxy-acids $CH_3.C(OH){:}CH.CH_2.CO_2H$ and $CH_2{:}C(OH).CH_2.CH_2.CO_2H$ into which the lactones should be converted, would both change (by Erlenmeyer's rule) into $CH_3.CO.CH_2.CH_2.CO_2H$.

(α)-Angelico-lactone $CH_3.C{:}CH.CH_2.CO.O$

[18°]. (168°). V.D. 3·6. S. 5 at 15°. Is also formed by the action of water on the bromide of β-bromo-β-acetyl-propionic acid. Colourless neutral liquid, gradually turns yellow. It has a pleasant odour and bitter taste. At 0° it solidifies to white needles which are not hygroscopic and are volatile. The lactone dissolves in most solvents. It is separated by K_2CO_3 from its aqueous solution. If left a few hours with cold water the liquid becomes acid.

Reactions.—1. NH_3 converts it into β-acetyl-propion-amide.—2. Combines with bromine in CS_2 forming the lactone of di-bromo-oxy-valeric acid (*q. v.*).—3. Combines with HCl forming the lactone of chloro-oxy-valeric acid (*q. v.*).

(β)-Angelico-lactone  $CH_2{:}C.CH_2.CH_2.CO.O.$

(209°) at 750 mm. (84°) at 25 mm. S.G. ^{0} 1·1084. Colourless neutral liquid. It does not solidify at −15°. It is partly converted into its (α) isomeride every time it is distilled under atmospheric pressure. Miscible with water, has a pleasant odour. May be left for 4 hours with cold water without production of an acid.

Reactions.—1. Boiled with water it is very slowly converted into levulic acid.—2. Combines with bromine in CS_2.—3. Does not combine with HCl.

ANGELYL. The radicle C_5H_7O. Also applied by Hofmann to monovalent Pentenyl (*q. v.*).

ANGUSTURA OIL $C_{13}H_{24}O$. (266°). S.G. ·93. Obtained by distilling true Angustura bark (*Cusparia febrifuga*) with steam (Herzog, *J.* 1858, 444). The bark contains also cusparine and gasipeïne (*q. v.*).

ANHYDRIDES.—*Oxides which react with water to form acids* (*q. v.*), *or are obtained from acids by withdrawing water, or which react with basic oxides to produce salts: e.g.*

$SO_3 + H_2O = H_2SO_4$; $2HNO_3 - H_2O = N_2O_5$;
$SO_3 + BaO = BaSO_4$; $CrO_3 + BaO = BaCrO_4$.

Solutions of anhydrides in ether or other liquid quite free from water do not exhibit an acid reaction towards litmus. The greater number of the oxides of non-metals are anhydrides; the metallic oxides which belong to this class are usually those containing the greatest quantity of oxygen relatively to the metal. The more negative the character of an element the more do the lower oxides of that element exhibit the properties of anhydrides; the most positive elements do not form anhydrides. Metallic anhydrides do not, as a rule, produce acids by reacting with water, but most of them may be obtained from the corresponding hydrated oxides, having feebly-marked acid characters, by the action of heat; *e.g.* Nb_2O_5, PtO, PtO_2, TiO_2, SnO_2, &c. The formation of salts from these anhydrides is usually accomplished by fusing them with more basic oxides or hydrates; *e.g.* $Ta_2O_5 + K_2O$ (fused) $= K_2Ta_2O_6$; in some cases the metallic anhydride dissolves in strong aqueous potash or soda to form a salt; *e.g.* $Au_2O_3 + 2KOHAq = K_2Au_2O_4Aq + H_2O$. A definite connexion can be traced between the position of an element in the classificatory scheme founded on the periodic law and the existence or non-existence of anhydrides containing that element (*v.* Oxides; also Classification; and Periodic Law).

As a broad rule the anhydrides of the polybasic acids may be obtained from these acids by the action of heat (the anhydrides are usually the final products, before they are reached new acids are produced), but this rule has exceptions; *e.g.*, P_2O_5 cannot be obtained by heating H_3PO_4. The anhydrides of monobasic acids are usually obtained indirectly, often by the action of an acid chloride on a salt, *e.g.* $ClCl + HgClO = HgCl + Cl_2O$ (this method is largely used in preparing organic anhydrides, *v. next article*); these anhydrides are sometimes obtained from their acids by withdrawing water by the action of dehydrating agents; *e.g.* $2HNO_3 + P_2O_5 = N_2O_5 + P_2O_5H_2O$. A few anhydrides are produced by heating salts of the corresponding acids; *e.g.* $FeSO_4$ when heated in air forms $Fe_2S_2O_9$ and this on further heating gives Fe_2O_3 and $2SO_3$.

Besides their characteristic reactions with water and basic oxides, many anhydrides combine with normal salts to produce 'acid' salts (*v.* Salts); *e.g.* $K_2CrO_4 + CrO_3 = K_2Cr_2O_7$. $K_2WO_4 + WO_3 = K_2W_2O_7$. Many of the non-metallic anhydrides combine with their own or other acids to form new acids; *e.g.* the following compounds are thus produced, $(HNO_3)_2N_2O_5$, $H_2SO_4SO_3$, $HClSO_3$, HSO_2NO_3, &c. A few anhydrides react with basic oxides to form salts not of their own but of other acids; *e.g.*, N_2O reacts with Na_2O_2Aq to produce $NaNO_2Aq$ (not NaNO); such anhydrides seem to be obtainable, indirectly, from more than one acid, thus N_2O is got by heating HNOAq or by heating solid NH_4NO_3.

Most anhydrides may be regarded as constituted of two or more acid radicles united by oxygen atoms; on this view such formulæ as these would be applicable:—$NO_2.O.O_2N$; Cl.O.Cl, &c. The mutual relations between acids and anhydrides are repeated to a great extent in the relations of basic hydrates, or hydroxides, to their oxides; *e.g.* $Fe_2O_6H_6$ when heated yields $3H_2O$ and Fe_2O_3; CaO when added to H_2O produces CaO_2H_2, &c.

At one time the name anhydride included both base-producing and acid-producing oxides; then the former class was distinguished as basic-anhydrides; but now the name is almost universally employed with the meanings given to it in this article. The following are the best marked anhydrides containing metals:—Sb_2O_3, Sb_2O_5; As_2O_3, As_2O_5; (? Bi_2O_5); CrO_3; (? Di_2O_5); Au_2O_3; Ir_2O_3; PbO_2; MnO_2; MoO_3; Nb_2O_5; OsO_4; PtO, PtO_2; Ta_2O_5; SnO, SnO_2; TiO_2; WO_3; UO_3; V_2O_4, V_2O_5; ZrO_2. The sulphides, or hydrosulphides, of certain elements react with the anhydrides of thio-acids; *e.g.* As_2S_3 dissolves in KHSAq to form $KAsS_2Aq$, but the acid corresponding to this thio-arsenite is unknown; again, WS_3 dissolves in KHSAq to form K_2WS_4Aq, which reacts as the potassium salt of thio-tungstic acid (H_2WS_4), which acid has not itself been prepared. The thio-acid corresponding to the thio-anhydride SnS_2, viz. H_2SnS_3, has been prepared; CS_2 again is the thio-anhydride of thio-carbonic acid H_2CS_3. It is not, however, customary to apply the term anhydride to any sulphides even when an acid, or a series of salts, can be obtained from them. M. M. P. M.

ANHYDRIDES, ORGANIC.—The anhydride of an organic substance is a body derived from it by elimination of water. The water may be derived from one molecule, or several molecules may become united in the process; in the latter case 'condensation' is said to take place a term which is also used when closed chains are produced. A molecule of water may be derived:

A. From two carboxyls.
B. From one carboxyl and one hydroxyl.
C. From two hydroxyls.
D. From one hydrogen and one hydroxyl.
E. From carboxyl and amidogen.
F. From carbonyl and amidogen.
G. From hydroxyl and amidogen.

A. From two Carboxyls.

Acid Anhydrides.

Formation.—1. On application of heat most monocarboxylic acids distil undecomposed, while di-carboxylic acids in which the carboxyls are attached to adjacent atoms of carbon give anhydrides, *e.g.*

$$C_2H_4\left\langle\begin{matrix}CO.OH\\CO.OH\end{matrix}\right. = C_2H_4\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle O + H_2O.$$

When the carboxyls are attached to the same atom of carbon, CO_2 is split off:

$$CH_3.CH(CO_2H)_2 = CH_3.CH_2.CO_2H + CO_2.$$

2. Anhydrides of monobasic acids are got by the action of acid chlorides on alkaline salts (Gerhardt, *A. Ch.* [3] 37, 285). Mixed anhydrides of monobasic acids may be got in the same way. Instead of the alkaline salt the free acid may be used (Linnemann, *A.* 161, 169). An acid heated with its chloride gives its anhydride in the following cases amongst others: acetic, trichloro-acetic, butyric, benzoic, and succinic acids. Acetyl chloride heated with dibasic acids gives anhydrides of the dibasic acid in the following cases amongst others (a mixed anhydride is perhaps first formed): succinic, chloro-succinic, bromo-succinic, maleïc, acetyl-malic, diacetyl tartaric, diacetyl racemic, citraconic, itaconic, camphoric, phthalic and diphenic acids. These anhydrides of dibasic acids readily absorb water from the air forming the corresponding hydrates, from which, however, they may be separated by chloroform which dissolves the anhydrides only. Benzoyl chloride acts like acetyl chloride. In neither case are mixed anhydrides formed.

Acetic anhydride at 120°–150° also converts dibasic acids into their anhydrides, *e.g.*: succinic, camphoric, phthalic, and diphenic acids (Anschütz, *A.* 226, 12).

3. Anhydrides are also formed by the action of lead nitrate on acid chlorides (Lachowicz, *B.* 17, 1281), *e.g.*:

$$2AcCl + Pb(NO_3)_2 = Ac_2O + PbCl_2 + N_2O_5.$$

4. By passing phosgene over heated salts (Hentschel, *B.* 17, 1285):

$$2NaOAc + COCl_2 = Ac_2O + 2NaCl + CO_2.$$

5. By warming the chlorides of the acids with dry oxalic acid, *e.g.* $2Ph.COCl + H_2C_2O_4 = (Ph.CO)_2O + 2HCl + CO_2 + CO$ (Anschütz, *A.* 226, 14).

Reactions.—1. Simple anhydrides may usually be *distilled* or sublimed, but mixed anhydrides such as BzOAc are split up by heat into two simple ones: $2BzOAc = Bz_2O + Ac_2O$.—2. They are insoluble in *water*, but slowly converted by it into the corresponding acid; a conversion that is more rapidly effected by alkalis.—3. *Alcohol* forms ethyl ethers of the corresponding acids.—4. *Ammonia* forms an amide and an ammonium salt: $Ac_2O + 2NH_3 = AcNH_2 + AcONH_4$, or, in the case of anhydrides of dicarboxylic acids, an amic acid.—5. *Sodium-amalgam* reduces them to aldehydes and alcohols (Linnemann, *A.* 148, 249).—6. PCl_5 forms $POCl_3$ and acid chlorides.—7. Heated with NaOAc in sealed tubes at 200° some anhydrides yield ketones (Perkin, *C. J.* 49, 325):

$$CH_3.CO_2Na + (CH_3CO)_2O = CH_3.CO.CH_3 + CO_2 + CH_3.CO_2Na.$$

$$CH_3.CO_2Na + (C_3H_7CO)_2O = C_3H_7.CO.CH_3 + CO_2 + C_3H_7.CO_2Na.$$

Intermediate addition-products, such as $CH_3.C(O.CO.C_3H_7)_2.ONa$, are perhaps the cause of this reaction.

B. From Hydroxyl and Cardoxyl.

This is the ordinary process of etherification:

$$EtOH + CH_3.CO_2H = H_2O + CH_3.CO.OEt.$$

When hydroxyl and carboxyl are both present in the same molecule, spontaneous etherification may take place, the reaction taking place between two molecules, as in the formation of lactide, $O<\begin{matrix}CHMe.CO\\CO.CHMe\end{matrix}>O$, from lactic acid $HO.CHMe.CO_2H$, or by splitting off water from one molecule, *e.g.*

$$CH_3.CH(OH).CH_2.CH_2.CO_2H = CH_3.CH.CH_2.CH_2.CO.\underbrace{O.}$$

In the latter case the alcoholic part of the molecule etherifies the acid part, and the product is called a lactone (*v.* LACTONES). Hydroxyl in the γ and δ positions gives rise to lactones.

C. FROM TWO HYDROXYLS.

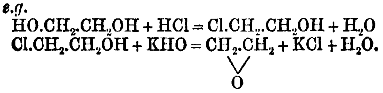
The elimination of water between two hydroxyls in different molecules produces an oxide or simple ether. The result is brought about by first forming an intermediate compound, *e.g.*:

$EtOH + H_2SO_4 = EtO.SO_3H + H_2O$

$EtO.SO_3H + EtOH = EtOEt + H_2SO_4$ (*v.* ETHER).

When two hydroxyls are attached to one atom of carbon they usually split off water spontaneously, producing carbonyl.

Two hydroxyls attached to contiguous atoms of carbon may give rise to an oxide or internal ether, an intermediate body being first prepared, *e.g.*



$$HO.CH_2.CH_2OH + HCl = Cl.CH_2.CH_2OH + H_2O$$
$$Cl.CH_2.CH_2OH + KHO = \underset{\diagdown O \diagup}{CH_2.CH_2} + KCl + H_2O.$$

D. FROM ONE HYDROGEN AND ONE HYDROXYL.

Water can be eliminated by the union of hydroxyl with hydrogen when they are attached to adjacent atoms of carbon. This readily occurs with β-oxy acids, *e.g.*:

$$CH_2(OH).CH_2.CO_2H = H_2O + CH_2:CH.CO_2H.$$
$$C_6H_5.CH(OH).CH_2.CO_2H = H_2O + C_6H_5.CH:CH.CO_2H.$$

E. FROM CARBOXYL AND AMIDOGEN.

Water can be formed either from the hydroxyl and hydrogen, *e.g.*

$$C_6H_4<\begin{matrix}CO.CO.OH\\NH_2\end{matrix} = H_2O + C_6H_4<\begin{matrix}CO\\NH\end{matrix}>CO$$

or from the oxygen of the carbonyl and hydrogen:

$$C_6H_4<\begin{matrix}CO.CO.OH\\NH_2\end{matrix} = H_2O + C_6H_4<\begin{matrix}CO\\N\end{matrix}>C.OH.$$

Compounds resulting from the first mode of dehydration are called lactams, those resulting from the second mode of dehydration being termed lactims.

It is very difficult to say which formula best represents a given compound; Baeyer considers that the arrangement represented by the lactim is the more stable, but that before undergoing chemical reactions it usually changes to the transition or labile condition represented by the lactam. The prefix *pseudo* is frequently applied to distinguish a lactam from a lactim. In the aromatic series the elimination of water takes place spontaneously when the two side-chains are in the ortho position, and when the condensation can produce a ring, containing 5 or 6 atoms.

Thus $C_6H_4<\begin{matrix}CH:CH.CO_2H\\NH_2\end{matrix}$ condenses to $C_6H_4<\begin{matrix}CH:CH\\N\text{===}\end{matrix}>C.OH$ while $C_6H_4<\begin{matrix}CH_2.CH_2.CH_2.CO_2H\\NH_2\end{matrix}$ does not produce an anhydride.

F. FROM CARBONYL AND AMIDOGEN.

The case in which carbonyl forms part of carboxyl has already been mentioned.

Mono-alkoyl-*o*-diamines and *o*-amido-alkoylphenols exhibit a tendency to split off water and form *Anhydro compounds*, *e.g.*

$$C_6H_4<\begin{matrix}NH.CO.CH_3\\NH_2\end{matrix} = H_2O + C_6H_4<\begin{matrix}NH\\N\end{matrix}>C.CH_3$$

$$C_6H_4<\begin{matrix}O.CO.C_6H_5\\NH_2\end{matrix} = H_2O + C_6H_4<\begin{matrix}O\\N\end{matrix}>C.C_6H_5$$

(Hübner, *A.* 208, 278; 209, 339; 210, 328). The first class of compounds may be viewed as amidines. These anhydro-compounds are formed: (1) From aromatic alkoylamides or alkyl phenols by nitration and reduction with tin and glacial acetic acid. (2) From [1:2] amido- (or oxy) nitro-compounds by heating with acid chlorides or anhydrides, and reducing the product. (3) From *o*-diamines or *o*-amido-phenols by heating with acid chlorides or anhydrides.

G. FROM HYDROXYL AND AMIDOGEN.

Alkyls can be introduced into amidogen by heating an amine with an alcohol or phenol, especially in presence of dehydrating agents: thus aniline boiled with (β)-naphthol gives phenyl-(β)-naphthylamine.

ANHYDRO-ACET-DI-AMIDO-BENZENE *v.* ETHENYL-PHENYLENE-DIAMINE.

ANHYDRO-ACET-DI-AMIDO-BENZOIC ACID *v.* ETHENYL-DI-AMIDO-BENZOIC ACID.

ANHYDRO-ACETYL- *v.* ETHENYL-.

ANHYDRO-DI-ACETYL-ACETAMIDIL *v.* ACETAMIDINE.

ANHYDRO-DI-ACETYL-ACETAMIDINE *v.* ACETAMIDINE.

ANHYDRO-*o*-AMIDO-PHENOL-ACETO-ACETIC ETHER *v.* PROPENYL-*o*-AMIDO-PHENOL *ω*-CARBOXYLIC ETHER.

ANHYDRO-AMIDO-PHENOXY-ACETIC ACID *v.* GLYCOLLIC ACID.

ANHYDRO-AMIDO-TOLYL-OXAMIC ACID *v.* DI-OXY-METHYLQUINOXALINE.

ANHYDRO-ATROPINE *v.* ATROPYL-TROPEÏN.

ANHYDRO-BENZ- *v.* BENZENYL-.

ANHYDRO-BENZ-DIAMIDO-BENZENE *v.* BENZENYL-PHENYLENE-DIAMINE.

ANHYDRO-BENZ-DIAMIDO-TOLUENE *v.* BENZENYL-TOLYLENE-DIAMINE.

ANHYDRO-BENZ-DI-AMIDO-TOLUIC ACID *v.* BENZENYL-PHENYLENE-DIAMINE CARBOXYLIC ACID.

ANHYDRO-BENZOYL- *v.* BENZENYL-; or named as derivatives of benzamidine.

ANHYDRO-BENZOYL-AMIDO-DI-TOLYL-AMINE *v.* BENZENYL-TOLYL-TOLYLENE-DIAMINE.

ANHYDRO-CHLORO-FORMYL-AMIDO-PHENYL MERCAPTAN *v.* CHLORO-METHENYL-AMIDO-PHENYL MERCAPTAN.

ANHYDRO-CINNAMOYL- *v.* CINNAMENYL-.

ANHYDRO-TRI-ETHYL-SULPHAMIC ACID *v.* *Tri*-ETHYL-AMINE.

ANHYDRO-FORMYL- *v.* METHENYL- or named as derivatives of formamidine.

ANHYDRO-GLYCOLYL- *v.* OXY-ETHENYL-.

ANHYDRO-LUPININE *v.* LUPININE.

ANHYDRO-NAPHTHOL SULPHONIC ACID *v.* NAPHTHOL-SULPHONIC ACID.

ANHYDRO - OXALYL - AMIDO - PHENYL MERCAPTAN $C_{14}H_8N_2S_2$ *i.e.*

$C_6H_4<\substack{N\\S}>C-C<\substack{N\\S}>C_6H_4$. [about 300°].

Formation.—1. By heating amido-phenyl mercaptan with oxalic acid and PCl_5.—2. By the action of the chloro-methenyl-amido-phenyl mercaptan on methenyl-amido-phenyl mercaptan.—3. By heating chloro-methenyl-amido-phenyl mercaptan with zinc.—4. By the action of acetyl chloride or benzoyl chloride at 150° on methenyl-amido-phenyl mercaptan.

Preparation.—1. By heating acetanilide (5 pts.) with sulphur (3 pts.) to boiling for 30 hours; yield 25 to 30 p.c.—2. By leading $(CN)_2$ gas into an alcoholic solution of amido-phenyl mercaptan.

Properties.—Sublimable. Colourless glistening plates. Nearly insoluble in all solvents; dissolves best in toluene. Bitter taste.

Reactions.—By fusing with KOH at 200° it is readily split up into amido-phenyl mercaptan and oxalic acid. On reduction with HI and P at 150° it gives aniline and ethenyl-amido-phenyl mercaptan (Hofmann, *B.* 13, 1226).

ANHYDRO - OXALYL - DI - PHENYLENE - TETRA-AMINE $C_{14}H_{10}N_4$ *i.e.*

$C_6H_4<\substack{N\\NH}>C.C<\substack{N\\NH}>C_6H_4$. [above 300°]. From *o*-di-nitro-oxanilide, Sn, and glacial HOAc (Hübner, *A.* 209, 370). Yellow needles; insol. water, CS_2, and light petroleum, m. sol. glacial HOAc, sl. sol. alcohol, ether and benzene.

Salts.—$B''2HCl\,2aq$.—$B''H_2SO_4\,2aq$.

ANHYDRO-OXALYL-DI-TOLYLENE-TETRA-AMINE

$C_6H_3(CH_3)<\substack{N\\NH}>C-C<\substack{N\\NH}>C_6H_3(CH_3)$.

[193°?]. Formed by heating oxalyl-di-tolylene-diamine to above 200° (Hinsberg, *B.* 15, 2691). Or from di-nitro-di-tolyl-oxamide, Sn, and HCl (Hübner, *A.* 209, 373).

Salts.—$B''H_2Cl_2$.—$B''(AcOH)_2$: glistening plates.—$B''_2H_2SO_4\,4aq$: needles.

ANHYDRO-PHENYL-ACETYL- *v.* PHENYL-ETHENYL-.

ANHYDRO - PHTHALYL - AMIDO-PHENYL MERCAPTAN $C_{20}H_{12}N_2S_2$ *i.e.*

$C_6H_4<\substack{N\\S}>C-C_6H_4-C<\substack{N\\S}>C_6H_4$. [112°].

Prisms or needles. Insol. water, sol. alcohol. Weak base. Prepared by heating amido-phenyl mercaptan hydrochloride with phthalyl chloride. Salts.—B'HCl: decomposed by water $(B'HCl)_2PtCl_4$: slender needles (Hofmann, *B.* 13, 1233).

ANHYDRO-PROPIONYL- *v.* PROPENYL-.

ANHYDRO-PYROGALLO-KETONE *v. Hexa*-OXY-BENZOPHENONE.

ANHYDRO-SALICYL- *v.* OXY-BENZENYL-.

ANHYDRO - SUCCINYL - AMIDO - PHENYL MERCAPTAN $C_{16}H_{12}N_2S_2$ *i.e.*

$C_6H_4<\substack{N\\S}>C.CH_2.CH_2.C<\substack{N\\S}>C_6H_4$. [137°].

Prepared by the action of succinamide on amido-phenyl mercaptan. Colourless needles. Dissolves in acids forming unstable salts. Very stable towards reducing agents. By fusing with KOH amido-phenyl mercaptan is reproduced. Salts.—B'HCl: yellow needles, decomposed by water.—$(B'HCl)_2PtCl_4$: sparingly soluble spangles.—$B'HClAuCl_3$: yellow needles (Hofmann, *B.* 13, 1231).

ANHYDRO-SULPHAMIDO- *v.* SULPHO-.

ANHYDRO-TOLUYL-DI-AMIDO-BENZENE *v.* TOLUENYL-PHENYLENE-DIAMINE.

ANHYDRO-TOLUYL-DIAMIDO-TOLUENE *v.* TOLUENYL-TOLYLENE-DIAMINE.

ANHYDRO-VALERYL- *v.* PENTENYL-.

ANIL- *v.* PHENYL-IMIDO-.

ANIL-ACETOACETIC ACID *v.* p. 19, *Reaction* 18.

ANIL-BENZYL-MALONIC ETHER $C_{20}H_{21}NO_4$ *i.e.* $C_6H_5.N:C(C_6H_5).CH(CO_2Et)_2$. [75°]. Formed by the action of *exo*-chloro-benzylidene-aniline $C_6H_5.CCl:NPh$ upon sodio-malonic ether (Just, *B.* 18, 2624). Large crystals; v. sol. alcohol and ether, insol. water. It contains a hydrogen atom readily displaceable by sodium. Heated with dilute HCl at 120° it is split up into acetophenone, aniline, ethyl chloride, and CO_2. By heating alone to about 150° it eliminates alcohol and is converted into (*Py.* 1:3:2)-oxy-phenyl-quinoline-carboxylic ether

$$C_6H_4<\begin{array}{l}C(OH):C.CO_2Et\\ \qquad\qquad\;|\\ N——CPh.\end{array}$$

Di-anil-benzyl-malonic ether $C_{33}H_{30}N_2O_4$ *i.e.* $(PhN:CPh)_2C(CO_2Et)_2$. Formed by the action of *exo*-chloro-benzylidene-aniline upon the sodium compound of mono-anil-benzyl-malonic ether (J.). Plates. By heating with dilute HCl or H_2SO_4 at 120° it is split up into benzoic acid, aniline, acetic acid, ethyl chloride, and CO_2.

ANILIDES.—Substances derived from acids by displacement of the hydroxyl by phenyl-amidogen (NHPh). They are usually described under the acids to which they belong. The term anilide may also be applied more generally to phenyl-amides and phenyl-imides.

Anilides of acids.

Formation.—1. From aniline and acid chlorides: $C_6H_5COCl + NPhH_2 = HCl + C_6H_5CO.NPhH$. 2. By boiling amides with the equivalent quantity of aniline until no more NH_3 comes off, and purifying by washing with ether (Kelbe, *B.* 16, 1199). $X.CO.NH_2 + NPhH_2 = X.CO.NPhH + NH_3$. 3. In some cases, *e.g.* formic and acetic acids, anilides are formed by simply heating aniline with the dry acid (*cf.* Tobias, *B.* 15, 2866).—4. By action of aniline upon compound ethers.—5. By the action of aniline on acid anhydrides.

Properties.—Solid crystalline substances, v. sl. sol. water.

Reactions.—Split up into acid and aniline by boiling aqueous or alcoholic KOH, by heating with HCl in a sealed tube, or by heating with conc. H_2SO_4 at 100°.

Anilides of phosphorous acid.

Tri-anilide $P(NHPh)_3$ *v.* ANILINE, *react.* 29.

Di-anilide $P(NHPh)_2(OH)$. Prepared by heating a mixture of aniline (3 pts.) and PCl_3 (1 pt.), extracting with ether and ppg. with water (Jackson a. Menke, *Am.* 6, 89). White amorphous mass; sol. alcohol and ether.

Anilides of phosphoric acid.

Tri-anilide $PO(NHPh)_3$. [208°]. From aniline and $POCl_3$ (Schiff, *A.* 101, 302; Michaelis a. Soden, *A.* 229, 335). Thin needles or six-sided trimetric plates (from alcohol). Insol. water, aqueous acids, or alkalis. Forms a hexa-bromo derivative, [258°].

Di-anilide **$PO(OH)(NHPh)_2$. [197°]. From aniline (2 pts.) and $POCl_3$ (1 pt.), the product being treated with water (M. a. S.). Insol. water. Saponified by water or acids, not by alkalis.**

Anilide of thio-phosphoric acid $PS(NHPh)_3$. [78°]. From $PSCl_3$ and aniline (Chevrier, *Z.* 1868, 539). Insol. water.

Anilide of arsenic acid $AsO(OH)_2(NHPh)$. Formed by heating aniline arsenate (Béchamp, *C. R.* 56, 1172).

Anilide of boric acid $B_2O_3NPhH_2$(?). From ethyl borate and aniline. Decomposed by water (Schiff, *A. Suppl.* 5, 209).

ANILIDO- *v.* Phenyl-amido-.

ANILINE C_6H_7N *i.e.* $C_6H_5NH_2$. *Phenylamine.* Mol. w. 93. [−8°] (Lucius, *B.* 5, 154). (185° cor.). (*Private communication from* R. J. Friswell); (183·7°) (Thorpe, *C. J.* 37, 221). S.G. $\frac{0}{4}$ 1·0379 (T.). $\frac{20}{4}$ 1·0216 (Brühl); $\frac{15}{15}$ 1·0212 (Friswell). C.E. (0°–10°) ·000866; (0°–100°) ·000925 (T.). (14°–25°) ·000818 (F.). H.F.p. −17450 (Thomsen); 2747 (Ramsay). H.F.v. −19190 (Th.). μ_β 1·6043 (B.). R_∞ 49·83 (B.). S.V. 106·37 (T.); 106·08 (R. Schiff, *B.* 19, 566); 109·1 (Ramsay). *Vapour pressure*: Ramsay a. Young (*C. J.* 47, 647, 655). S. 5 at about 15°; the S.G. of the saturated aqueous solution is $\frac{15}{15}$ 1·0023; $\frac{21}{21}$ 1·001. 100 pts. of a solution of water in aniline at 8° contain 4·6 pts. water (W. Alexejeff, *B.* 10, 709). Aniline saturated with water has S.G. $\frac{15}{15}$ 1·025 (Friswell).

Formation.—1. Discovered by Unverdorben (*P.* 8, 397) among the products of distillation of indigo, and called by him *crystalline.*—2. Rediscovered in coal tar by Runge (*P.* 31, 65, 513; 32, 331) and called by him *cyanol.*—3. Obtained by distilling indigo (from *Indigofera* '*Anil*') with potash (Fritzsche, *J. pr.* 20, 453; 27, 153; 28, 202) and then first called *aniline.*—4. Obtained from nitro-benzene by reducing with ammonium sulphide by Zinin (*J. pr.* 27, 149; 36, 98) and called by him *benzidam.* Also obtained by reducing nitro-benzene with other agents: *e.g.* Zn and HCl (Hofmann, *A.* 55, 200), ferrous acetate (Béchamp, *A. Ch.* [3] 42, 186), aqueous As_2O_3 and NaOH (Wöhler, *A.* 102, 127), zinc dust and water (Kremer, *J. pr.* 90, 255).—5. In Dippel's animal oil (Anderson, *A.* 70, 32).—6. By dry distillation of amido-benzoic acids (Hofmann a. Muspratt, *A.* 53, 221).—7. By distilling isatin with potash (Hofmann, *A.* 53, 11).—8. From di-phenyl-urea or di-phenyl-thio-urea by action of P_2O_5, zinc chloride, or HCl (Hofmann, *Pr.* 9, 274): $CO(NPhH)_2 = NPhH_2 + CO{:}NPh$.—9. Among products of distillation of peat (Vohl, *J. Ph.* [3] 36, 319).—10. By heating potassium benzene sulphonate with sodamide (Jackson a. Wing, *B.* 19, 902).—11. By the action of Br in alkaline solution upon benzamide (Hofmann, *B.* 18, 2737).—12. From phenol, and NH_3.—(*a*) Together with diphenylamine by heating phenol with zinc-chloride-ammonia, $Zn(NH_3)_2Cl_2$, at 300° to 350°. The addition of NH_4Cl diminishes the quantity of diphenylamine [illegible] improves the yield of aniline. The best yields (c. 55 p.c. aniline and 15 p.c. diphenylamine) [illegible] obtained by heating 1 pt. of phenol with 4 pt[illegible]$(NH_3)_2Cl_2$ and 4 pts. NH_4Cl under pressure [illegible]0°-340° for 20 hours.—(*b*) Together with d[illegible]ylamine by heating phenol with a mixture of NH_4Cl and ZnO; also in this case an excess of NH_4Cl diminishes the quantity of secondary amine formed. The best yields (c. 55 p.c. aniline and 20 p.c. diphenylamine) are obtained by heating 2 pts. phenol with 2 pts. ZnO and 3 pts. NH_4Cl at c. 330° for 20 hours under pressure.—(*c*) About the same results are obtained by substituting $Zn(NH_3)_2Br_2$ NH_4Br for the chlorides in (*a*) and (*b*).—(*d*) Together with diphenylamine by heating phenol with NH_4Cl and MgO. A yield of 45 p.c. aniline and 20 p.c. diphenylamine was obtained by heating 20 pts. phenol with 8·8 pts. MgO and 24 pts. NH_4Cl for 40 hrs. at 340°–350°.—(*e*) Small quantities of aniline and diphenylamine (c. 4 p.c. aniline and 15 p.c. diphenylamine) are formed by heating phenol (1 pt.) with NH_4Cl (2 pts.) alone, at 370°–400° (Merz a. Müller, *B.* 19, 2901).—13. Diphenylamine heated with conc. HCl at 320° yields small quantities of aniline and phenol.

Preparation. — By reducing nitro-benzene with iron filings in presence of a small quantity of hydrochloric or acetic acid:

$$4PhNO_2 + 4H_2O + 9Fe = 4PhNH_2 + 3Fe_3O_4.$$

Nitrobenzene (100 pts.), water (40 pts.), iron borings (25 pts.), and HClAq (9 pts.) are mixed in a cast iron vessel and the reaction started by admission of steam; more iron borings (90 pts.) are then slowly added. When the reduction is complete, lime is added, and the aniline (67 pts.) distilled over with steam. Pure aniline is best prepared from pure benzene. Aniline may be purified by conversion into its acetyl derivative, recrystallising this from water, and saponifying it with alkalis or acids. Aniline phosphate is less readily soluble in water than *o*-toluidine phosphate (Lewy, *C. J.* 46, 46).

Properties.—Colourless oil; sl. sol. water, miscible with most other menstrua. Turns red in air. Soluble in aqueous solutions of aniline hydrochloride. Its aqueous solution does not change the colour of red litmus or yellow turmeric but it changes the violet colour of dahlia to green. Congo red may also be used as an indicator (Julius, *S. C. I.* 9, 109). Aniline pps. ferrous, ferric, aluminium, and zinc, hydrates from their salts; it forms double salts with $PtCl_4$, $AuCl_3$, $HgCl_2$, $SbCl_3$, and $SnCl_4$. It gives a brownish pp. with tannin. It coagulates albumen. Potash, soda, and lime expel aniline from its salts. NH_3 is expelled when aqueous ammonium salts are boiled with aniline, but aniline is liberated when NH_3 is added to cold aqueous solutions of its salts.

Detection.—1. Very dilute aqueous solutions give a violet colour with bleaching powder; the colour is destroyed by shaking with ether (Runge). 2. Extremely dilute aqueous solutions treated successively with bleaching powder and a drop of ammonium sulphide give a rose colour (Jacquemin, *Bl.* [2] 20, 68).—3. A solution of aniline in conc. H_2SO_4 mixed with a little solid $K_2Cr_2O_7$ gives after some time a splendid blue colour; the reaction is hastened by gently warming (Beissenhirz, *A.* 87, 376).—4. If a drop of $CuSO_4Aq$ is added to an aqueous solution of aniline an apple-green crystalline pp. is formed even if the solution is very dilute; in extremely dilute solutions a green coloration is produced (Friswell).

Reactions.—1. Aniline vapour passed through a *red-hot tube* forms C, NH_3, HCN, benzene, benzonitrile (Hofmann, *Pr.* 12, 383), carbazol (Graebe, *A.* 167, 125), iso-benzidine (*v.* di-AMIDO-DIPHENYL), and quinoline (Bernthsen, *B.* 19, 420).

2. *Electric sparks* passed through liquid aniline form carbon, and a gas containing hydrogen (65 p.c.), acetylene (21 p.c.), prussic acid (9 p.c.), and nitrogen (5 p.c.) (Destrem, *C. R.* 99, 138).

3. Dilute H_2SO_4 and MnO_2 form NH_3 (Matthiessen, *Pr.* 9, 637), and a little quinone (Hofmann, *Pr.* 13, 4).

4. *Chromic acid*, CrO_3, sets fire to aniline.

5. *Chromic acid mixture* produces quinone.

6. *Potassium chlorate* and *hydrochloric acid* give tetrachloroquinone (chloranil) and trichlorophenol (Hofmann, *A.* 47, 67; 53, 28).

7. *Potassium permanganate* gives some azobenzene (Glaser, *A.* 142, 364), NH_3, and oxalic acid (Hoogewerff a. Dorp, *B.* 10, 1936; 11, 1202).

8. *Hydrogen peroxide* also produces azobenzene (Leeds, *B.* 14, 1384); which is also formed by passing aniline vapour over heated PbO (Behr a. Dorp, *B.* 6, 755).

9. *Potassium permanganate* in acid solution forms aniline black.

10. Strong *nitric acid* violently attacks aniline; picric acid is among the products. Aniline nitrate dissolved in a large quantity of H_2SO_4 produces *m*-nitro-aniline and a small quantity of *p*-nitro-aniline (Levinstein, *B.* 18, Ref. 203).

11. A mixture of aniline, *o-toluidine*, and *p-toluidine*, is converted by oxidising agents such as *nitric acid*, *mercuric chloride*, *lead nitrate*, *silver nitrate*, *arsenic acid*, and *stannic chloride* into aniline red (*v.* ROSANILINE).

12. *Nitrous acid* converts cold aqueous salts of aniline into salts of diazo-benzene (*v.* DI-AZO-COMPOUNDS); on boiling the solution nitrogen is evolved and phenol formed. Nitrous acid passed into a cold alcoholic solution of aniline produces diazo-benzene anilide.

13. When aniline is boiled with *sulphur* H_2S is evolved and di-amido-di-phenyl sulphide (thio-aniline) is formed together with other products of substitution of hydrogen by sulphur (Merz a. Weith, *B.* 3, 978).

14. *Potassium* produces NH_3 and azobenzene (Girard a. Caventou, *Bl.* [2] 28, 530).

15. *Chlorine* acts upon dry aniline with great violence, producing a black mass containing tri-chloro-aniline.

16. *Bromine* behaves like chlorine. *Bromine-water* added to solutions of salts of aniline gives a pp. of tri-bromo-aniline $C_6H_2Br_3.NH_2$ [2:4:6:1]. Bromine has no action on a solution of aniline in conc. H_2SO_4 (Morley, *C. J.* 51, 582).

17. *Iodine* dissolves in aniline forming hydriodide of *p*-iodo-aniline.

18. Hot conc. *sulphuric acid* forms *p*-amido-benzene sulphonic acid; hot fuming H_2SO_4 forms amido-benzene disulphonic acid (Buckton a. Hofmann, *C. J.* 9, 260).

19. *Sulphide of carbon* forms di-phenyl thio-urea.

20. *Sulphide of carbon* and *ammonia* produce crystals of $C_{14}H_{18}N_4S_3$ or $(PhNH_3.NH.CS)_2S$, decomposed by boiling water into CS_2, NH_3, and di-phenyl-thio-urea (Hlasiwetz a. Kachler, *A.* 166, 142).

21. *Carbon tetrabromide* forms diphenyl-*p*-amido-benzamidine hydrobromide $PhNH.C(NPh).C_6H_4.NH_2HBr$ (Bolas a. Groves, *A.* 160, 174). CCl_4 acts similarly (Hofmann, *Pr.* 9, 284).

22. *Cyanogen* forms a 'cyan-aniline' $(C_6H_5NH_2)_2C_2N_2$, [210°–220°] (Hofmann, *A.* 66, 129; 73, 180; *B.* 3, 763). Insol. water, sl. sol. alcohol. Boiling acids decompose it into phenyl-oxamide, di-phenyl-oxamide, oxamide, aniline, and NH_3. Nitrous acid produces a base $C_{14}H_{15}N_5O_5$ (Senf, *J. pr.* [2] 31, 543). **Salts of Cyananiline:** $B''2HCl$. — $B''H_2PtCl_6$. — $B''2HAuCl_4$.—$B''2HBr$.—$B''2HNO_3$.

23. *Chloride of sulphur* diluted with CS_2 forms tri-phenyl-guanidine (di-phenyl thio-urea being first formed, Claus a. Krall, *B.* 3, 527; 4, 99).

24. Heated with *persulphocyanic acid* it gives phenyl-thio-biuret.

25. *Carbonyl chloride*, $COCl_2$, gives di-phenyl-urea.

26. *Gaseous cyanogen chloride* forms di-phenyl-guanidine (melaniline); in presence of water phenyl-urea is formed (Hofmann, *A.* 70, 130). CyCl passed into an ethereal solution forms phenyl cyanamide (cyananilide, Cahours a. Cloëz, *C. R.* 38, 354). *Solid chloride of cyanogen* forms 'chlorocyananilide' $C_{15}H_{12}ClN_5$ (Laurent, *A.* 60, 273).

27. *Cyanic acid* forms phenyl-urea.

28. When treated in ethereal solution with perchloromethylmercaptan $CCl_3.SCl$ it yields the compound $CCl_3.S.NHC_6H_5$. If the ethereal solution of the latter body is mixed with alcoholic KOH or NH_3 it splits off HCl and a crystalline compound separates which has the probable constitution $CCl_2.S.NC_6H_5$, (Rathke, *B.* 19, 395).

29. *Phosphorus trichloride* acts vigorously, producing 'phosphaniline hydrochloride' $PCl_33C_6H_7N$ (Tait, *Z.* [2] i., 649). It is perhaps the anilide of phosphorous acid $P(NPhH)_33HCl$. $PtCl_2PCl_3$ forms $(PhNH)_3PPtCl_2NH_2PhHCl$ whence water produces $(PhNH)_3PPtCl(OH)$ (Quesneville, *Monit. scient.* [3] 6, 659). PCl_32PtCl_2, alcohol, and aniline produce $P(OEt)_3PtCl_2(C_6H_7N)_2$ and $P_2(OEt)_6PtCl_2(C_6H_7N)_2$ (Cochin, *C. R.* 86, 1402).

30. *Phosphorus oxychloride* produces very unstable anilide of phosphoric acid, $PO(NPhH)_3$ (Schiff, *A.* 101, 302; Michaelis a. Soden, *A.* 229, 335).

31. Aniline, *isobutyric acid*, and $ZnCl_2$ give iso-butyric anilide (Bardwell, *Am.* 7, 116).

32. *Aniline-zinc-chloride* and *isoamyl alcohol* give amido-phenyl-isopentane.

33. *Chloroform* at 190° forms di-phenyl-formamidine, CH(NPh)(NPhH).

34. *Chlorides, bromides*, and *iodides* of alcoholic or acid radicles act upon aniline as they do upon other primary amines (*v.* AMINES). Alkyls may also be introduced by heating aniline hydrochloride or, better, hydrobromide with alcohols (Staedel a. Reinhardt, *B.* 16, 29). Methyl-aniline hydrochloride is converted by heat into toluidine hydrochloride (Hofmann, *B.* 5, 720); similarly aniline hydrochloride heated with MeOH at 290° forms $C_6H_4MeNMe_2$.

$C_6H_3Me_2NMe_2$, $C_6H_2Me_3NMe_2$, $C_6HMe_4NMe_2$, and C_6Me_6 (Hofmann a. Martius, *B.* 4, 742).

35. *Aldehydes* act upon aniline with elimination of water: *e.g.*

$$CH_3.CHO + 2H_2NPh = H_2O + CH_3.CH(NHPh)_2$$
$$CH_3.CHO + H_2NPh = H_2O + CH_3.CH{:}NPh$$

(Schiff, *A. Suppl.* 3, 344). The last formula ought perhaps to be written $(CH_3.CH)_2(NPh)_2$ (*v.* METHYLENE-ANILINE; ETHYLIDENE-ANILINE; CHLORO-ETHYLIDENE-ANILINE, &c.). Aniline acts similarly upon *glucose*, *levulose*, and *galactose*, forming $C_6H_7(OH)_5(NPh)$ (Schiff, *A.* 154, 30; Sorokin, *B.* 19, 513).

36. *Aniline sulphite* gives with an ethereal solution of *aldehyde* prisms of $PhNH_2C_2H_4OSO_2$ or $PhNH.SO_2.CHMe.OH$ (Schiff, *A.* 140, 127; 210, 129).

37. *Chloral* and aqueous SO_2 produce unstable crystals of $PhNH_3SO_3.CH(OH).CCl_3$ (Schiff, *A.* 210, 129).

38. *Acetone* and aqueous SO_2 form an unstable compound, $PhNH_2C_3H_6O SO_2$ which is perhaps $Me_2C(OH).SO_2.NHPh$ (S.).

39. *Acetone* (1 mol.) and P_2O_5 two days at 180° form $Me_2C{:}NPh$, (200°-220°) (Engler a. Heine, *B.* 6, 642; *cf.* Pauly, *A.* 187, 222).

40. Aniline hydrochloride heated with *acetone* or *mesityl oxide* at 190° forms some (*Py.* 1, 3)-di-methyl-quinoline (Engler a. Riehm, *B.* 18, 2245, 3296).

41. A mixture of *aldehyde* and *acetone* at 100° give (*Py.* 1, 3)-di-methyl-quinoline (Beyer, *J. pr.* [2] 33, 393).

42. *Paraldehyde* and conc. HCl at 100° form (*Py.* 3)-methyl-quinoline (quinaldine, Doebner a. von Miller, *B.* 16, 2464).

43. Aniline (1 pt.) distilled with *glycerin* (1 pt.) and H_2SO_4 (2 pts.) forms *quinoline* (Königs, *B.* 13, 911). Quinoline is also formed by distilling acroleïn-aniline, or by heating aniline with *glycerin*, *nitrobenzene*, and H_2SO_4 (Skraup, *M.* 2, 141). *Aniline-zinc-chloride* heated with glycerin forms skatole (Fischer a. German, *B.* 16, 710).

44. *Aceto-acetic ether* at 120°-150° gives aceto-acetic anilide $CH_3.CO.CH_2.CO.NPhH$ (*cf.* ACETO-ACETIC ACID, *reaction* 18), [85°]. Sl. sol. water and NH_3Aq, v. sol. NaOHAq and acids. Distilled with aniline it gives *s*-di-phenyl urea. Boiling potash produces aniline, acetone, and acetic acid. Fe_2Cl_6 colours its aqueous solution violet. Br produces $CH_3.CO.CHBr.CONPhH$, [138°]. Conc. H_2SO_4 forms (*Py.* 3, 1)-oxy-methyl-quinoline. Nitrous acid forms $CH_3.CO.C(NOH).CO.NPhH$, [100°] (Knorr, *A.* 236, 75).

45. *Acetophenone cyanhydrin* gives rise to $C_6H_5.CMe(NHPh)CN$ (Jacoby, *B.* 19, 1515).

46. An alcoholic solution of *quinone* produces $C_6H_2(NHPh)_2O_2$ and hydroquinone. The former dissolves in conc. H_2SO_4 forming a crimson solution.

47. *Tetrachloro-quinone* (chloranil) produces, similarly, $C_6Cl_2(NHPh)_2O_2$ (Hofmann, *Pr.* 13, 4; Hesse, *A.* 114, 292; Knapp a. Schultz, *A.* 210, 164).

48. *Aniline* mixed with an *anilide* and PCl_3 produces a phenyl-amidine: *e.g.*

$$3PhNH_2 + 3CH_3.CO.NHPh + 2PCl_3 =$$
$$3CH_3.C(NPh).NHPh + P_2O_3 + 6HCl$$ (Hofmann, *Z.* 1866, 161).

49. *Aniline hydrochloride* and *acetonitrile* at 170° produce phenyl-acetamidine:

$$CH_3CN + H_2NPh = CH_3C(NPh).NH_2.$$

50. With *benzo-trichloride*, $PhCCl_3$ (1 mol.), aniline (2 mols.) on warming acts violently forming the hydrochloride of di-phenyl-benzamidine, $C_6H_5C(NPh)(NPhH)2HCl$: aniline in glacial acetic acid, $ZnCl_2$ and $PhCCl_3$ give, chiefly, the same body.

51. But aniline hydrochloride (40 pts.), *nitrobenzene* (45 pts.), *benzo-trichloride* (40 pts.), and *iron filings* at 180° form the chloride of di-amido-tri-phenyl-carbinol (*q. v.*).

52. Aniline (2 mol.) boiled with *chloro-acetic acid* (1 mol.) and *water* produces phenyl-amido-acetic acid and phenyl-imido-di-acetic acid; the aniline salt of the latter, $PhN(CH_2.CO_2NH_3Ph)_2$, crystallises in needles, [99°] (P. Meyer, *B.* 14, 1325).

53. An alcoholic solution of aniline, *chloro-acetic acid*, and *ammonium sulphocyanide* at 100° deposits crystals of phenyl-thio-hydantoïc acid $NH_2.C(NPh).S.CH_2.CO_2H$, [148°-152°]. This acid is decomposed by boiling with dilute (20 p.c.) H_2SO_4 into phenyl-urea and thio-glycollic acid (Jaeger, *J. pr.* [2] 16, 17; Claesson, *B.* 14, 732; Liebermann, *A.* 207, 129).

54. *Acetamidoxim hydrochloride* is converted by heating with aniline into acetanilidoxim, $CH_3.C(NOH).NHPh$, [121°] (Nordmann, *B.* 17, 2753).

55. *Zincethide* forms zincanilide $Zn(NHPh)_2$, which is decomposed by water into $Zn(OH)_2$ and aniline (Frankland, *Pr.* 8, 504).

Salts.—(Beamer a. Clarke, *Am.* 1, 151; *B.* 12, 1066; Hjortdahl, *Z. K.* 6, 471). — $B'HCl$. [192°] (Pinner, *B.* 14, 1083). Needles or plates, v. sol. water and alcohol; may be sublimed.— $B'_2H_2PtCl_6$: yellow needles. — $B'_2H_2SnCl_6$: monoclinic. — $B'_2H_2CuCl_4$. — $B'HBr$: trimetric, $a{:}b{:}c = {\cdot}723{:}1{:}{\cdot}818$. — $B'HCdBr_3$: trimetric. — $B'HI$.—$B'HBiI_4$ (Kraut, *A.* 210, 323).—$B'HF$: pearly scales, sol. water and boiling alcohol.— $B'HClO_3$: long white prisms, sol. alcohol and ether, m. sol. water; explodes at 75°.—$B'HClO_4$. —$B'HIO_3$. S.G. $^{\underline{13}}$ 1·48. Explodes at 125°-130°. —$B'HCNHg(CN)_2$. [88°]. White needles or tables (Claus a. Merck, *B.* 16, 2737). — $B'_4H_4FeCy_6$: small micaceous crystals, v. sol. water, insol. alcohol and ether (Eisenberg, *A.* 205, 267). — $B'_2H_4FeCy_6$. — $B'_3H_3CoCy_6$. — $B'_2H_2PtCy_4$: triclinic (Scholtz, *M.* 1, 904). — $B'_2H_3PO_4$: laminæ, v. sol. water, ether, and hot alcohol (Nicholson, *A.* 59, 213; Levy, *B.* 19, 1717). — $B'_3H_3PO_4$. — $B'HPO_3$. — $B'_2H_4P_2O_7$. — $B'_2H_2SO_4$: m. sol. water, sl. sol. alcohol, insol. ether. Does not form an alum with aluminium sulphate (W[illegible] *C. N.* 38, 1).—$B'H_2SO_4$: large plates; converted by water into the neutral sulphate (Wellington a. Tollens, *B.* 18, 3313). — $B'_2H_2S_2O_6$ (Malczewsky, *J. R.* 11, 364). — $B'_6(H_2SO_4)_3HI_5$ (Jörgensen, *J. pr.* [2] 14, 384).— $B'HNO_3$. — *Chloro-acetate.* [88°]. — *Di-chloro-acetate.* [122°]. — *Tri-chloro-acetate.* [145°].—*Oxalate* $B'_2H_2C_2O_4$: triclinic columns, v. sol. water, sl. sol. alcohol, insol. ether. — *Phenate*, $B'HOPh$. [30°]. (181°) (D.). (125°) (D. a. S.). Crystals resembling naphthalene (from alcohol or light petroleum) (Dyson, *C. J.* 43, 466). Formed by boiling equivalent quantities of phenol and aniline together Dale a. Schorlemmer, *C. J.* 43, 186). —***Phthalate***, [146°]: needles.—(β)-***Naphtholate***, [82·4°]: crystalline powder (from light petroleum) (Dyson, *C. J.* 43, 469). Other salts of aniline are described under the various acids.

Combinations.—(Schiff, *C. R.* 56, 268, 1095; Vohl, *Ar. Ph.* [2] 148, 201; Leeds, *J.* 1882, 500). —$B'_3(SiF_4)_2$: minute needles, insol. benzene or petroleum-spirit; may be sublimed; converted by water or alcohol into aniline silicofluoride (Jackson a. Comey, *B.* 18, 3195). — $B'_4Ag_2SO_4$ 2aq: hair-like crystals (Mixter, *Am.* 1, 239). — B'_2ZnSO_4. — B'_2ZnCl_2. — B'_2ZnBr_2.— B'_2ZnI_2.—$C_6H_5NH.HgCl$: amorphous pp. got by mixing hot alcoholic solutions of aniline and $HgCl_2$ (Forster, *A.* 175, 30).—B'_2HgCl_2: needles, got by mixing cold alcoholic solutions of aniline and $HgCl_2$.—B'_2HgBr_2 [112°] (Klein, *B.* 13, 835). — B'_2HgI_2. [60°]. Decomposed by alcohol.— $B'_2Hg(NO_3)_2$: pp., converted by hot water into $C_6H_5NH.HgNO_3$ ½aq and $(PhN)_2Hg_3(NO_3)_2$ 2aq. —B'_2CaCl_2. — B'_2CdCl_2. — B'_2CdBr_2. — B'_2CdI_2. — $B'_2Cd(NO_3)_2$. — B'_6TiCl_4. — B'_2SnI_2. — B'_3SbCl_5. — $B'_2UrO_2Cl_2$. — B'_2MnCl_2.—B'_2MnBr_2.—B'_2MnI_2.— B'_2FeCl_2.—B'_2SnCl_4.—B'_3AsCl_3. [c. 90°]. (c. 208°). — B'_3SbCl_3. [80°]. — B'_3BiCl_3. — $B'BiOCl$. — B'_2CoCl_2 2EtOH: red leaflets, prepared by adding aniline (2 mols.) to an alcoholic solution of $CoCl_2$ (1 mol.); at 100° it becomes blue B'_2CoCl_2 (Lippmann a. Vortmann, *B.* 12, 79). — B'_2NiCl_2 2EtOH: small green needles, similarly prepared; at 100° it becomes yellowish green B'_2NiCl_2 (L. a. V.).—B'_2CuCl_2 (Destrem, *Bl.* 30, 482).—B'_2CuSO_4.—B'_2PtCl_2 (Gordon, *B.* 3, 176; Cochin, *Bl.* 31, 499). — $B'PtCl_2C_2H_4HCl$. — $B'PtCl_2C_2H_4$ (Griess a. Martius, *A.* 120, 326).

Acetyl derivative C_8H_9NO *i.e.* $C_6H_5NH.C_2H_3O$. *Acetanilide.* Mol. w. 135. [114°]. (295°). S. ·34 at 14°; 6·59 at 102·5° (Friswell, *private com.*). V.D. 4·8 (calc. 4·7).

Formation. — 1. From aniline and AcCl (Gerhardt, *A.* 87, 164).—2. By boiling aniline with glacial acetic acid (Greville Williams, *C. J.* 17, 106; *v.* also CHEMICAL CHANGE).—3. By heating aniline with acetamide (Kelbe, *B.* 16, 1199).—4. From acetophenone-oxim and H_2SO_4 at 100° (Beckmann, *B.* 20, 1507).

Properties.—Laminæ (from water); v. sol. alcohol, ether, and benzene. A saturated aqueous solution boils at 102·5° (Friswell).

Reactions. — 1. Passed through a *red-hot tube* it forms di-phenyl-urea, aniline, benzene, and CNH (Nietzki, *B.* 10, 476).—2. $ZnCl_2$ at 260° gives flavaniline $C_{16}H_{14}N_2$. — 3. PCl_5 forms $CH_3.CCl_2NHPh$ which readily splits up into HCl and $CH_3.CCl:NPh$. The latter is converted by water into HCl and acetanilide, and by aniline into di-phenyl-acetamidine, $CH_3.C(NHPh):NPh$. $CH_3.CCl:NPh$ changes a little above its melting point [50°] into the hydrochloride of $CH_3.C(NPh).CH_2.CCl:NPh$, [117°] which at 160° changes to the hydrochloride of amorphous $C_{16}H_{14}N_2$ (Wallach, *A.* 184, 86; *cf.* Michael, *J. pr.* [2] 35, 207).—4. P_2S_5 forms thio-acetanilide (Hofmann a. Simpson, *B.* 11, 339; Jacobsen, *B.* 19, 1071; *v.* THIOACETIC ACID).—5. Heating with *sulphur* produces oxalyl-amido-phenyl mercaptan,  $C_6H_4{<}\genfrac{}{}{0pt}{}{N}{S}{>}C.C{<}\genfrac{}{}{0pt}{}{N}{S}{>}C_6H_4$, and some ethenyl-amido-phenyl mercaptan (Hofmann, *B.* 13, 1226). — 6. Dry NaOEt at 170° gives ethyl-aniline AcNHPh + NaOEt = EtNHPh + NaOAc. 7. *Nitrous acid* passed into a solution of acetanilide in glacial HOAc forms an unstable nitrosamine, PhNAc.NO, [41°] (O. Fischer, *B.* 9, 463). — 8. *Nitric acid* converts acetanilide dissolved in 4 pts. of H_2SO_4 chiefly into *p*-nitro-acetanilide, some *o*- being formed. If the acetanilide is dissolved in 20 pts. H_2SO_4 a small quantity of the *m*-compound appears (Nölting a. Collin, *B.* 17, 261).

Sodium acetanilide C_6H_5NAcNa (Runge, *Z.* [2] 6, 119). Formed by distilling off the alcohol from an alcoholic solution of equivalent quantities of acetanilide and sodium ethylate (Seifert, *B.* 18, 1358). Crystalline powder. Absorbs CO_2 in the cold, becoming sodium acetyl-phenyl-carbamate, $C_6H_5NAc.CO_2Na$.

Mercury acetanilide $(C_6H_5NAc)_2Hg$. [215°]. Formed by melting acetanilide with HgO (Oppenheim a. Pfaff, *B.* 7, 624).

Hydrochloride $(C_6H_5.NHAc)_2HCl$ crystallises in needles, decomposed by water. By heating for half-an-hour at 250° it splits off acetic acid and yields the hydrochloride of di-phenyl-acet-amidine $CH_3.C(NPh).NHPh$. By 6 hours' heating at 280° it gives flavaniline. At a still higher temperature quinoline bases are formed in small quantity (Nölting a. Weingärtner, *B.* 18, 1340).

v-Chloro-acetanilide $C_6H_5.NClAc$. *Acetyl-phenyl-chloro-amide.* [172°]. Prepared by adding a conc. solution of bleaching powder to a conc. aqueous solution of acetanilide containing excess of acetic acid, as long as a pp. is formed. Colourless needles. Scarcely soluble in water. Crystallises well from very dilute acetic acid. Heated to 172° it suddenly changes, with explosive violence, to the isomeric *p*-chloro-acetanilide. This change is also produced by cold conc. HCl with a violent reaction. It dissolves in warm absolute alcohol at first unaltered, but after a few moments a violent reaction sets in and the above change takes place. Alkalis and amine bases replace the Cl by H. It converts aceto-acetic ether into chloro-aceto-acetic ether. Not attacked by boiling water (Bender, *B.* 19, 2272).

Diacetyl derivative $C_{10}H_{11}NO_2$ *i.e.* $C_6H_5NAc_2$. [111°]. *Diacetanilide.* From phenyl thiocarbimide and HOAc at 140° (Hofmann, *B.* 3, 770): $PhNCS + 2HOAc = PhNAc_2 + CO_2 + H_2S$. Plates. On distillation it gives acetanilide (Gumpert, *J. pr.* [2] 32, 293).

Benzoyl derivative C_6H_5NHBz. [159°].

Formation.—1. From aniline and BzCl (Gerhardt, *A. Ch.* [3] 37, 327).—2. By the action of phenyl cyanate upon benzene in presence of $AlCl_3$; the reaction probably being:

(*a*) $PhN.CO + HCl = PhNH.COCl$.

(*b*) $PhNH.COCl + C_6H_6 = PhNH.COC_6H_5 + HCl$

(Leuckart, *B.* 18, 873). 3. From benzophenone oxim and H_2SO_4 at 100° (Beckmann, *B.* 20, 1507)

Properties.—Volatile plates; insol. water.

Reactions.—1. PCl_5 forms $PhNH.CCl_2Ph$ and then PhN:CClPh, [40°] (Wallach, *A.* 184, 79).—2. Boiling with *sulphur* produces benzenyl-amido-phenyl mercaptan.

Oxim $C_{13}H_{12}N_2O$ *i.e.* $C_6H_5.C(NOH)NHC_6H_5$ *Benz-anilidoxim.* [136°] Obtained by heating thiobenzanilide with hydroxylamine hydrochloride and Na_2CO_3 in alcoholic solution for about an hour (Müller, *B.* 19, 1669). Slender needles. Sol. hot water, alcohol, ether, chloroform, and benzene, sl. sol. ligroïn. Dissolves both in acids and alkalis. Salts.—B'HCl: sol. alcohol.—$B'_2H_2Cl_2PtCl_4$×. *Ethyl ether* $C_6H_5.C(NHPh):NOEt$. [56°]; white pp. *Benzoyl derivative* $C_6H_5.C(NHPh)NOBz$. [116°]; white glistening needles; sol. alcohol, ether, and benzene, insol. water and ligroïn.

Di-benzoyl derivative $NPhBz_2$. [136°]. From benzanilide and BzCl (Gerhardt a. Chiozza, *C. R.* 37, 90).

Preparation.—Benzanilide (18 g.) is heated with BzCl (14 g.) for 3 hours.

Properties.—Needles (from alcohol). With dilute HCl at 120° it gives aniline and benzoic acid (Higgin, *C. J.* 41, 132).

Di-benzoyl derivative $C_6H_5NBz_2$. [160°] (isomeric with preceding?). From benzoic acid (13 g. and phenyl thiocarbimide (6 g.) at 220° for 6 hours (Losanitch, *B.* 6, 176; Higgin, *C. J.* 41, 133): $PhN:CS + 2HOBz = PhNBz_2 + CO_2 + H_2S$.

Properties.—Plates (from alcohol). With dilute HCl at 120° it gives aniline and benzoic acid.

ANILINE BLACK $C_{30}H_{25}N_5$. *Nigraniline.* Formed by mixing aniline, a chlorate (of K, Na, or Ba) and a metallic salt (of Cu, Fe, V, Mn, or Ce) (Lightfoot, *C. N.* 11, 65; Lauth, *Bl.* [2] 2, 416; Higgin, *Bl.* [2] 7, 93; Guyard, *Bl.* [2] 25, 58; Rosenstiehl, *Bl.* [2] 25, 356; *C. R.* 81, 1257; Kruis, *D. P. J.* 222, 347; Goppelsröder, *C. R.* 82, 331, 1392; Coquillion, *C. R.* 81, 408; Glenk, *D. P. J.* 248, 234). The quantity of metallic salt may be small; ammonium vanadate added to a solution of aniline hydrochloride (6 pts.) and $NaClO_3$ or $KClO_3$ (4 pts.) in water (100 pts.) converts 100,000 times its weight of aniline into black. An aniline black is formed at the positive pole when a solution of an aniline salt is electrolysed. Aniline black is purified by washing with water, alcohol, ether, and benzene. It is the hydrochloride of a base, $C_{30}H_{25}N_5 2HCl$; and can be reduced by tin and HCl, or by HI and P, to *p*-phenylene-diamine and *p*-diamido-diphenylamine $NH_2.C_6H_4.NH.C_6H_4.NH_2$ (Nietzki, *B.* 11, 1093). Electrolytic aniline black appears to be $C_{24}H_{20}N_4 2HCl$ (Goppelsröder).

ANILINE CARBOXYLIC ACID *v.* PHENYL-CARBAMIC ACID.

ANILINE DYES *v.* ROSANILINE, MAUVEÏNE, CHRYSANILINE &c.

ANILOTIC ACID is Nitro-salicylic acid *v.* NITRO-OXY-BENZOIC ACID.

ANILOXALBENZAMIC ACID *v.* PHENYL-OXAMIDO-BENZOIC ACID.

ANIL-PYRUVIC ACID $C_9H_9NO_2$ *i.e.* $CH_3.C(NPh).CO_2H$. [122°]. Formed by the action of aniline on pyruvic acid (Böttinger, *B.* 16, 1924; *A.* 188, 336). Crystals, v. sol. water. In contact with water it condenses to aniluvitonic or (*Py.* 3, 1)-methyl-quinoline carboxylic acid (*q.v.*). On bromination it yields tribromanil-dibromopyruvic acid. Salt.—BaA'_2: v. e. sol. water.

ANIL-UVITONIC ACID *v.* (*Py.* 3)-METHYL QUINOLINE (*Py.* 1)-carboxylic acid.

ANISAMIDE. Amide of methyl-*p*-oxy-BENZOIC ACID.

ANISANILIDE. Anilide of methyl-*p*-oxy-BENZOIC ACID.

ANIS-BENZ-ANIS-HYDROXYLAMINE *v.* HYDROXYLAMINE.

ANIS-BENZ-HYDROXAMIC ACID *v.* HYDROXYLAMINE.

DI-ANIS-BENZ-HYDROXYLAMINE *v.* HYDROXYLAMINE.

ANISE, OIL OF. The essential oil obtained by distilling the seeds of *Pimpinella anisum* or *Illicium anisatum* with water. It contains anethol (*q.v.*). If the oil is heated with dilute HNO_3 (S.G. 1·2) and the resulting heavy oil shaken with warm $NaHSO_3Aq$, so-called anisoïc or thianisoïc acid $C_{10}H_{14}SO_4$ [below 100°] is formed (Limpricht a. Ritter, *A.* 97, 364; Staedeler a. Wächter, *A.* 116, 169). It is a very soluble crystalline mass. $NH_4A'aq$.—$NaA'aq$.—$MgA'_2 5aq$.—$CaA'_2 2aq$.—$BaA'_2 3aq$.—AgA'.

ANISE CAMPHOR. A name for anethol (*q.v.*).

ANISHYDRAMIDE $C_{24}H_{24}N_2O_3$ *i.e.* $(MeO.C_6H_4.CH)_3N_2$. *Tri-methyl-tri-oxy-hydrobenzamide.* [c. 120°]. Formed by action of conc. NH_3Aq upon *p*-methoxy-benzoic (anisic) aldehyde. Prisms, insol. water, sol. boiling alcohol, ether, or conc. HClAq (Cahours, *A. Ch.* [3] 14, 487; Bertagnini, *A.* 88, 128). Changes at 170° into Anisin, a basic isomeride which forms salts: B'HCl aq.—$B'_2H_2PtCl_6$.

ANIS-HYDROXAMIC ACID *v.* HYDROXYLAMINE.

ANISIC ACID *v.* *p-Methyl*-OXY-BENZOIC ACID.

ANISIC ALDEHYDE *v.* *p-Methyl*-OXY-BENZOIC ALDEHYDE.

ANISIC ALCOHOL *v.* *p-Methyl*-OXY-BENZYL ALCOHOL.

ANISIDINE *v.* Methyl derivative of AMIDO-PHENOL.

ANISIL $C_{16}H_{14}O_4$ *i.e.* $C_6H_4(OMe)—CO—CO—C_6H_4(OMe)$. [133°]. Prepared by oxidation of anisoïn with Fehling's solution (Bösler, *B.* 14, 327). Yellow needles. Distils undecomposed. Sol. hot, sl. sol. cold, alcohol, insol. water. On boiling with alcoholic KOH it gives anisilic acid.

ANISILIC ACID $C_{16}H_{16}O_5$ *i.e.* $(MeO.C_6H_4)_2C(OH).CO_2H$. [164°]. Prepared by boiling anisil with alcoholic KOH (Bösler, *B.* 14, 328). Slender white needles. Sol. alcohol, sl. sol. water. Dissolves in strong H_2SO_4 with a violet colour. On oxidation with CrO_3 it gives di-methoxy-benzophenone.

ANISIN *v.* ANISHYDRAMIDE.

ANISOÏN $C_{16}H_{16}O_4$ *i.e.* $MeO.C_6H_4CH(OH).CO.C_6H_4.OMe$. *Di-methyl-tri-oxy-phenyl-benzyl-ketone.* [113°]. Prepared by boiling *p*-methoxy-benzoic (anisic) aldehyde with alcoholic KOH (yield 60 p.c.; Bösler, *B.* 14, 326), or KCy (Rossel, *Z.* [2] 5, 562). Needles; v. sl. sol. water, sl. sol. cold alcohol and ether. Strong H_2SO_4 dissolves it with red colour, rapidly changing to pale green, and on heating, to yellow and then purple. See also HYDRO-ANISOÏN.

ANISOÏC ACID *v.* ANETHOL.

ANISOL *v.* *Methyl*-PHENOL.

ANISOL-ISATIN *v.* *Di-methyl-di*-OXY-DI-PHENYL-OXINDOLE.

ANISOL-PHTHALIC ACID *v.* *Methyl*-OXY-BENZOPHENONE CARBOXYLIC ACID.

ANISONITRILE *v.* *Nitrile of Methyl-p*-OXY-BENZOIC ACID.

ANISO-DIUREÏDE *v.* *Methyl*-OXY-BENZENYL-DI-UREA.

ANISURIC ACID $C_{10}H_{11}NO_4$ *i.e.* $MeO.C_6H_4.CO.NH.CH_2.CO_2H$. *Methyl-oxy-benzoyl-glycocoll.*—From silver amido-acetate and methyl-*p*-oxy-benzoyl chloride. Also secreted when methyl-*p*-oxy-benzoic (anisic) acid is taken into the stomach. Laminæ. Split up by acids into glycocoll and anisic acid.

Salts: CaA'_2 3aq.—AgA' (Cahours, *A.* 103, 90; 109, 32; Graebe a. Schultzen, *A.* 142, 348).

ANISYL. This name is usually given to the radicle methyl-*p*-oxy-phenyl, $CH_3O.C_6H_4$, but sometimes also to methyl-*p*-oxy-benzoyl, $CH_3O.C_6H_4.CO$, which could more appropriately be called anisoyl.

ANISYL BROMIDE *v.* *p*-BROMO-PHENOL, *Methyl-ether* and *Methyl*-OXY-BENZOYL BROMIDE.

ANISYL CARBAMIDE *v.* *Methyl-p*-OXY-PHENYL-UREA.

ANISYL CHLORIDE *v.* *p*-CHLORO-PHENOL, *Methyl-ether* and *Methyl*-OXY-BENZOYL CHLORIDE.

ANISYL METHYL KETONE *v.* *Methyl*-OXY-ACETOPHENONE.

ANISYL-THIO-UREA *v.* *Methyl*-OXY-PHENYL-THIO-UREA.

ANISYL-UREA *v.* *Methyl*-OXY-PHENYL-UREA.

ANOL $C_9H_{10}O$ *i.e.* $HO.C_6H_4.CH:CH.CH_3$. [92·5°]. (c. 250°). Formed by heating anethol with KOH. Shining laminæ (from alcohol, ether, and chloroform) sol. KOHAq and reppd. by acids (Ladenburg, *B.* 2, 371).

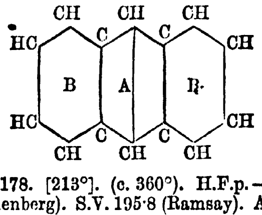
ANTHEMENE $C_{18}H_{36}$. [64°]. (440°). S.G. $\frac{15}{15}$ ·942. V.D. 127 (calc. 131). S. (alcohol) ·033 at 25°. Extracted from flowers of chamomile (*Anthemis nobilis*) by light petroleum (Naudin, *Bl.* [2] 41, 483). Minute needles, insol. water, sol. ether, petroleum, CS_2, chloroform, and hot alcohol.

ANTHEMOL $C_{10}H_{16}O$. (214°). Occurs in oil of chamomile (*Anthemis nobilis*). Thick liquid with camphor-like smell (Koebig, *A.* 195, 104). Boiling dilute HNO_3 produces terephthalic and *p*-toluic acids. *Acetyl derivative* $C_{10}H_{15}OAc$. (235°).

ANTHOCYANIN. Blue colouring-matter of flowers *v.* PIGMENTS.

ANTHOXANTHIN. Yellow colouring matter of flowers, *v.* PIGMENTS.

ANTHRACENE $C_{14}H_{10}$ *i.e.*



Mol. w. 178. [213°]. (c. 360°). H.F.p. −115,000 (v. Rechenberg). S.V. 195·8 (Ramsay). Alcoholic solutions containing less than ·03 p.c. exhibit absorption bands in the ultra-violet part of the spectrum (Hartley, *C. J.* 39, 162). S. (ether) 1·17 at 15°; S. (HOAc) ·44 at 15°. S. (benzene) 1·7 at 15°. S. (alcohol) ·08 at 16°; (dilute alcohol, S.G. ·84) ·46 at 15° (Versmann, *J.* 1874, 423; Becchi, *B.* 12, 1978).

Occurrence.—In coal tar (Dumas a. Laurent, *A. Ch.* [2] 50, 187). From crude anthracene the following bodies may be extracted by acetic ether:—(*a*) Soluble in cold alcohol: carbazol, phenanthrene, fluorene, and a hydrocarbon [130°]. Carbazol is insoluble in CS_2, the others dissolve, but can be separated by their picrates. (*b*) Soluble in cold benzene: synanthrene and two hydrocarbons [104°] and [97°].—(*c*) Soluble in hot benzene: anthracene (insoluble in dilute alcohol) and pseudophenanthrene (soluble in dilute alcohol).—(*d*) Insoluble in benzene: carbazol (Zeidler, *A.* 191, 302).

Formation.—1. By passing through red-hot tubes a mixture of ethylene with benzene, diphenyl, or chrysene; or a mixture of benzene and styrene (Berthelot, *Bl.* [2] 7, 223; 8, 231; 9, 295) or benzene and petroleum (Letny, *B.* 10, 412; 11, 1210), or benzene and oil of turpentine (Schultz, *B.* 7, 113).—2. By passing benzyl-toluene, $Ph.CH_2.C_6H_4.CH_3$, through a red-hot tube, or over heated litharge (Behr a. Dorp, *B.* 6, 754; *A.* 169, 216).—3. By action of $AlCl_3$ on a mixture of benzene and *s*-tetra-bromo-ethane (Anschütz a. Eltzbacher, *B.* 16, 623).—4. By action of sodium on *o*-bromo-benzyl bromide (Jackson a. White, *Am.* 2, 392; *B.* 12, 1965).—5. By heating benzyl ethyl oxide, $PhCH_2.O.Et$, with P_2O_5 (J. Schulze, *J. pr.* [2] 27, 518).—6. By action of $CHCl_3$ or CH_2Cl_2 on benzene in presence of $AlCl_3$ (Friedel, Crafts, a. Vincent, *Bl.* [2] 40, 97; 41, 325).—7. By heating benzyl chloride with water at 200° and distilling the product (Limpricht, *A.* 139, 303; Zincke, *B.* 7, 278).—8. By heating a mixture of alizarin with zinc dust at low red heat (Graebe a. Liebermann, *A. Suppl.* 7, 297).—9. By distilling *o*-tolyl phenyl ketone with zinc dust (Behr a. Dorp, *B.* 7, 17).—10. Together with toluene by the action of $AlCl_3$ on benzyl chloride (Perkin a. Hodgkinson, *C. J.* 37, 726).—11. By distilling benzyl-phenol with P_2O_5 (Paterno a. Fileti, *B.* 6, 1202).—12. By heating *o*-benzoyl-benzoic acid with zinc dust (Gresly, *A.* 234, 238).

Properties.—Four- or six-sided monoclinic white tables with blue fluorescence. Insol. water, sl. sol. alcohol, ether, benzene, glacial HOAc, chloroform, CS_2, and light petroleum. Changed in sunlight into para-anthracene (paraphotene) [244°], which is insoluble in most menstrua, but is reconverted into anthracene by fusion.

Estimation.—Anthracene (1 g.) is dissolved in boiling glacial HOAc (45 c.c.), filtered if necessary, and a solution of CrO_3 (10 g.) in glacial HOAc (5 c.c.) diluted with water (5 c.c.) is slowly added; a slight excess of CrO_3 should be left after long boiling. The liquid is diluted with water (150 c.c.) and the ppd. anthraquinone washed, dried at 100°, and weighed (Luck, *B.* 6, 1347; *v.* also Meister, Lucius, a. Brüning, *Fr.* 16, 61; Paul a. Cownley, *C. N.* 28, 175; Lucas, *C. N.* 30, 190; Nicol, *C. J.* 30, 553; J. T. Brown, *C. J.* 31, 232; Versmann, *C. J.* 30, 347).

Reactions.—1. Conc. HI at 280° forms anthracene hydrides, toluene, and various paraffins. 2. *Chromic acid* produces anthraquinone.—3. *Nitric acid* also produces anthraquinone, and not nitro-anthracene.—4. *Sulphuric acid* forms sulphonates.—5. $COCl_2$ forms the chloride of anthracene (*A*)-carboxylic acid.—6. H_2O_2 produces anthraquinone (Leeds, *B.* 14, 1382).

Combinations.—With picric acid it forms

$C_{14}H_{10}C_6H_2(NO_2)_3OH$ [188°]; red needles.—With dinitrothiophene: $C_{14}H_{10}C_4H_2(NO_2)_2S$ [162°] (Rosenberg, *B.* 18, 1778).—With nitric acid: $C_{14}H_{10}NO_3H$ [125°]. Formed by passing nitrous fumes into anthracene suspended in glacial HOAc at 20°. White needles or prisms, sol. alcohol or benzene, unstable when damp; converted by alkalis into nitroso-anthrone $C_{14}H_9NO_2$, [146°] and nitroso-hydroanthrone $C_{14}H_{11}NO_2$ (Liebermann a. Lindermann, *B.* 13, 1535).—With nitric peroxide: $C_{14}H_{10}N_2O_4$ [194°]. Formed by passing nitrous fumes into anthracene dissolved in glacial acetic acid cooled below 15°. Needles or plates, sl. sol. alcohol and benzene; unstable when damp; converted by alkalis into nitroso-anthrone.—Hydro-anthracene-nitrite, $C_6H_4{:}C_2H_2(ONO)_2{:}C_6H_4$ (?) [125°] is isomeric with the last body. It is formed by the action of HNO_3 on an acetic acid solution of anthracene-di-hydride. Small crystals. Easily soluble in benzene. On boiling with alkalis nitroso-oxanthranol dissolves whilst nitronitrosoanthrone remains insoluble. Oxidation with CrO_3 converts it into anthraquinone (Liebermann a. Landshoff, *B.* 14, 467).

Constitution.—The constitutional formula given above is founded chiefly upon *Formation* 3, 4, and 2, and upon the formula assigned to anthraquinone (*q. v.*). Substitution in one of the benzene nuclei may be indicated by *B* prefixed to a number exactly as in the naphthalene-derivatives; substitution in the C_2H_2 group is indicated by the prefix *A*. But in this dictionary the notation employed for anthracene derivatives is usually exactly the same as that used for other benzene compounds (*v.* BENZENE).

Additional References.—Graebe a. Liebermann, *Z.* [2] 4, 279, 503, 724; 5, 602; 6, 257; Fritzsche, *N. Petersb. Acad. Bull.* 9, 385; 13, 531. *V.* also METHYL-ANTHRACENE, ETHYL-ANTHRACENE, BUTYL-ANTHRACENE, AMYL-ANTHRACENE, and their hydrides; also CHLORO-, BROMO-, NITRO-, ANTHRACENE, ANTHRAMINE, ANTHROL, ANTHRANOL and SULPHO-ANTHRACENE CARBOXYLIC ACID.

Isoanthracene $C_{14}H_{10}$. [134°]. Obtained by passing di-benzyl-toluene, $C_{21}H_{20}$ (from toluene, benzyl chloride, and zinc dust) through a red-hot tube (Weber a. Zincke, *B.* 7, 1156). Laminæ; more soluble than anthracene. Converted by CrO_3 into a quinone $C_{14}H_8O_2$.

Para-anthracene $C_{14}H_{10}$. [244°]. Deposited when solutions of anthracene are exposed to sunlight. V. sl. sol. alcohol, ether, and benzene. Changed into anthracene by fusion. Does not combine with picric acid (Schmidt, *J. pr.* [2] 9, 248).

ANTHRACENE BROMIDE $C_{14}H_{10}Br_2$. Crystals formed by adding bromine to a solution of anthracene in CS_2 at 0° (Perkin, *C. N.* 39, 145). Split up by heat into HBr and bromo-anthracene.

ANTHRACENE CARBOXYLIC ACID $C_{15}H_{10}O_2$ *i.e.* $C_{14}H_9.CO_2H$. [280° corr.]. Two anthracene carboxylic acids can be obtained by distilling dry crude potassium anthracene sulphonate with K_4FeCy_6, and saponifying the mixture of nitriles that results (Liebermann, *B.* 8, 246; 13, 48). They may be separated by baryta-water which forms a soluble salt with the (β)-acid, and an insoluble one with the (γ)-acid. Nevertheless the two acids may be identical.

(β)-Anthracene carboxylic acid. [c. 260°]. Yellow needles (from alcohol). Insol. water, sl. sol. benzene and ether. Gives anthracene when heated with soda-lime, and anthraquinone carboxylic acid when oxidised by CrO_3. Salts with heavy metals are v. sol. water. The acid and its salts show blue fluorescence.

(γ)-Anthracene carboxylic acid. [c. 280°]. Formed also by reducing anthraquinone carboxylic acid with zinc dust and ammonia (Börnstein, *B.* 16, 2609). Small plates or needles. May be sublimed. Sol. acetic acid and hot alcohol, sl. sol. cold alcohol and chloroform. Its solutions have a blue fluorescence. CrO_3 gives anthraquinone carboxylic acid [285°].

Salts.—NaA′: small spangles, sl. sol. water; fluorescent. All the salts of the heavy metals are tolerably insoluble.

Ethyl ether A′Et: [135°], white plates, with blue fluorescence.

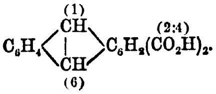
Chloride $C_{14}H_9.COCl$: yellow crystals, soluble in alcohol, ether, benzene, and CS_2 with an intense green fluorescence.

Amide $C_{14}H_9.CONH_2$: [295°], slender yellow needles or plates, sl. sol. alcohol with a blue fluorescence, insol. water, benzene, CS_2 and chloroform.

Anthracene (*A.*)-carboxylic acid $C_6H_4{:}C_2H(CO_2H){:}C_6H_4$. [206°]. From anthracene and $COCl_2$ at 200°, and saponifying the chloride by Na_2CO_3Aq (Graebe a. Liebermann, *B.* 2, 678). Formed also by heating (*A.* 1)-chloro-anthracene (*A.* 2)-carboxylic acid with alcoholic potash (Behla, *B.* 20, 701). Silky needles (from alcohol); decomposed by heat into CO_2 and anthracene. V. sl. sol. water. CrO_3 gives anthraquinone. Cl or Br (1 mol.) gives (*A.* 1)-chloro- (or bromo-) anthracene (*A.* 2)- carboxylic acid. A larger quantity (2 mols.) of Cl or Br give (*A.*)- di-chloro- (or bromo-) anthracene. Conc. H_2SO_4 gives (*B.*)-sulpho-anthracene (*A.*)-carboxylic acid. Salt.—AgA′.

Methyl ether MeA′. [111°]. Yellowish prisms or tables.

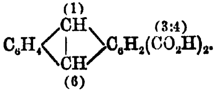
Anthracene-di-*m*-carboxylic acid



$$C_6H_4\left\langle\begin{matrix}\overset{(1)}{CH}\\ |\\ \underset{(6)}{CH}\end{matrix}\right\rangle C_6H_2\overset{(2:4)}{(CO_2H)_2}$$

[above 330°]. Formed by reduction of an ammoniacal solution of the corresponding anthraquinone-*m*-di carboxylic acid with zinc-dust. Crystalline powder. Scarcely sol. water, m. sol. other solvents (Elbs a. Günther, *B.* 20, 1365).

Anthracene-di-carboxylic acid



$$C_6H_4\left\langle\begin{matrix}\overset{(1)}{CH}\\ |\\ \underset{(6)}{CH}\end{matrix}\right\rangle C_6H_2\overset{(3:4)}{(CO_2H)_2}$$

[345°]. Formed by reduction of an ammoniacal solution of anthraquinone-di-carboxylic acid [340°] with zinc-dust. Yellow crystalline powder. Scarcely sol. water, sl. sol. other solvents (Elbs a. Eurich, *B.* 20, 1363).

ANTHRACENE CHLORIDE $C_{14}H_{10}Cl_2$. From anthracene dissolved in CS_2 at 0° by passing in Cl (Perkin, *C. J.* 31, 209). Needles (from benzene). Splits up into HCl and chloranthracene even in the cold.

ANTHRACENE HYDRIDES.

Anthracene di-hydride $C_{14}H_{12}$. [108°]. (313°). Formed by heating anthracene at 160° with HI and red P, or by treating a solution in alcohol (95 p.c.) with sodium-amalgam. Prepared by heating anthraquinone (30 pts.), HI (140 pts. of S.G. 1·8), and red P (10 pts.) with inverted condenser for one hour on a sand bath (Liebermann, *A. Suppl.* 7, 265; 212, 5). Large monoclinic plates (from alcohol) or needles (by sublimation). Insol. water, v. sol. alcohol, ether, and benzene. Volatile with steam. Its solutions fluoresce blue.

Reactions.—1. Warm conc. H_2SO_4 forms anthracene and SO_2.—2. Br added to its solution in CS_2 forms di-bromo-anthracene.—3. Conc. *nitric acid* forms hydro-anthracene-nitrite (*v. sup.*) and dinitroanthrone.—4. CrO_3 gives anthraquinone.

Anthracene hexa-hydride $C_{14}H_{18}$. [63°]. (290°). From oxy-anthraquinone (or anthracene dihydride), fuming HI and red P by boiling for 20 hours (Liebermann, *A.* 212, 25; *Suppl.* 7, 273). Plates (from alcohol). Volatile with steam; v. sol. alcohol, ether, and benzene. At a red heat it is split up into hydrogen and anthracene.

ANTHRACENE - HYDRIDE CARBOXYLIC ACIDS.

Anthracene-di-hydride carboxylic acid $C_{15}H_{12}O_2$ *i.e.* $C_{14}H_{11}(CO_2H)$. [203°]. Formed, together with the following acid, by reduction of anthracene-carboxylic acid, [280° cor.], with sodium-amalgam (Börnstein, *B.* 16, 2612). Colourless plates. V. sol. ordinary solvents.

Anthracene-tetra-hydride carboxylic acid $C_{14}H_{13}(CO_2H)$. [165°]. Colourless trimetric tables.

Anthracene-hexa-hydride carboxylic acid $C_{14}H_{15}(CO_2H)$. [232°]. Formed by reduction of anthracene-carboxylic acid by heating it with HI (1·7) and P at 220° (B.). Slender needles.

ANTHRACENE-DI-HYDRIDE SULPHONIC ACID $C_{14}H_{11}.HSO_3$. Prepared by reduction of sodium anthraquinone sulphonate with HI (S.G. 1·8) and red P (Liebermann, *B.* 12, 189, *A.* 212, 44). Decomposed by fusion with KOH with formation of anthracene and anthracene hydride. NaA′aq: long soluble needles.—BaA′$_2$.—CaA′$_2$.

ANTHRACENE SULPHONIC ACID $C_{14}H_9SO_3H$.

Formation.—From anthraquinone sulphonic acid, HI (S.G. 1·7), and red P, by boiling for half an hour (Liebermann, *A.* 212, 48).

Preparation.—From sodium anthraquinone sulphonate (500 g.), zinc dust (750 g.) and ammonia (3 litres of S.G. ·88), at 100° (*A.* 212, 57; *B.* 15, 852). On oxidation by HNO_3 it gives anthraquinone sulphonic acid.

Salts.—NaA′4aq, v. sl. sol. water.—BaA′$_2$.—PbA′$_2$ 2aq.

The existence of (α)- and (β)-anthracene sulphonic acids amongst the disulphonic acids obtained by sulphonation of anthracene (Linke, *J. pr.* [2] 11, 222) has been denied by Liebermann (*B.* 12, 592).

(α)-Anthracene-disulphonic acid $\left[1\,\substack{2\\3}\right]$ $C_6H_3(SO_3H):C_2H_2:C_6H_3SO_3H$ $\left[\substack{2\\3}\,4\right]$.

Preparation.—1 pt. of anthracene is gently heated on a water bath with 3 pts. of H_2SO_4 for an hour. After dilution with water, the filtered solution is neutralised with $PbCO_3$, and the lead salts converted into the sodium salts.

Since the sodium salt of the (α)-acid is much less soluble in water containing Na_2CO_3 than the sodium salt of the (β)-acid it can be readily separated from the latter (which is formed simultaneously) (Liebermann a. Boeck, *B.* 11, 1613; 12, 182, 1287).

Properties.—Minute needles. By fusion with KOH it gives (α)-dioxyanthracene (chrysazol), which is converted on oxidation into chrysazin *v.* DI-OXY-ANTHRAQUINONE.

Salts.—Na$_2$A″ 4aq.—K$_2$A″ aq.—CaA″ 5aq.—BaA″ 4aq.

(β)-Anthracene-disulphonic acid $\left[1\,\substack{2\\3}\right]$ $C_6H_3(SO_3H):C_2H_2:C_6H_3.SO_3H$ $\left[\substack{2\\3}\,1\right]$.

Preparation.—1 pt. of anthracene is heated to 100°C. with 3 pts. of H_2SO_4 till half has dissolved. It is separated from the (α)-acid, simultaneously formed, by conversion into the sodium salt. By fusion with KOH it gives a dioxyanthracene, which on oxidation is converted into anthrarufin *v.* DI-OXY-ANTHRAQUINONE.

Salts.—Na$_2$A″ 3aq; white leaflets, easily soluble with a blue fluorescence.—BaA″ 4aq; white leaflets.—A″Pb: crystalline pp.—CaA″ 3aq (Liebermann a. Boeck, *B.* 11, 1613; 12, 182, 1287).

Anthracene - di - sulphonic acid (*Flav-*). $C_{14}H_8(SO_3H)_2$. Prepared by reduction of sodium (α)-anthraquinone di-sulphonate with zinc-dust and NH_3 (Schüler, *B.* 15, 1807).

Salts.—A″Na$_2$: soluble crystals, its solutions have a blue-violet fluorescence.—A″Ba: white crystalline powder.

ANTHRACHRYSONE *v. tetra*-OXY-ANTHRAQUINONE.

ANTHRACYL-AMINE *v.* ANTHRAMINE.

ANTHRAFLAVIC ACID *v.* DI-OXY-ANTHRAQUINONE.

ANTHRAGALLOL *v.* (1, 2, 3)-*tri*-OXY-ANTHRAQUINONE.

ANTHRAHYDROQUINONE *v.* OXANTHRANOL.

ANTHRAMINE $C_{14}H_{11}N$ *i.e.* $C_6H_4:(C_2H_2):C_6H_3NH_2$. *Anthracylamine. Amido-anthracene. Anthrylamine.* [237°].

Formation. — 1. By heating amido-anthraquinone with HI and P.—2. By heating anthrol with acetamide at 280° and saponifying the acetyl derivative so produced.—3. By heating anthrol with 10 p.c. aqueous NH_3 at 250°; the yield is nearly theoretical.—4. By heating anthrol with alcohol and ammonia at 170°.

Properties.—Yellow plates (from alcohol). May be sublimed; sl. sol. alcohol, the solution having a splendid green fluorescence. Is a weak base, dissolving with difficulty in boiling HCl. Forms a blue mass when fused with arsenic acid. Is readily methylated.

Reactions.—1. Does not give the carbamine or mustard oil tests.—2. Boiling HOAc gives di-anthramine.—3. Chloroform and alcoholic potash give rise to di-anthryl-formamidine $C_{14}H_9.NH.CH:N.C_{14}H_9$.—4. *Nitrous acid* gives $C_{28}H_{21}N_3O$, [250°], a body which forms a red solution in CS_2, and a blue solution in H_2SO_4.

Salts.—B′HCl: white iridescent plates, sl. sol. water; formed by adding HCl to an alcoholic

solution of the base. Its solution does not fluoresce.—$B'_2H_2SO_4$: v. sl. sol. water.

Acetyl derivative $C_{14}H_9NHAc$. [240°]. Plates. Its alcoholic solution fluoresces blue. CrO_3 gives acetyl-amido-anthraquinone.

Formyl derivative $C_{14}H_9NH.CHO$. [242°]. Small yellowish-green crystals, sl. sol. alcohol, with green fluorescence.

References.—Roemer, *B.* 15, 223; Liebermann a. Bollert, *B.* 15, 226, 852; 16, 1635; *A.* 212, 57.

Di-anthramine $C_{28}H_{19}N$ *i.e.* $(C_{14}H_9)_2NH$. *Di-anthracylamine.* Prepared by boiling anthramine with acetic acid (Bollert, *B.* 16, 1636). Does not melt at 320°. Small glistening plates. Very sparingly soluble in all solvents.

ANTHRAMINE-DI-HYDRIDE $C_{14}H_{11}.NH_2$. Slender colourless needles. Very soluble in alcohol. Formed by reduction of anthramine with sodium-amalgam.—B'HCl: sparingly soluble white needles (Liebermann a. Bollert, *B.* 15, 853).

ANTHRANIL C_7H_5NO *i.e.* $C_6H_4<\begin{smallmatrix}CO\\NH\end{smallmatrix}>$ (?).

o-Amido-benzoic lactam. (c. 213°). V.D. 4·14 (obs.). Formed by reduction of *o*-nitrobenzaldehyde with tin and acetic acid (Friedlander a. Henriques, *B.* 15, 2105). Colourless oil; volatile with steam. Soluble in ordinary solvents, but sparingly in water. Very weak basic properties. Reduces salts of gold and silver to the metal. By alkalis it is converted into anthranilic acid of which it is the anhydride. *Double compound* $C_7H_5NOHgCl_2$: [174°]; slender needles, sol. alcohol and hot water, sl. sol. cold water.

Benzoyl derivative $C_6H_4<\begin{smallmatrix}CO\\|\\NBz\end{smallmatrix}$. [123°]. (above 360° with decomposition). Formed by heating isatoïc acid with BzCl (E. v. Meyer, *J. pr.* [2] 33, 19). Long white needles; readily takes up H_2O forming benzoyl-anthranilic acid (Friedlander a. Wleugel, *B.* 16, 2229).

ANTHRANIL *v*-**CARBOXYLIC ACID** *v.* Isatoic acid.

ANTHRANILIC ACID *v.* *o*-Amido-benzoic acid.

ANTHRANOL $C_{14}H_{10}O$ *i.e.*

(163°-170°). From anthraquinone (30 g.), HI (140 g. of S.G. 1·75), and red P (8 g.), by 15 minutes' digestion (Liebermann, *A.* 212, 6). Needles (from benzene). Its alcoholic solution shows blue fluorescence. Decomposed by heat, becoming greenish. Dissolves in aqueous KOH, forming a yellow liquid, whence CO_2 pps. the anthranol. The alkaline solution is oxidised by air, some anthraquinone being formed. CrO_3 in glacial HOAc completely oxidises anthranol to anthraquinone.

Acetyl derivative. [126°-131°]. White needles (from dilute alcohol).

ANTHRANOL DIHYDRIDE

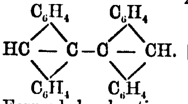
$$C_6H_4<\begin{smallmatrix}CH_2\\CH(OH)\end{smallmatrix}>C_6H_4.\quad [76°].$$

Preparation.—**50 grms. of anthraquinone are mixed with 100 grms. of zinc dust and heated over a water-bath with 300 c.c. ammonia and 200 c.c. of water. The liquid turns at first blood-red from oxanthranol, but after three hours this is reduced, the liquid becoming yellow. The liquid is filtered, the pp. dried at 15°, and extracted with boiling benzoline (40°-60°), from which the anthranol dihydride crystallises on cooling (H. R. v. Perger, *J. pr.* [2] 23, 139).**

Properties.—Slender satiny needles, which dissolve in benzoline, forming a solution with bluish fluorescence. May be crystallised from boiling water, but by long-continued boiling with water or with alcohol it is converted into anthracene:

$$C_6H_4<\begin{smallmatrix}CH_2\\CH(OH)\end{smallmatrix}>C_6H_4 = C_6H_4<\begin{smallmatrix}CH\\|\\CH\end{smallmatrix}>C_6H_4+H_2O.$$

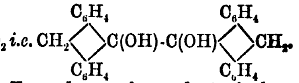
DIANTHRANYL $C_{28}H_{18}$ *i.e.*



[300°]. Yellowish plates. Formed by heating anthrapinacone $C_{28}H_{22}O_2$ with acetyl chloride (K. Schulze, *B.* 18, 3035).

ANTHRAPINACONE

$C_{28}H_{22}O_2$ *i.e.*

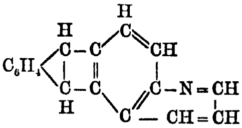


[c. 182°]. Formed as a by-product of the reduction of anthraquinone to dihydroanthranol by means of zinc-dust and NH_3. Long slender white needles. Sol. hot benzene, toluene, or xylene, sl. sol. alcohol, insol. petroleum-ether. On heating with acetyl chloride, $2H_2O$ is removed giving dianthranyl $C_{28}H_{18}$ (Schulze, *B.* 18, 3034).

ANTHRAPURPURIN *v.* *Tri*-Oxy-anthraquinone.

ANTHRAQUINOL *v.* Oxanthranol.

ANTHRAQUINOLINE $C_{17}H_{11}N$ *i.e.*



[170°]. (446°).

Formation.—1. By heating alizarin-blue with zinc-dust.—2. By heating a mixture of anthramine, nitrobenzene, glycerin, and H_2SO_4 (Graebe, *B.* 17, 170; *A.* 201, 344).

Properties.—Tables, insol. water, sol. alcohol and ether; its solutions show intense blue fluorescence. Its salts are yellow and possess in solution an intense green fluorescence. B'HCl.—$B'_2H_2PtCl_6$.—B'HI.—$B'H_2SO_4$.

Combinations.—With picric acid it forms $C_{17}H_{11}N\ C_6H_2(NO_2)_3OH$: slender yellow needles. With ethyl iodide: B'EtI; golden needles, v. sol. hot, sl. sol. cold, water.

Quinone $C_{17}H_9NO_2$. [185°]. Formed from the preceding by CrO_3. Yellow prisms or needles, insol. water, sol. in alcohol and ether. Salts.—B'HCl: sulphur-yellow needles, sl. sol. water, but slowly decomposed by it.—$B'_2H_2PtCl_6$. Picric acid compound $B'C_6H_3N_3O_7$: golden needles.

ANTHRAQUINONE

$C_{14}H_8O_2$ *i.e.* $C_6H_4<\begin{smallmatrix}CO\\CO\end{smallmatrix}>C_6H_4$. Mol. w. 208. [273°]. S. (alcohol) ·05 at 18°; 2·25 at 78°. V.D. 7·33 (calc. 7·20) (Graebe, *B.* 5, 15).

Formation.—1. By oxidation of anthracene (Laurent, *A. Ch.* [2] 60, 220; 72, 415; *A.* 34, 287; Anderson, *C. J.* 15, 44).—2. From phthalyl chloride by heating with benzene and zinc-dust in sealed tubes at 220° (Piccard, *B.* 7, 1785) or by treatment with $AlCl_3$ (Friedel a. Crafts, *Bl.* [2] 29, 49).—3. *By dry distillation of calcium* phthalate (Panaotovits, *B.* 17, 312).—4. Together with benzophenone by distillation of calcium benzoate (Kekulé a. Franchimont, *B.* 5, 908).—5. By heating *o*-(but not *p*-) benzoyl-benzoic acid with P_2O_5 at 200° and extracting with benzene (yield 20 p.c.; Behr a. Van Dorp, *B.* 7, 578).—6. In small quantity, by distilling benzoic acid with P_2O_5 (K. a. F.).—7. From phenyl *o*-tolyl ketone, MnO_2, and H_2SO_4Aq (Behr a. Dorp, *B.* 6, 753; 7, 16).—8. By acting on *o*-bromo-benzyl bromide dissolved in ether with Na and oxidising the product (anthracene) with CrO_3 (Jackson a. White, *Am.* 2, 390).—9. By action of water on 'anthraquinone chloride' $C_{14}H_8Cl_2O$, obtained by passing chlorine into phenyl *o*-tolyl ketone at 110° (Thörner a. Zincke, *B.* 10, 1479).

Preparation.—Anthracene is dissolved in glacial acetic acid; $K_2Cr_2O_7$ or CrO_3 is added; the liquid is then heated to 100°, the acetic acid is distilled off and the anthraquinone ppd. by water. Large quantities are prepared by oxidising anthracene (100 kilos.) with $K_2Cr_2O_7$ (150 kilos.) sulphuric acid (200 kilos.) and water (2,000 kilos.).

Properties.—Yellow needles (by sublimation). Insol. water, v. sl. sol. alcohol, sl. sol. benzene. Not attacked by alcoholic KOH at 200°; or by cold Br.

Reactions.—1. *Bromine* at 100° forms di-bromo-anthraquinone (*q.v.*).—2. HI and P form anthranol and anthracene dihydride.—3. Heated with *zinc dust* to dull redness it is reduced to anthracene.—4. *Zinc dust* and aqueous NaOH give oxanthranol, $C_6H_4{:}(C_2H_2O_2){:}C_6H_4$ (*q.v.*): when alkyl iodides are added alkyl oxanthranols are got. When stronger soda is used and the alkyl iodide is not added until the reduction is complete, alkyl-hydro-anthranols (*v.* HYDRO-ANTHRANOL) are got (Liebermann, *A.* 212, 100).—5. *Zinc dust* and aqueous NH_3 give dihydro-oxanthranol, $C_6H_4{:}(C_2H_4O_2){:}C_6H_4$.—6. PCl_5 diluted with PCl_3 at 200° forms chlorinated anthraquinones (Graebe a. Liebermann, *A.* 160, 121).—7. *Potash-fusion* at 250° forms potassium benzoate.

Constitution.—The formation of anthraquinone from phthalyl chloride (*q. v.*) and benzene might be thought to indicate the formula  This formula is open to several objections:—(*a*) the group $C_6H_4{:}C$ is unknown; (*b*) it represents a lactone which should be converted by KOH into an oxy acid: (*c*) anthraquinone reacts with hydroxylamine while phthalide and its derivatives do not (E. v. Meyer, *J. pr.* [2] 29, 139, 496; V. Meyer, *B.* 17, 818). There remains the formula  $C_6H_4{<}\begin{smallmatrix}CO\\CO\end{smallmatrix}{>}C_6H_4$, which agrees with that of anthracene  and must therefore be adopted. Bromo-phthalic acid, benzene, and $AlCl_3$ give bromo-benzoyl-benzoic acid, $CO_2H.C_6H_3Br.CO.C_6H_5$, in which it is evident that the carbonyls are *o* to one another. Conc. H_2SO_4 condenses this acid to bromo-anthraquinone, whence potash-fusion forms an *oxy-anthraquinone from which phthalic (not oxy-phthalic) acid* can be obtained by nitric acid. Hence the two carbonyls are *o* to one another in both benzene nuclei (Pechmann, *B.* 12, 2125).

Derivatives of anthraquinone are described as CHLORO-ANTHRAQUINONE, BROMO-ANTHRAQUINONE, OXY-ANTHRAQUINONE, OXY-METHYL-ANTHRAQUINONE, METHYL-ANTHRAQUINONE.

ANTHRAQUINONE CARBOXYLIC ACID $C_{15}H_8O_4$ *i.e.* $C_6H_4{:}(C_2O_2){:}C_6H_3CO_2H$. [282°–284°]. Obtained by boiling methyl-anthracene (Weiler, *B.* 7, 1186; O. Fischer, *B.* 7, 1196; Liebermann, *A.* 183, 166; Japp a. Schultz, *B.* 10, 1051), methyl-anthraquinone (Hammerschlag, *B.* 11, 82), or anthracene carboxylic acid [280°] (Liebermann a. v. Rath, *B.* 8, 248), with CrO_3 and HOAc, or the compound $C_{19}H_{14}O$ (obtained by action of conc. H_2SO_4 on amyl-oxanthranol) with CrO_3 and H_2SO_4 (Liebermann, *A.* 212, 97).

Properties.—Compact yellow prisms (from alcohol); yellow needles (by sublimation); v. sl. sol. HOAc, benzene, and alcohol, v. sol. acetone. Decomposed by heat into CO_2 and anthraquinone. The sodium salt is insol. NaOHAq.

Salts.—BaA'_2(?Aq) needles, v. sol. hot water.—CaA'_2(?Aq).

The following derivatives are got from the acid obtained by oxidising methyl-anthraquinone (Liebermann a. Glock, *B.* 17, 888).

Ethyl ether A'Et: [147°], needles, easily soluble in alcohol.

Chloride $C_{14}H_7O_2.COCl$: [147°], needles, very stable towards water.

Amide $C_{14}H_7O_2.CO.NH_2$: [above 280°], needles, very stable compound.

Anilide $C_{14}H_7O_2.CO.NHPh$: [260°], needles, very sparingly soluble in most solvents.

(γ)-Anthraquinone carboxylic acid. [285°]. From the corresponding anthracene carboxylic acid (Liebermann a. Bischof, *B.* 13, 49). Yellow needles (from glacial HOAc). Its alkaline solutions do not fluoresce. Its barium salt is v. sl. sol. water. This acid may be identical with the preceding.

Anthraquinone-di-*m*-carboxylic acid  $C_6H_4{<}\begin{smallmatrix}\overset{(1)}{CO}\\ \underset{(6)}{CO}\end{smallmatrix}{>}C_6H_2\overset{(2:4)}{(CO_2H)_2}$. [above 330°]. Formed by oxidation of the corresponding *m*-di-methyl-anthracene. Yellow needles. Nearly insol. water, sl. sol. other solvents. Dissolves in aqueous NH_3 with a red colour; the NH_4 salt crystallises in easily soluble small red warts; its solution gives with $AgNO_3$ a reddish pp. of $A''Ag_2$. By zinc-dust and aqueous NH_3 the acid is reduced to anthracene-*m*-di-carboxylic acid (Elbs a. Günther, *B.* 20, 1364).

Anthraquinone-di-carboxylic acid  $C_6H_4{<}\begin{smallmatrix}\overset{(1)}{CO}\\ \underset{(6)}{CO}\end{smallmatrix}{>}C_6H_2\overset{(3:4)}{(CO_2H)_2}$. [340°]. Formed by oxidation of di-methyl-anthraquinone [183°] by HNO_3 (1·2) at 220°. Yellow needles. Scarcely sol. water, sl. sol. most other solvents. Dissolves in aqueous NH_3 with a red colour. On heating it loses H_2O, giving the anhydride. By zinc-dust and aqueous NH_3 it is reduced to anthracene-di-carboxylic acid [345°]. The solution of the NH_4 salt gives pps. with $CaCl_2$, $Pb(OAc)_2$, and $AgNO_3$.

Anhydride $C_6H_4.C_2O_2.C_6H_2\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle O$: [290°]; sublimes in small yellow needles (Elbs a. Eurich, *B.* 20, 1362).

ANTHRAQUINONE-OXIM

$C_6H_4\left\langle\begin{matrix}C(NOH)\\CO\end{matrix}\right\rangle C_6H_4$.

Formed by heating anthraquinone with hydroxylamine hydrochloride and alcohol at 180° (Goldschmidt, *B.* 16, 2179). Red crystalline powder. Sublimes without melting above 200°. Dissolves in H_2SO_4 with an intense yellow colour.

ANTHRAQUINONE SULPHONIC ACID $C_{14}H_8SO_5$ *i.e.* $C_6H_4:(CO)_2:C_6H_3.SO_3H$. Formed together with the disulphonic acid by heating anthraquinone (1 pt.) with H_2SO_4 ($2\frac{1}{2}$ pts.) at 260°. Also from diamido-anthraquinone sulphonic acid by diazo reaction; and from *o*-benzoyl-benzoic acid and fuming H_2SO_4 (Liebermann, *A.* 160, 131; *Suppl.* 7, 805; v. Perger, *J. pr.* [2] 19, 218).

Properties.—Yellow scales, v. sol. water and alcohol, v. sl. sol. H_2SO_4 and ether.

Reactions.—1. Fused with *potash* it forms alizarin, oxy-anthraquinone, and benzoic, *p*-oxy-benzoic and protocatechuic acids.—2. HI and P form anthracene sulphonic acid and its dihydride.—3. Anthracene sulphonic acid is also produced by *sodium-amalgam*, and by *zinc-dust* and *ammonia.*—4. *Ammonia* at 190° forms amido-anthraquinone.—5. *Distillation of the sodium salt* produces, besides small quantities of anthraquinone and oxyanthraquinone, chiefly a compound $C_{28}H_{14}O_6$ which melts far above 300°. This compound forms minute reddish-yellow needles (from glacial HOAc), sl. sol. HOAc, toluene, phenol, and aniline, v. sl. sol. alcohol. At a high temperature it may be sublimed. It is insol. alkalis, but forms a crimson solution in conc. H_2SO_4. Distilled with zinc dust it yields anthracene. Fused with potash it gives alizarin. Its constitution is perhaps $C_6H_4:(CO)_2:C_6H_3O.C_6H_3O:(CO)_2:C_6H_4$. Chromic acid oxidises it to colourless $C_{14}H_6O_4$, [296°], possibly $C_6H_4:(CO)_2:C_6H_2O_2$. This forms transparent plates, insol. aqueous alkalis, v. sl. sol. boiling benzene, sl. sol. acetic acid, m. sol. aniline. It may be sublimed. Alcoholic KOH forms a violet solution decolorised by shaking with air. Distillation with zinc dust produces anthracene (A. G. Perkin a. W. H. Perkin, jun., *B.* 18, 1723; *C. J.* 47, 682).

Salts.—BaA'_2aq; small leaflets, sl. sol. water.—CaA'_2 2aq: sl. sol. water.—NaA'aq: white leaflets, sl. sol. water.

Chloride $C_{14}H_7O_2.SO_2Cl$. [193°]. Light yellow plates; sol. benzene and acetic acid, v. sl. sol. alcohol and ether. Converted by dimethyl-aniline into the sulphone $C_{14}H_7O_2.SO_2.C_6H_4NMe_2$. [171°].

Amide $C_{14}H_7O_2.SO_2NH_2$. [261°]. Long yellow needles; almost insoluble in alcohol, chloroform and CS_2.

Anilide $C_{14}H_7O_2.SO_2NHPh$. [198°]. Long prisms; sol. alcohol and acetic acid.

Additional References.—Liebermann, *A.* 212, 42; *B.* 12, 189, 1293, 1597; McHoul, *B.* 13, 692.

(α)-Anthraquinone disulphonic acid $C_{14}H_6O_2(SO_3H)_2$. When anthraquinone (1 pt.) is heated with fuming H_2SO_4 ($2\frac{1}{2}$ pts.) at 170°, or when dichloro-anthracene or di-bromo-anthracene is similarly treated, a mixture of (α) and (β) disulphonic acids is got. The salts of the (α) acid are less soluble and less crystalline than those of the (β) acid. The (α) acid is converted by potash-fusion into anthraflavin (di-oxy-anthraquinone), oxy-anthraquinone sulphonic acid, and flavopurpurin (tri-oxy-anthraquinone).

Salts.—Na_2A'' 7aq.—BaA''aq.—PbA''aq.

(β)-Anthraquinone di-sulphonic acid. Prepared as above. Potash-fusion produces iso-anthraflavin (di-oxy-anthraquinone) and iso-purpurin (tri-oxy-anthraquinone). The sodium salt heated with NH_3Aq at 180° produces $C_{14}H_5(OH)(NH_2)(SO_3H)$ (Bourcart, *Bl.* [2] 33, 264).

Salts.—Na_2A'' 4aq.—BaA'' 2aq.—PbA''aq.

χ-Anthraquinone-disulphonic acid $C_{14}H_8O_8S_2$ *i.e.* $C_6H_3(SO_3H):(CO)_2:C_6H_3.SO_3H$. Prepared by oxidation of (β)-anthracene-di-sulphonic acid. On fusion with KOH it first gives chrysazin (di-oxy-anthraquinone) and then oxychrysazin (tri-oxy-anthraquinone).

Salts.—Na_2A'' 4aq: yellow prisms.

(ρ)-Anthraquinone-disulphonic acid $C_{14}H_8O_8S_2$ *i.e.* $\left[3\,\begin{smallmatrix}1\\2\end{smallmatrix}\right]$ $C_6H_3(SO_3H)(CO)_2C_6H_3SO_3H$ $\left[\begin{smallmatrix}1\\2\end{smallmatrix}\,6\right]$. Prepared by oxidation of (α)-anthracene-disulphonic acid. On fusion with KOH it first gives anthrarufin (di-oxy-anthraquinone) and then oxy-chrysazin. Salts.—Na_2A'' 5aq: yellow leaflets, sol. water.

References.—Graebe a. Liebermann, *A.* 160, 134; *B.* 3, 636; 7, 805; Liebermann a. Dehnst, *B.* 12, 1288; Perkin, *C. N.* 22, 37; *A.* 158, 323; Schunck a. Roemer, *B.* 9, 379; 10, 1821.

ANTHRAQUINONE CHLORIDE *v.* ANTHRAQUINONE, *Formation* 9.

ANTHRARUFIN *v. Di*-OXY-ANTHRAQUINONE.

ANTHROL $C_{14}H_{10}O$ *i.e.* $C_6H_4(C_2H_2)C_6H_3OH$.

Formation.—1. From oxy-anthraquinone and HI.—2. By fusing anthracene sulphonic acid with potash.

Preparation.—Crude sodium anthraquinone sulphonate (1 pt.) is heated on a water bath for a few hours with $1\frac{1}{2}$ pts. of zinc-dust and 7 pts. of conc. ammonia; the anthracene sulphonate thus obtained is fused with NaOH. Leaflets or needles (from dilute alcohol). Insol. water, v. sol. alcohol, acetone, or ether. Decomposes at 200°. Insol. in NH_3Aq, soluble in KOHAq or baryta-water, forming a yellow solution with green fluorescence. Its alcoholic solution shows a violet fluorescence. Conc. H_2SO_4 gives a yellow solution, turned blue by heat. A drop of fuming HNO_3 added to its solution in glacial acetic acid gives a transient green colour. Its alcoholic solution reduces warm $AgNO_3$.

Acetyl derivative [198°]. Microscopic leaflets. Difficultly soluble in cold acetic acid, easily in C_6H_6. CrO_3 in HOAc converts it into the acetyl derivative of oxy-anthraquinone.

Ethyl derivative [146°]. Needles.

Methyl derivative [c. 178°].

References.—Liebermann a. Hörmann, *B.* 12, 589; L. a. Hagen, *B.* 15, 1427; L. a. Bollert, *B.* 15, 226; L., *A.* 212, 26, 49.

Isomerides have been described by Linke, *J. pr.* [2] 11, 227.

ANTHROL-SULPHONIC ACID $C_{14}H_8(OH)(SO_3H)$. Formed by careful fusion of anthracene-di-sulphonic acid with KOH.

Salts.—A′Na: crystals sl. sol. cold water.—A'_2Ba: plates or needles (Schüler, *B.* 15, 1808).

ANTHROPIC ACID. Shown by Heintz (*P.* 84, 238; 87, 233) to be a mixture of palmitic and stearic acids.

ANTHROPOCHOLIC ACID $C_{18}H_{28}O_4 2aq.$ [145°]. $[\alpha]_D$ 50°. The cholic acid of human bile. The bile is extracted with alcohol; evaporated; extracted with dry alcohol, and the pp. (probably a mixture of sodium glyco-, and tauro-, anthropocholates) is decomposed by boiling with baryta-water (Bayer, *H.* 3, 293).

Properties.—Groups of prisms, insol. water, v. e. sol. alcohol, v. sol. ether, m. sol. chloroform. Lævorotatory. Fusion changes it into an amorphous dyslysin $C_{18}H_{26}O_3$.

Salts.—KA′: v. e. sol. water.—BaA'_2 (? Aq): silky plates, sl. sol. water.

ANTHROXANIC ACID

$$C_8H_5NO_3 \text{ i.e. } C_6H_4\left\langle\begin{array}{l} C-CO_2H \\ \,|\;\;>O \\ N \end{array}\right. \quad (?)$$

[191°]. Obtained by oxidation of anthroxanic aldehyde with dilute $KMnO_4$ (Schillinger a. Wleügel, *B.* 16, 2224). White felted needles. Sol. acetone and hot water, v. sl. sol. cold water, sl. sol. alcohol, ether, and benzene. Strong acid. On reduction with $FeSO_4$ and NH_3 it yields isatic acid.

ANTHROXANIC ALDEHYDE

$$C_8H_5NO_2 \text{ i.e. } C_6H_4\left\langle\begin{array}{l} C-CHO \\ \,|\;\;>O \\ N \end{array}\right. \quad (?)$$

[73°]. Obtained by heating a solution of *o*-nitro-(*β*)-oxy-cinnamic acid in an equal weight of acetic acid to 100° for a few hours, diluting the product with water, neutralising with $CaCO_3$, distilling with steam, and extracting the distillate with ether. Long yellowish needles. Sublimable. Volatile with steam. Easily soluble in hot water and in most other solvents except ligroine.

The addition of zinc-dust to the dilute ammoniacal solution produces a reddish-violet colouration. It combines with bisulphites and reddens fuchsin-sulphurous acid. With aniline it yields a crystalline anilide which melts at about 40° (Schillinger a. Wleügel, *B.* 16, 2222).

DI-ANTHRYL-FORMAMIDINE *v.* ANTHRAMINE, *reaction* 3.

ANTIARIN $C_{14}H_{20}O_5 2aq$ (?). [221°]. Poisonous substance in the milky juice of *Antiaris toxicaria* or Upas Antjar, used to poison arrows (Mulder, *A.* 28, 304; Ludwig a. de Vry, *Z.* 1869, 351; Pelletier a. Caventou, *A. Ch.* 26, 57).

ANTIMONIDES. — Binary compounds, or rather alloys, of Sb with more positive metals. Most of these bodies are of somewhat vague compositions; some occur as minerals (*v.* ANTIMONY, *Combinations*, No. 10).

ANTIMONY. Sb. (*Antimonium*, or *Stibium metallicum; Regulus antimonii*). At. w. 120. Mol. w. probably 120, *v.* Biltz a. Meyer, *B.* 22, 725. [about 425°] (between 1090° and 1450°) (Carnelley a. Williams, *C. J.* 35, 566). S.G. 6·71 to 6·86; $\frac{c.\,15^\circ}{4^\circ}$, 6·697 (Schröder, *J.* 1859. 12) S.G. (melted) 6·53 to 6·65 (Playfair a. Joule, *C. S. Mem.* 3, 57). S.H. (0°–100°) ·0495 (Bunsen *P.* 141, 1); ·0523 (Kopp, *A. Suppl.* 3, 66); (0°–33°) ·049; (−21° to 0°) ·048; (−75° to −21°) ·047 (Pebal a. Jahn, *W.* 27, 584). C.E. (cub. 0°–100°) ·003161 (Matthiessen, *P.* 130, 50); (lin. 40°) ·00001152 (Fizeau, *C. R.* 68, 1125). T.C. (Ag = 100) 4·03 (Lorenz, *W.* 13, 422). E.C. (Hg at 0° = 1) 2·05 at 0°, 1·42 at 100° (Lorenz, *l.c.*). Chief lines in spectrum, 6128·5, 6078, 6003·5 (Thalén, *A. Ch.* [4] 18, 243). Crystallises in rhombohedra, approaching cubes (Marx, *S.* 59, 211); isomorphous with As, Bi, and Te.

Occurrence.—Native; but chiefly as sulphide Sb_2S_3 (*Stibnite*), and as double sulphide with PbS, CuS, Ag_2S, NiS, &c.; as oxide in small quantities; in various iron ores; in ferruginous mineral waters; in some gas coals; in certain river sands (Campbell, *P.M.* [4] 20, 304; 21, 318).

Preparation.—The sulphide is fused, to separate gangue, and roasted in air; the oxide thus produced is reduced by heating with charcoal or coal. Or the sulphide is reduced by charcoal or by iron. The crude metal (16 parts) is purified by fusion with dry Na_2CO_3 (2 parts) and Sb_2S_3 (1 part), for an hour in a Hessian crucible; the regulus is separated and again fused for an hour with $1\frac{1}{2}$ parts Na_2CO_3, and this is repeated with 1 part Na_2CO_3 a second time (Bensch, *A.* 5, 20). Or the crude metal is fused with $NaNO_3$ and Na_2CO_3 (details, *v.* Meyer, *A.* 66, 238). Pure Sb is prepared by Dexter (*J. pr.* 18, 449) by fusing dry H_3SbO_4 with lampblack, and then with a little Sb_2O_3. Capitaine (*P.* 100, 563) prepares the pure metal by heating tartar-emetic in a closed crucible. Bongartz (*B.* 16, 1942) digests pure $SbCl_3$ with $(NH_4)_2SAq$ in Pt vessels, electrolyses, fuses with pure Na_2CO_3, treats with dilute HClAq, cleans with sea sand, and dries. Cooke (*P. Am. A.* [2] 5, 1) reduces $NaSbO_3$ by KCN, and fuses the Sb under Sb_2O_3 for several hours. Pure crystalline Sb may be obtained, according to Pfeifer (*A.* 209, 161), by electrolysing a solution of $SbCl_3$ in HClAq containing not more than 7 p.c. $SbCl_3$. Metallic antimony seems to have been known since the end of the 15th century. The sulphide was known to the ancients as *Stibium*.

Properties.—Brittle, hard, silver-white, metal-like; easily crystallised, isomorphous with As and Te, melts easily [425°]; volatilises at bright red heat in open vessel with simultaneous production of Sb_4O_6; scarcely volatilises in absence of air; but slightly volatile *in vacuo* at 292° (Demarçay, *C. R.* 95, 183); may be distilled in H at white heat. Unchanged in air at ordinary temperatures; melted on charcoal before blowpipe and then exposed to stream of air, pure Sb burns easily to Sb_4O_6; if traces of lead or iron are present a yellow or reddish sublimate is produced on burning before blowpipe. By electrolysis of $SbCl_3$ in HClAq, under special conditions, a lustrous silver-like deposit is obtained on the negative electrode; this deposit when dry explodes when rubbed with a hard substance, or when heated to 200°, with formation of clouds of $SbCl_3$; a similar change occurs when the deposit is heated under water to 75°, but at ordinary temperatures it may be rubbed with a hard body under water without change. This so called *explosive antimony* contains $SbCl_3$ varying from 8 to 20 p.c. A similar explosive substance is obtained by electrolysing $SbBr_3$ in HBrAq, or SbI_3 in HIAq; the former contains 18 to 20 p.c. $SbBr_3$, it explodes at 160°; the latter contains 22 p.c. HI and also SbI_3, it explodes at 160° (Gore, *Pr.* 9, 70 and 304; *ibid. C. J.* [2] 1, 365; Böttger, *J. pr.* 73, 484; 107, 43). According to Böttger (*C. C.* 1875. 674) *explosive antimony* also contains occluded hydrogen.

The atomic weight of Sb has been determined (i.) by analysing and determining V.D. of certain gaseous compounds, particularly $SbCl_3$ and $Sb(CH_3)_3$; (ii.) by measuring the S.H. of Sb; (iii.) by comparing isomorphous compounds of Sb, As, and Bi; (iv.) by analyses of Sb_2S_3 (Schneider, *P.* 98, 293), $SbCl_3$ (Weber, *P.* 98, 455; Dexter, *P.* 100, 563; Dumas, *C. R.* 46, 951; Kessler, *P.* 95, 204, 113, 134), $SbBr_3$ and SbI_3, and by synthesis of Sb_2S_3 (Cooke, *P. Am. A.* [2] 5, 1; 7, 251; 9, 1; *B.* 13, 951) (*comp.* also Kessler, *B.* 12, 1044; Schneider, *J. pr.* [2] 22, 131; and Bongartz, *B.* 16, 1942). Some of the earlier determinations gave the number 122; but the researches of Cooke have established the value 120. The atom of Sb is trivalent in gaseous molecules, $SbCl_3$, $Sb(CH_3)_3$. Antimony combines with oxygen and chlorine with production of heat: $[Sb^2,O^3,3H^2O]=167,420$, $[Sb^2, O^5, 3H^2O]=228,780$, $[Sb, Cl^3]=91,390$, $[Sb, Cl^5]=104,870$ (*Th.* 2, 240). Antimony is oxidised by strong HNO_3, or by heating with various metallic oxides, *e.g.* MnO_2, PbO_2; hot conc. H_2SO_4 forms $Sb_2.3SO_4$; Sb combines with Cl or Br with production of light. Pure Sb is unacted on by HClAq out of contact with air; in presence of a little HNO_3Aq solution proceeds rapidly (Cooke, *P. Am. A.* [2] 5, 1). Antimony forms three oxides Sb_4O_6, Sb_2O_4, and Sb_2O_5; various compounds corresponding to the first and third are known. Antimony is more metallic than arsenic, whether considered physically or chemically. Hydrated antimonious oxide, $Sb_2O_3.3H_2O(=Sb(OH)_3)$, is known, and reacts as a feeble base; if one-third part of the H is replaced by K the remaining OH groups may be replaced by the residue of tartaric acid, with formation of $Sb.OK.C_4H_4O_6$ (*v.* ANTIMONIOUS OXIDE, *Reactions*, No. 4). Various compounds of Sb_2O_3 with SO_3 (*v.* ANTIMONIOUS OXIDE, *Reactions*, No. 3), and at least one with N_2O_5 are known. A few unstable salts derived from the hypothetical hydrate SbO.OH $(=Sb_2O_3.H_2O)$ are known, so that Sb_2O_3 acts both towards strong acids and strong alkalis as a feeble salt-forming oxide: thus $[2HClAq, 2Sb^2O^3Aq]=4,720$; whereas $[2HClAq, 2Na^2OAq]=25,500$ (*Th.* 2, 241). The thio-antimonites are few in number and their stability is decidedly less than that of the thio-arsenites. The compounds of Sb which most decidedly exhibit negative or acidic functions are Sb_2O_5 and Sb_2S_5; the same holds good for As. The haloid compounds of Sb form many well-marked double salts. Many oxyhaloid compounds are also known. SbH_3 does not combine with acids, but compounds of the type SbR_4X where $R=C_nH_{2n+1}$, and X is a halogen or even OH, have been prepared (*v.* ANTIMONY, COMPOUNDS WITH ORGANIC RADICLES). For further discussion of the chemical relations of Sb, *v.* BISMUTH, CHEMICAL RELATIONS OF; and NITROGEN GROUP OF ELEMENTS.

Reactions.—1. *Water* is not decomposed at ordinary temperatures by Sb; but at a red heat it reacts with steam to produce oxide of Sb and H.—2. Dilute *nitric acid* digested with finely powdered Sb forms a compound of Sb_4O_6 with N_2O_5; stronger acid forms chiefly $Sb_2O_5.xH_2O$ and Sb_2O_4.—3. *Sulphuric acid* reacts with Sb only when conc. and hot; SO_2 is evolved, and a compound, or compounds, of Sb_2O_3 with SO_3 produced.—4. By the action of aqueous *sulphurous acid* at 200° in a closed tube Sb_2S_3 is produced. 5. *Hydrochloric acid* forms $SbCl_3$ when heated with powdered Sb; in absence of air no action occurs (Cooke, *P. Am. A.* [2] 5, 1).—6. *Aqua regia* dissolves Sb forming $SbCl_5$.—7. *Solid phosphoric acid* and carbon heated with Sb form phosphide of Sb.—8. *Alkali nitrates and chlorates* heated with Sb form alkali antimonates and generally also Sb_2O_3.—9. *Alkali sulphates* form Sb_2S_3, alkali sulphide, alkali antimonate, and Sb_2O_3.

Combinations. — 1. With *nascent hydrogen* SbH_3 is formed (*q. v.*). — 2. With *chlorine*, *bromine*, or *iodine*, the compounds $SbCl_3$ and $SbCl_5$, $SbBr_3$, and SbI_3 are produced (*q. v.*).—3. With *fluorine* (action of HFAq on Sb_4O_6 and $Sb_2O_5.3H_2O$) SbF_3 and SbF_5 are formed (*q. v.*).—4. Sb combines with *oxygen* to form Sb_4O_6 and Sb_2O_4 (*q. v.*); Sb_2O_5 (*q. v.*) is produced by the action of conc. HNO_3.—5. The sulphide Sb_2S_3 (*q. v.*) may be obtained by heating Sb with *sulphur*; the pentasulphide Sb_2S_5 (*q. v.*) is best produced by decomposing Na_3SbS_4 by an acid.—6. Heated with *selenion* Sb_2Se_3 is formed as a greyish metal-like solid (Berzelius; also Hofacker, *A.* 107, 6; *v.* also Uelsmann, *A.* 116, 124). Sb_2Se_3 fused with Se and an alkali forms alkali seleno-antimonate (*e.g.* Na_3SbSe_4); this compound is decomposed by acids, in absence of air, with ppn. of brown Sb_2Se_5. (Hofacker, *l.c.*). — 7. With *tellurium* (Oppenheim, *J. pr.* 71, 277) Sb forms either iron-grey SbTe, or tin-white Sb_2Te_3 (S.G. of latter $\underline{13^\circ}=6{\cdot}47\text{–}6{\cdot}51$; Bödeker a. Giesecke). — 8. *Phosphorus* is said to combine with Sb to form a tin-white brittle phosphide containing 15·5 p.c. P (Landgrebe, *S.* 53, 469). By the action of P (in CS_2) on $SbBr_3$ (in CS_2) a red powder, PSb, is obtained (Macivor, *B.* 6, 1362).—9. Sb combines with *arsenic*, by fusion under boric acid, to form crystalline Sb_2As (Descampes, *C. R.* 86, 1065). The compound Sb_2As_3 occurs native as *allamontite.* — 10. *Antimony* forms *alloys* with many *metals*; they are usually produced by melting together Sb and the specified metal. The alloys with K and Na are produced by fusing Sb with K_2CO_3 (or Na_2CO_3) and C, or by reducing Sb_4O_6 with $KH.C_4H_4O_6$ at high temperatures; they decompose water with evolution of H and separation of Sb; if containing much K or Na they take fire in the air. The alloys of Sb are usually lustrous, hard, and brittle. The alloys with Cu and Sn will be described under those metals. An alloy of *iron* is formed when Sb_2S_3 is reduced with excess of Fe; a mixture of 7 parts Sb and 3 parts Fe heated to whiteness in a charcoal-lined crucible produces a very hard white alloy. *Gold* loses its malleability by the presence of about $\frac{1}{2000}$ of Sb. *Lead* alloys with Sb in all proportions; the lead is hardened; type metal is an alloy of about

17–20 parts Sb with lead and sometimes Bi or Sn (*v.* Lead, alloys of). With *nickel* two alloys are known; NiSb sublimes in prisms; Ni_2Sb occurs as *breithauptite* containing a little Fe and PbS. Two alloys with *silver*, Ag_4Sb and Ag_6Sb, occur native as *antimonial silver*. With *zinc* at least two crystalline alloys of definite composition are known, $SbZn_3$ and $SbZn_2$ (Cooke, *Am. S.* [2] 18, 229; 20, 222).

Many of these alloys are used in manufactures. Antimony compounds are also used in medicine.

Detection.—Most Sb compounds are insoluble in water and in excess of conc. HNO_3Aq, but many dissolve in HClAq, especially if tartaric acid is added; insoluble compounds may be dissolved by fusion with KNO_3 and K_2CO_3 and treatment with HClAq; when Sb compounds are fused with $NaNO_3$ and Na_2CO_3, $NaSbO_3$, insoluble in water, is formed.

In dry way. Heated on charcoal with Na_2CO_3 and KCN, all Sb compounds yield a brittle lustrous metallic bead. In the upper reduction-flame of the Bunsen lamp, Sb compounds give a green colour to the flame; in the oxidation-flame, a white oxide film is obtained (on porcelain) which, moistened with neutral $AgNO_3Aq$ and then blown on with ammoniacal air, gives a black spot (Ag_4O).

In wet way. I. *Antimonious compounds.* (i.) *Sulphuretted hydrogen* pps. orange-red Sb_2S_3 from acidulated solutions, soluble in KOHAq or NaOHAq, less soluble in NH_3Aq, insoluble in NH_4HCO_3Aq, soluble in K_2SAq and $(NH_4)_2SAq$, insoluble in dilute acids, but dissolved by boiling with conc. HClAq. Dilute tartar emetic solution is not ppd. by H_2S, the liquid turns red; conc. solutions are completely ppd. (Schulze, *J. pr.* [2] 27, 320). (ii.) Heated with *gold chloride* solution in presence of HClAq, Au is ppd. along with Sb_2O_5. (iii.) *Caustic and carbonated alkalis* pp. white Sb_4O_6 soluble in KOHAq and NaOHAq; the ppn. is slow and incomplete in presence of tartaric acid. (iv.) *Zinc* pps. Sb as a black powder; in presence of acids and Pt the Sb is deposited on the Pt, and a little SbH_3 is also formed; the deposited Sb is insoluble in cold HClAq, but easily dissolves in HNO_3Aq. (v.) *Zinc and iron powder*, added to a solution of an antimonious compound in conc. NH_4ClAq containing NH_3Aq, ppt. Sb on the Zn without production of any SbH_3; under similar conditions arsenious compounds yield AsH_3. (vi.) *Zinc and dilute H_2SO_4Aq*, in absence of HNO_3Aq, evolve H, mixed with SbH_3, which may be burnt in air with production of Sb_2O_3, or decomposed by heat into Sb and H, or led into $AgNO_3Aq$ whereby silver antimonide is ppd. mixed with Ag, or passed over S in sunshine whereby orange Sb_2S_3 is formed (*v.* Jones, *C. J.* [2] 14, 649; this is a very delicate test; *v.* Marsh's test for arsenic, under Arsenic, Detection of). (vii.) Dissolved in KOHAq, and treated with *silver nitrate*, a brown black pp. is obtained, from which NH_3Aq removes Ag_2O, leaving black Ag_4O.

II. *Antimonic compounds.*—(i.) *Sulphuretted hydrogen* pps. orange-red Sb_2S_5 from acidulated solutions, soluble in KOHAq, in K_2CO_3Aq, in $(NH_4)_2SAq$, and more slowly in NH_3Aq. (ii.) Heated with *hydrochloric acid and potassium iodide*, SbI_3 and I are formed ($Sb_2O_5 + 10KIAq = 2SbI_3Aq + 5K_2OAq + 4I$). As antimony trioxide has no action on KI, this reaction may be used to detect Sb_2O_5 in Sb_2O_3. (iii.) *Gold salts*, *chromates*, and *permanganates*, are *not* reduced by antimonic compounds; nor is $AgNO_3Aq$ acted on (compare tests (ii.) and (vii.) for antimonious compounds). (iv.) Towards *zinc*, or *iron, and acids*, antimonic compounds behave similarly to antimonious (*v.* Antimonoso-antimonic oxide). Antimony tetroxide Sb_2O_4 gives the reactions both of Sb_2O_3 and Sb_2O_5; an alkaline solution reduces $AgNO_3Aq$ and $AuCl_3Aq$ slowly.

(For details of procedure in cases of suspected poisoning by Sb compounds a manual of toxicology must be consulted, *e.g.* Taylor *On Poisons*, or Taylor's *Medical Jurisprudence*.)

Antimony may be separated (qualitatively) from tin and arsenic by treating the sulphides with conc. $(NH_4)HCO_3Aq$, which dissolves only As_2S_3, then dissolving the SnS (or SnS_2) and Sb_2S_3 in conc. HClAq, boiling off H_2S, ppg. Sb in one portion by Zn, reducing $SnCl_4$ to $SnCl_2$ in another portion by boiling with Cu turnings, and ppg. by $HgCl_2Aq$; or the solution containing $SbCl_3$ and $SnCl_4$ may be diluted and boiled with a slight excess of iron wire whereby Sb is ppd. and $SnCl_4$ is reduced to $SnCl_2$ (Classen, *J. pr.* 93, 477). Sb_2S_3 is completely converted into $SbCl_3$ by dry HCl at ordinary temperatures, whereas SnS is unacted on (Tookey, *J. pr.* 88, 435). A little As in Sb compounds may be detected by fusing with 2 pts. Na_2CO_3 and 4 pts. $NaNO_3$, and dissolving in water, Na_3AsO_4 goes into solution and $NaSbO_3$ remains.

Estimation.—I. Gravimetric methods. Antimonious compounds are ppd. by H_2S in presence of HClAq and tartaric acid, excess of H_2S is removed by CO_2, the pp. of Sb_2S_3 is collected (after boiling for 15–20 mins.; Sharples, *Fr.* 10, 343), on a weighed filter, dried at 100° and weighed; a portion is then dried by heating in a stream of dry CO_2 and again weighed; if a portion of the pp. dried at 100° yields S on treatment with hot conc. HClAq, the pp. contains Sb_2S_5 or free S; in this case the other portion must be heated in dry CO_2 until S is no longer volatilised; the residue is now pure Sb_2S_3 (*v.* also Cooke, *P. Am. A.* 13, 1; 17, 13). Or the pp. of Sb_2S_3 (perhaps mixed with Sb_2S_5 and S) may be converted into Sb_2O_4 by treatment with conc. HNO_3Aq (for details *v.* Bunsen, *A.* 106, 3). Schneider (*P.* 110, 634) decomposes the Sb_2S_3 by HClAq, leads the H_2S into an alkaline solution and determines it by volumetric methods (iodine method, or ppn. by excess of titrated As_2O_3Aq and determination of excess of As_2O_3 by iodine).

II. Volumetric methods. (i.) Antimonious compounds are oxidised to antimonic by iodine in alkaline solutions ($Sb_2O_3 + 4I + 2H_2O = Sb_2O_5 + 4HI$). $NaHCO_3Aq$ is the best alkaline solution; titrated I solution is run in until a blue colour is produced with starch. (ii.) Antimonious compounds are oxidised to antimonic in presence of tartaric acid, by $K_2Mn_2O_8$ solution (attention must be paid to details, *v.* Guyard, *Bl.* 6, 89). For other methods of estimating Sb, especially in presence of As, or of As and Sn *v.* Bunsen, *A.* 106, 3; 192, 317; Clarke, *Am. S.* [2] 49, 48.

References.—**In addition to those in the text,**

the following older memoirs are important:—Bergmann, *Opusc.* 3, 164; Thénard, *A. Ch.* 32, 257; Proust, *G. A.* 25, 186; Berzelius, *S.* 6, 144; 22, 69; 34, 58; *P.* 20, 365; 37, 163; Berthier, *A. Ch.* [2] 22, 239; 25, 379; H. Rose, *P.* 8, 441; 42, 532; 24, 165; Vauquelin, *S.* 21, 219.

Antimony, acids of, and their salts (compare arts. ACIDS; ACIDS, BASICITY OF; HYDROXIDES). The oxides Sb_2O_4 and Sb_2O_5 are scarcely soluble in water, but each reddens moist blue litmus paper; the oxide Sb_4O_6 is slightly soluble in water, but is without action on litmus. A few feebly marked salts are known which may be regarded as derived from the hypothetical hydrate $Sb_2O_3.H_2O$ ($=SbO.OH$); two sodium salts, so-called *antimonites*, are obtained according to Terreil (*A. Ch.* [4] 7, 380) by dissolving Sb_4O_6 in boiling NaOHAq and allowing to cool (*v. infra*). Two hydrates of Sb_4O_6, viz. $Sb_4O_6.4H_2O$ and $Sb_4O_6.6H_2O$ have been obtained (*v.* ANTIMONIOUS OXIDE); but neither seems to possess acidic properties. The oxide Sb_4O_6 reacts with Na_2CO_3 when the two are fused together, but on adding water Sb_4O_6 is ppd. and NaOH remains in solution. The acid-forming character of Sb_4O_6 is therefore extremely feeble (*v.* further ANTIMONIOUS OXIDE).

No hydrate of Sb_2O_4 is known; but by fusing this oxide with KOH or K_2CO_3, a compound, $Sb_2O_4.K_2O$, insoluble in cold water, is produced; by dissolving this in hot water and adding various metallic compounds, several compounds of Sb_2O_4 with metallic oxides, *e.g.* Sb_2O_4 CaO and $Sb_2O_4.CuO$ (which both occur native as *romeïte* and *ammiolite* respectively [? merely mixtures]) are obtained. A solution of Sb_2O_4 in KOHAq (obtained by fusion) is easily decomposed: *e.g.* on boiling and then diluting, Sb_2O_3 is ppd. and $Sb_2O_5.xH_2O$ is then thrown down on addition of acids; on standing in air, without boiling, $KSbO_3$ is produced. The oxide Sb_2O_4 cannot therefore be regarded as a definite anhydride, nor can any acid, or well-marked series of salts, be said to exist corresponding with this oxide (*v.* ANTIMONY, OXIDES OF).

Three hydrates of antimonic oxide are known (*v. infra*): $Sb_2O_5.H_2O$ ($=HSbO_3$), $Sb_2O_5.2H_2O$ ($=H_4Sb_2O_7$), and $Sb_2O_5.3H_2O$ ($=H_3SbO_4$). The first and third may be obtained from $H_4Sb_2O_7.2H_2O$ which is a product of the action of water on $SbCl_5$; dried over H_2SO_4, H_3SbO_4 is obtained, and at higher temperatures $HSbO_3$ is produced (*v.* ANTIMONATES). Several fairly marked salts are known, *antimonates*, derived from $HSbO_3$; two series of *metantimonates* (M_4Sb_2O. and $M_2H_2Sb_2O_7$) exist (*v. infra*); no salts of the hydrate $Sb_2O_5.3H_2O$ ($=H_3SbO_4$) have been obtained. Antimonates are usually obtained by fusion; aqueous alkalis dissolve the hydrate $Sb_2O_5.H_2O$ without change; some metantimonates are produced from the hydrate $Sb_2O_5.2H_2O$ by the action of alkalis in the wet way. Antimonic oxide is evidently a feebly marked acid-forming oxide. The only definite compounds of Sb hitherto obtained which exhibit acidic characters are then $HSbO_3$ and $H_4Sb_2O_7$.

The following thermal data are given by Thomsen $[Sb^2, O^3, 3H^2O] = 167,420$; $[Sb, O^2, H, H^2O] = 117,890$; $[Sb^2, O^5, 3H^2O] = 228,780$; $[Sb, O^3, H, H^2O] = 145,570$; $[SbO^3H^3, O] = 30,680$.

I. ANTIMONITES.—Two sodium salts are described by Terreil (*A. Ch.* [4] 7, 380): $NaSbO_2.3H_2O$, lustrous octahedral crystals, obtained by dissolving Sb_2O_3 in boiling NaOHAq and allowing to cool; $NaSbO_2.Sb_2O_3.H_2O$. large crystals, insoluble in water, obtained from very concentrated alkaline solutions.

II. ANTIMONOSO-ANTIMONATES.—This name has been given to the compounds of Sb_2O_4 with metallic oxides; it implies that these bodies are compounds of antimonites with antimonates; very little, however, is known of their properties. Two potassium salts $K_2O.Sb_2O_4$ ($?KSbO_3.KSbO_2$), and $K_2O.2Sb_2O_4$ are said to be produced, the former by fusing Sb_2O_4 with KOH or K_2CO_3 and washing with cold water, the latter by the action of a little HClAq on the former. An aqueous solution (the salt dissolves in hot water) of $K_2O.Sb_2O_4$ is said to give pps. with various metallic salts. These salts might perhaps be regarded as derivatives of the hypothetical hydrates $Sb_2O_4.H_2O$ ($=H_2Sb_2O_5$) and $2Sb_2O_4.H_2O$ ($=H_2Sb_4O_9$); but our knowledge of them is almost nil.

III. ANTIMONATES, AND ANTIMONIC ACIDS.—Three hydrates of Sb_2O_5 are known. By ppg. $KSbO_3Aq$ by HNO_3Aq, washing the pp. and leaving it for a whole summer, Geuther obtained the hydrate $Sb_2O_5.3H_2O$ ($=H_3SbO_4$) (*J. pr.* [2] 4, 438): at 175° this hydrate gives $HSbO_3$ ($=Sb_2O_5.H_2O$). The hydrate $Sb_2O_5.2H_2O$ ($=H_4Sb_2O_7$) is obtained by adding hot water to $SbCl_5$, and drying the pp. of $H_4Sb_2O_7.2H_2O$ at 100°; it is also produced by decomposing the salts $M_4Sb_2O_7$ by acids: this hydrate is easily decomposed to $HSbO_3$, even by standing in contact with water (Dubrawa, *A.* 186. 110; Conrad, *C. N.* 40, 197). $HSbO_3$ may also be obtained by decomposing $MSbO_3$ by acids, or by oxidising Sb by HNO_3. The hydrate $HSbO_3$ is slightly soluble in water, insoluble in NH_3Aq, and easily soluble in KOHAq; $H_4Sb_2O_7$ is more soluble in water, and dissolves in both NH_3Aq and KOHAq: little is known of the hydrate $Sb_2O_5.3H_2O$. The antimonates belong to the two types $MSbO_3$, and $M_4Sb_2O_7$; the former are usually called antimonates, the latter metantimonates.

Antimonates: investigated by Berzelius, then by Fremy (*A. Ch.* [3] 12, 499; 22, 404), and by Heffter (*P.* 86, 418; 98, 293). These salts are obtained by fusing Sb or Sb_2O_3 with nitrates, or $HSbO_3$ with carbonates, or by double decomposition from the K salts; aqueous alkalis dissolve $HSbO_3$ without change. Some of the K and NH_4 salts are soluble in water, the others are slightly soluble or insoluble. The normal antimonates are converted into acid salts by the action of weak acids (*e.g.* CO_2Aq), they are decomposed by stronger acids with separation of $HSbO_3$; the antimonates are decomposed by fusion with NH_4Cl, the whole of the Sb being volatilised as $SbCl_3$; those which are soluble in water or acids are decomposed by $(NH_4)_2SAq$ with production of thio-antimonates.

Ammonium antimonate $NH_4SbO_3.2H_2O$; white crystalline powder, insoluble in water, easily decomposed with loss of NH_3: obtained by dissolving $HSbO_3$ in warm NH_3Aq.

Barium antimonate $Ba(SbO_3)_2$; obtained by adding $BaCl_2Aq$ to $KSbO_3Aq$; pp. at first is flocculent but becomes crystalline. By adding $BaCl_2Aq$ to boiling $NaSbO_3Aq$ a flocculent pp. of $Ba(SbO_3)_2.5H_2O$ (air-dried) is obtained.

Potassium antimonates.—The normal salt $KSbO_3$ is obtained by fusing 1 part Sb with 4 parts KNO_3, and washing with hot water; it dissolves after long boiling with water, and is obtained as a mass of white crystals when the solution is evaporated until a crust forms. Another form of this salt is described by Fremy as a gummy mass, obtained by evaporating the foregoing solution nearly to dryness, or more easily by long-continued fusion, either alone or with KOH or K_2CO_3, of the product obtained by melting together 1 part Sb and 4 parts KNO_3. The gum-like salt dried in vacuo is $2KSbO_3.5H_2O$, it is easily soluble in hot water; dried at 160° it leaves $2KSbO_3.3H_2O$ which is changed to the gum-like salt by boiling with water; at a red heat all the water is removed, and the product is gradually changed to the gum-like salt by contact with hot water. When the normal salt is boiled with water, a residue of $2KSbO_3.Sb_2O_5.10H_2O$ is obtained; and a similar salt with $6H_2O$ is produced by the action of CO_2 on the normal salt (Heffter, *P.* 86, 418; *v.* also v. Knorre a. Olschewsky, *B.* 18, 2353).

Sodium antimonates. — The salt $2NaSbO_3.7H_2O$ is obtained similarly to the normal $KSbO_3$; also in octahedra by the action of NaOHAq on Sb_2S_5. $NaSbO_3.3H_2O$ is said to be formed by the action of NaOHAq on Sb_2S_3, filtration, and addition of more NaOHAq (*v.* also v. Knorre a. Olschewsky, *B.* 18, 2353).

Many other antimonates are described by Fremy and Heffter; the chief are the salts $Ca(SbO_3)_2$, $Co(SbO_3)_2$, $Cu(SbO_3)_2.5H_2O$, $Pb(SbO_3)_2$, $LiSbO_3$, $Mg.2SbO_3.12H_2O$, $Hg(SbO_3)_2$, $Sr(SbO_3)_2.6H_2O$, $Sn(SbO_3)_2.2H_2O$ (*v.* also Schiff, *A.* 120, 47; Unger, *Ar. Ph.* [2] 147, 195).

Metantimonates. These salts fall into two classes—normal salts $M_4Sb_2O_7$, and acid salts $M_2H_2Sb_2O_7$; they are formed from the antimonates by addition of metallic oxide or water ($2MSbO_3 + M_2O = M_4Sb_2O_7$; and $2MSbO_3 + H_2O = M_2H_2Sb_2O_7$); conversely the metantimonates lose M_2O (or H_2O) and form $MSbO_3$. The metantimonates as a class are insoluble in water, the alkali salts are crystalline; they are decomposed by acids; they have been chiefly investigated by Fremy (*A. Ch.* [3] 12, 499).

Ammonium metantimonates.—$H_4Sb_2O_7$ dissolves slowly in cold NH_3Aq; a conc. solution on addition of alcohol gives the acid salt $(NH_4)_2H_2Sb_2O_7.5H_2O$; this salt is easily decomposed by heating, either in presence or absence of water, into $(NH_4)SbO_3$. The normal salt has not yet been isolated.

Potassium metantimonates.—By fusing $KSbO_3$ (best the gum-like salt) with about 3 parts KOH, dissolving in water, and crystallising, the salt $K_4Sb_2O_7$ is obtained as deliquescent, easily soluble, crystals. The acid salt $K_2H_2Sb_2O_7.6H_2O$ is produced by decomposing the normal salt by a little water (KOHAq is also produced), or by dissolving $SbCl_3$ in excess of KOHAq, oxidising by $K_2Mn_2O_8Aq$, and crystallising (Reynoso, *A. Ch.* [3] 23, 325); at 200° the dehydrated salt $K_2H_2Sb_2O_7$ is obtained, and at 300° $KSbO_3$ is formed. The acid salt is slightly soluble in cold water, more easily in water at 40°–50°, with gradual production of the gum-like $KSbO_3$; an aqueous solution of this salt precipitates sodium salts. Other metantimonates are described by Fremy (*l.c.*).

Seleno-antimonates.—A few salts are known, derived from the hypothetical selenoantimonic acid H_3SbSe_4. $Na_3SbSe_4.9H_2O$ forms orange-red tetrahedral crystals, and is obtained by fusing Na_2CO_3, Sb_2Se_3, Se, and C; the salt $Na_3SbS_3Se.9H_2O$ is obtained as yellow tetrahedral crystals by boiling Na_3SbS_4Aq with Se (Hofacker, *A.* 107, 6).

Antimony, alloys of, *v.* ANTIMONY, *Combinations*, No. 10.

Antimony, arsenide of, *v.* ANTIMONY, *Combinations*, No. 9.

Antimony, bromide of. $SbBr_3$. No other bromide is known. Mol. w. 359·28; [90°–94°] (Serullas, *P.* 14, 112). (275°–280°) (Kopp, *A.* 94, 257; Cooke, *P. Am. A.* [2] 5, 72). V.D. 180 (Worcester, *P. Am. A.* [2] 10, 61). S.G. $^{23^\circ}$ 4·148 (Cooke, *l.c.*); fused $\frac{90^\circ}{0}$ 3·641 (Kopp, *l.c.*). If the vol. of fused $SbBr_3 = 1$ for $d^\circ = 0^\circ$, then the vol. at $t^\circ = 1 + \cdot000576d + \cdot0000013465d^2$, where $d = t^\circ - 90^\circ$ (Kopp, *l.c.*). H.F. solid Sb, gaseous Br,$[Sb,Br^3] = 76,900$ (Guntz, *C. R.* 101, 161).

Formation.—1. By shaking powdered Sb into a retort containing Br and connected with a condenser.—2. By distilling a mixture of Sb sulphate and KBr (Macivor, *C. N.* 29, 179).

Preparation.—1. By adding powdered Sb to a solution of Br in dry CS_2 at 0°, distilling off CS_2, adding powdered Sb, distilling off the $SbBr_3$ and recrystallising it from CS_2 (Cooke, *P. Am. A.* [2] 5, 72; Nicklès, *C. R.* 48, 837).

Properties and *Reactions.*—Deliquescent trimetric crystals; $a:b:c = 1{\cdot}224:1:1{\cdot}064$ (Cooke, *l.c.*); sublimes when heated. Decomposed by water; cold water produces $Sb_4O_5Br_2$, hot water $10Sb_4O_5Br_2.SbBr_3$ (Macivor, *C. N.* 29, 179). The compound $Sb_4O_5Br_2$ is also produced by heating $SbBr_3$ with alcohol to 160° (Macivor, *l.c.*). The action of air and sunlight on $SbBr_3$ in CS_2 produces an oxybromide, probably SbOBr (Cooke, *P. Am. A.* [2] 5, 72). Combines with KCl to form $SbBr_3.3KCl$, which according to Atkinson is identical with $SbCl_3.3KBr$ obtained by action of $SbCl_3$ on KBr in presence of a little water (*C. J.* 43, 290).

Antimony, chlorides of. Sb and Cl combine directly to form two compounds $SbCl_3$ and $SbCl_5$; the former may be gasified, the latter is decomposed by heat at ordinary pressures into $SbCl_3 + Cl_2$ (*v. infra*).

I. ANTIMONIOUS CHLORIDE. $SbCl_3$. Mol. w. 226·11. [73°·2] (Thorpe, *C. J.* 37, 387). (223·5°) (216°, Cooke, *P. Am. A.* [2] 5, 72). S.G. $\frac{73^\circ}{4}$ 2·6753 (Thorpe, *l.c.*). S.G. 3·064 (Cooke, *P. Am. A.* [2] 5, 72). V.D. 115·6. $V = 1 + \cdot0008054d + \cdot00001032d^2$, where $d =$ degrees above M.P. (73·2°) (Thorpe, *l.c.*). $[Sb,Cl^3] = 91,390$ (Thomsen).

Formation.—1. By dissolving Sb, Sb_2O_3, or Sb_2S_3, in HClAq with a little HNO_3Aq, evaporating, and then distilling.—2. By the action of Cl on Sb_2S_3.—3. By distilling together 1 part powdered Sb with 2 parts $HgCl_2$; or 3 parts Sb_2S_3 with 7 parts $HgCl_2$; or 1 part $Sb_2(SO_4)_3$ with 2 parts dry NaCl.—4. By distilling 2 parts Sb_2O_3 (impure), with 6 parts dry NaCl, 4 parts H_2SO_4, and 2 parts H_2O and changing the

receiver as soon as the distillate begins to solidify on cooling.

Preparation.—1. By passing dry Cl into a retort containing powdered Sb, until most of the Sb is transformed into $SbCl_3$; a little more Sb is then added, the stream of Cl is stopped, and the $SbCl_3$ is distilled off into a dry receiver. Cooke (*P. Am. A.* [2] 5, 72) saturates warm CS_2 with $SbCl_3$ and cools by freezing mixture. A solution of $SbCl_3$ in conc. HClAq (generally prepared by the action of the acid on Sb_2S_3) is used in pharmacy.

Properties.—A colourless, translucent, crystalline, mass. Melted and allowed partially to solidify, or dissolved in hot CS_2 and cooled, trimetric crystals are obtained, $a:b:c =$ 1·263:1:1·09 (Cooke, *P. Am. A.* [2] 5, 72). Very caustic. Soluble in alcohol without change; on heating this solution oxychlorides of Sb (*q.v.*), HCl, and C_2H_5Cl, are formed. It absorbs moisture from the air and forms a clear liquid, from which crystals of $SbCl_3$ are obtained by standing over H_2SO_4.

Reactions.—1. With *water* various oxychlorides are produced ($SbCl_3$ dissolves unchanged in a very little water at ordinary temperatures); if a little cold water is added (about 2 parts to 1 part $SbCl_3$), and the pp. is washed with ether, SbOCl (*q. v.*) is obtained (Peligot, *A.* 64, 280; Sabanajew, *Bl.* [2] 16, 79). When from 5 to 50 parts H_2O are added to 1 part $SbCl_3$, the compound $Sb_4O_5Cl_2$ (*q. v.*) is obtained (Sabanajew, *l.c.*). Other observations point to a varying composition for the product of the mutual action of $SbCl_3$ and H_2O; by continued washing the whole of the Cl may be removed (*v.* Duflos, *S.* 67, 268; Johnston, *J. pr.* 6, 55; Malaguti, *J. pr.* 6, 253; Peligot, *A.* 64, 280; Schneider, *P.* 108, 407; Schäffer, *A.* 152, 314). Thomsen (*Th.* 2, 240) gives these data: $[SbCl^3, Aq] = 8{,}910$ when $Sb_4O_5Cl_2$ is formed, and $= 7{,}730$ when Sb_2O_3Aq and HClAq are formed. According to Williams (*C. N.* 24, 225) boiling water produces $10Sb_4Cl_2O_5.SbCl_3$. Formation of oxychlorides is prevented by tartaric acid.—2. *Antimonious oxide* dissolves in boiling $SbCl_3$ to form oxychlorides; $SbOCl.7SbCl_3$ is described by Schneider (*P.* 108, 407).—3. *Alcohol* heated with $SbCl_3$ in proportion $C_2H_6O:SbCl_3$ in a closed tube to 160° forms SbOCl; heated to 140° in the proportion $3C_2H_6O:SbCl_3$, $Sb_4O_5Cl_2$ is formed (Schäffer, *A.* 152, 314).—4. Aqueous solution of *sodium thiosulphate* reacts on solution of $SbCl_3$ to form a double compound of Sb_2O_3 and Sb_2S_3, probably $Sb_2O_3.Sb_2S_3$ (*v.* ANTIMONY, OXYSULPHIDES OF).—5. Boiling $SbCl_3$ dissolves powdered antimony trisulphide, on cooling a crystalline mass of sulphochloride, $SbSCl.7SbCl_3$, is obtained; on washing with alcohol $2SbSCl.3Sb_2S_3$ remains (Schneider, *P.* 108, 407).

Combinations.—1. With *chlorine*, $SbCl_5$ is formed.—2. *Ammonia* forms $SbCl_3.NH_3$ which on warming gives off all its NH_3.—3. By mixing conc. solutions of $SbCl_3$ and *alkaline chlorides* and evaporating, double salts are formed, *e.g.* $2NH_4Cl.SbCl_3$; $2(BaCl_2.SbCl_3).3H_2O$; $3KCl.SbCl_3$; $3NaCl.SbCl_3$. With KBr the salt $SbCl_3.3KBr$ is formed identical with $SbBr_3.3KCl$ obtained by the action of KClAq on $SbBr_3$ (Atkinson, *C. J.* 43, 290).

II. ANTIMONIC CHLORIDE $SbCl_5$. Mol. w. unknown; vapour obtained by heating consists of $SbCl_3 + Cl_2$. [−6°] (Kämmerer, *B.* 8, 507). S.G. $\frac{20^\circ}{20}$ 2·346 (Haagen, *P.* 131, 117). (79° at 22 mm.; 68° at 14 mm.) (Anschütz a. Evans, *C. J.* 49, 708).

Preparation.—Powdered Sb is heated in a retort in a rapid stream of dry Cl; $SbCl_3$ (and Cl) distils over, and $SbCl_5$ remains. Or melted $SbCl_3$ is saturated with Cl, and distilled in a stream of Cl (or under greatly diminished pressure, Anschütz a. Evans, *C. J.* 49, 708).

Properties.—Colourless, or slightly yellow, liquid, with an offensive smell, fuming in moist air; solidifies at a low temperature ($< -6^\circ$); absorbs moisture from air and changes to a crystalline mass. According to Anschütz a. Evans (*C. J.* 49, 708) $SbCl_5$ may be distilled unchanged at low pressures.

Reactions.—1. Dissolves in a very little *water*; solution over H_2SO_4 deposits crystals of $SbCl_5.4H_2O$. Kept cold by ice, and water added drop by drop in proportion $SbCl_5:H_2O$, $SbOCl_3$ (*q.v.*) is formed (Dubrawa, *A.* 184, 118). Addition of more water produces SbO_2Cl, which is decomposed by hot water, giving $H_4Sb_2O_7.2H_2O$, soluble in HClAq. Decomposition by H_2O hindered by tartaric acid. Thomsen (*Th.* 2, 242) gives the number $[SbCl^5, Aq] = 35{,}200$, when Sb_2O_5Aq and HClAq are formed.—2. Dry *sulphuretted hydrogen* produces white crystals of $SbSCl_3$, which are decomposed by heat into $SbCl_3$ and S_2Cl_2 (Cloez, *J. pr.* 51, 459).—3. Heated in closed tube to 140° with *antimonic oxide*, in proportion $3SbCl_5:Sb_2O_5$, Sb_3OCl_{13} and $Sb_3O_4Cl_7$ (*q. v.*) are produced (Williams, *C. J.* [2] 10, 122).—4. With *phosphorus trichloride* (in $CHCl_3$) reacts to form $PCl_5.SbCl_5$, and $SbCl_3$ (*v. Combinations*).—5. Chlorinates many *carbon compounds*, *e.g.* $CHCl_3$ to CCl_4, C_2H_4 to $C_2H_4Cl_2$, &c. (*v.* CHLORO-COMPOUNDS). 6. With *nitrogen tetroxide* forms $SbCl_5.NOCl$ (Weber, *P.* 123, 347).

Combinations.—1. With *ammonia* forms brown $SbCl_5.6NH_3$ which may be sublimed unchanged.—2. With *hydrocyanic acid* forms white crystals of $SbCl_5.3HCN$, which volatilise with partial decomposition under 100°, and are decomposed by H_2O (Klein, *A.* 74, 85).—3. With gaseous *cyanogen chloride* forms $SbCl_5.CNCl$ (Klein, *l.c.*).—4. Combines with some *non-metallic chlorides* to form double compounds which usually deliquesce in air and are decomposed by heat; the more important are $SbCl_5.PCl_5$ (Weber, *P.* 125, 78; Köhler, *B.* 13, 875); $SbCl_5.POCl_3$, $SbCl_5.SeCl_4$ and $SbCl_5.SCl_4$ (Weber, *l.c.*); and $SbCl_5.SeOCl_2$ (Weber, *P.* 125, 325).—5. Also combines with $C_6H_5PCl_4$ to form $SbCl_5.C_6H_5PCl_4$ (Köhler, *B.* 13, 1626).—6. Combines with various *alcohols*, and with *ether* (Williams, *C. J.* [2] 15, 463).

Antimony, fluorides of. Sb_2O_3 dissolves in HFAq to form SbF_3; $Sb_2O_5.xH_2O$ dissolves in HFAq to form SbF_5. Neither has been gasified, so that mol. ws. are unknown.

I. ANTIMONIOUS FLUORIDE SbF_3 [abt. 292°] (Carnelley, *C. J.* 33, 275).

Preparation.—(Berzelius, *P.* 1, 34; Dumas, *A. Ch.* [2] 31, 435; Flückiger, *A.* 84, 248).—1. By dissolving Sb_2O_3 in HFAq, evaporating at 70°–90° and crystallising.—2. By distilling Sb with HgF_2.

Properties.—White, trimetric, octahedral deliquescent, soluble in H_2O without decomposition.

Reactions.—1. Solution in *water* on evaporation yields an oxyfluoride (composition unknown).—2. *Deliquesced* SbF_3 pressed between paper gives $2SbF_3.Sb_2O_3$ ($=3SbOF.SbF_3$), which is decomposed by heating into SbF_3 and Sb_2O_3.

Combinations.— With *alkali fluorides* to form double compounds, SbF_3 combining with MF, 2MF, or 3MF, where M = K, Na, &c. These compounds are best obtained by dissolving Sb_2O_3 and M_2CO_3 in the proper proportions in HFAq, and evaporating. The principal compounds are $SbF_3.2NH_4F$; $SbF_3.2KF$, $SbF_3.KF$; $SbF_3.2LiF$; and $SbF_3.2NaF$ (*v.* Flückiger, *A.* 84, 248).

II. ANTIMONIC FLUORIDE, SbF_5. Obtained by Berzelius, investigated more fully by Marignac (*A.* 145, 239).

Preparation.—By dissolving hydrated Sb_2O_5 in HFAq, and evaporating.

Properties.—A gum-like amorphous mass, decomposed by heat; very slowly decomposed, in solution, by H_2S.

Combinations.—With the *alkali fluorides*, to form double compounds, which are easily soluble in water, crystallise badly, and yield oxyfluorides when evaporated in aqueous solutions, *e.g.* $SbOF_3.NaF$ from $SbF_5.2NaF$ (Marignac, *A.* 145, 239). These solutions are very slowly decomposed by H_2S, KOHAq, and K_2CO_3Aq. The more important compounds are $SbF_5.NH_4F$, $2(SbF_5.2NH_4F).H_2O$; $SbF_5.KF$, $SbF_5.2KF.2H_2O$; $SbF_5.NaF$.

Antimony, haloid compounds of. SbF_3, SbF_5; $SbCl_3$, $SbCl_5$; $SbBr_3$; SbI_3, (?SbI_5). Only $SbCl_3$ has been gasified and V.D. determined; $SbCl_5$ is decomposed by heat. The formulæ of the trihaloid salts are probably molecular, *v.* ANTIMONY, FLUORIDES OF, CHLORIDES OF, BROMIDES OF, IODIDES OF; *v.* also art. HALOID COMPOUNDS.

Antimony, hydride of (*v.* also art. HYDRIDES). SbH_3. (*Antimoniuretted hydrogen*; *Stibine*). Only one hydride of Sb, SbH_3, is certainly known; and this has not been obtained except mixed with much H. Marchand (*J. pr.* 31, 381) described a black powder obtained by electrolysing conc. NH_4ClAq with a rod of Sb as neg. and a thick Pt wire as pos. electrode. When a powerful battery was used, gas came off which burnt in the air; the powder was supposed to be a solid hydride of Sb, and the gas a spontaneously inflammable hydride (*v.* also Ruhland, *S.* 15, 418). But Marchand's results were not confirmed by Böttger (*J. pr.* 68, 372), who obtained only the ordinary products of the electrolysis of NH_4ClAq, viz. H, NH_3, and N chloride. Wiederhold (*C. C.* 1864. 995) described a graphite-like powder obtained by the action of dilute HClAq on an alloy of 1 part Sb with 5 parts Zn; after drying at 100° this powder gave off ·001 p.c. H at 200° (Sb_2H requires ·004). The gaseous hydride is almost certainly SbH_3 (*v.* especially Jones, *C. J.* [2] 14, 647), but it has not yet been obtained free from H.

Preparation.—By treating an alloy of 2 parts Zn and 1 part Sb (Capitaine, *B. J.* 20, 89), or 3 Zn and 2 Sb (Lassaigne, *B. J.* 22, 104), with dilute H_2SO_4Aq. Schiel (*A.* 104, 223) decomposes an alloy of Sb with K with dilute HClAq. Humpert (*C. C.* 1865. 863) treats conc. $SbCl_3Aq$ with Na amalgam. Jones obtained a gas containing about 4 p.c. SbH_3 by dropping conc. solution of $SbCl_3$ in conc. HClAq on to granulated Zn; the gas was partially decomposed as it was formed (*C. J.* [2] 14, 641).

Properties.—A colourless gas, with nauseating smell and intensely disagreeable taste, slightly soluble in H_2O but decomposed by long contact into Sb and H; easily decomposed by heat; burns in air to Sb_4O_6 and H_2O, or in limited supply of air to Sb, Sb_4O_6, and H_2O; decomposed by electric sparks into Sb and H. The gas obtained by reacting on an alloy of 2 parts Sb with 3 parts Zn with dilute H_2SO_4Aq, and collecting the first portions only, solidified at −91·5°, and decomposed, with separation of Sb, between −65° and −56° (Olszewski, *M.* 7, 371).

Reactions.—1. With *oxygen* and heat, explosion occurs and formation of Sb_4O_6 and H_2O; the same products are obtained by burning in air. — 2. Decomposed by *chlorine*, *bromine*, or *iodine*, with formation of $SbCl_3$, $SbBr_3$, or SbI_3; passed through a hot tube containing a little I, an orange-yellow or brown ring of SbI_3 is formed (Husson, *J. pr.* 106, 314).—3. Passed over *sulphur* in sunshine, or at temperatures over 100°, orange-coloured Sb_2S_3 is formed; very minute quantities of the gas may be thus detected ($2SbH_3 + 6S = Sb_2S_3 + 3H_2S$) (Jones, *C. J.* [2] 14, 649).—4. Decomposes *sulphuretted hydrogen* in sunshine forming Sb_2S_3 ($2SbH_3 + 3H_2S = Sb_2S_3 + 6H_2$) (Jones, *l.c.*).—5. With *antimonious chloride*, Sb and HCl are formed.—6. Easily oxidised by *nitric acid*.—7. Decomposed by *aqueous potash or soda* with separation of a black powder (? $SbOH_3$ or ? Sb_2O, *v.* Jones, *l.c.*; also Dragendorff, *Fr.* 5, 200) which is at once dissolved on shaking in air.—8. With aqueous *silver nitrate* the whole of the Sb is ppd. (as Ag_3Sb mixed with Ag, Lassaigne, *B. J.* 22, 104; *v.* also Jones, *l.c.*).

References. — Thompson, *B. J.* 18, 135; Pfaff, *P.* 40, 339; Simon, *P.* 42, 369; Vogel, *J. pr.* 13, 57; Meissner a. Hankel, *J. pr.* 25, 243.

Antimony, hydroxides of. Several compounds of Sb, H, and O are known; some of them are probably best regarded as hydrated oxides; others react as acids, especially $HSbO_3$ and $H_4Sb_2O_7$; *v.* ANTIMONY, ACIDS OF (*v.* also arts. ACIDS and HYDROXIDES).

Antimony, iodide of. SbI_3. Only one iodide of Sb is known with certainty; van der Espt (*Ar. Ph.* [2] 117, 115) asserts that SbI_5 is produced by heating 1 part Sb with 5 parts I, or by leading SbH_3 into I in alcohol; but as SbI_3 is known to be produced by such processes the existence of the pentiodide is extremely doubtful (comp. Pendleton, *C. N* 48, 97). Mol. w. 499·62. [167°] (Cooke, *P. Am. A.* [2] 5, 72). (401° at 760 mm.) (Cooke, *P. Am. A.* [2] 7, 251). V.D. 252 (Worcester, *P. Am. A.* [2] 10, 61). S.G. hexagonal $^{24°}$ 4·848, monoclinic $^{24°}$ 4·768 (Cooke, *l.c.*). H.F. solid Sb, gaseous I, $[Sb, I^3] = 45{,}400$ (Guntz, *C. R.* 101, 161).

Formation.—1. By the action of powdered Sb on I in CS_2.—2. By the action of SbH_3 on I.—3. By subliming together Sb_2S_3 with 3I in a globe (Schneider, *P.* 109, 609).

Preparation.—Powdered Sb is added little by little to I, with gentle heating, until no further action occurs; the SbI_3 is then separated by sublimation in H or CO_2.

Properties.—Red crystals, which melt on heating and volatilise in red vapours; soluble in boiling CS_2, and boiling benzene, but separates out on cooling; almost insoluble in $CHCl_3$; soluble in HIAq. Exists in three forms: (*a*) hexagonal ruby-red crystals, by crystallisation from CS_2, M.P. = 167°, *a*:*c* = 1:1·37; (*b*) trimetric greenish-yellow crystals, by subliming the hexagonal form at temperatures not above 114°; at 114° the change is sudden, the external form of the hexagonal crystals is preserved but each crystal is found to consist of a mass of trimetric crystals; heated above 114° the hexagonal form is reproduced; (*c*) monoclinic crystals (*a*:*b*:*c* = 1·6408:1: ·6682) obtained by exposing a solution of SbI_3 in CS_2 to direct sunlight; at 125° they are changed into the hexagonal form (Cooke, *P. Am. A.* [2] 5, 72).

Reactions.—1. *Water* decomposes SbI_3 with production of HIAq, which dissolves part of the SbI_3, and oxyiodide of Sb (*q. v.*).—2. *Aqueous alkalis and alkali carbonates* produce Sb_2O_3 and alkali iodide (Serullas, *J. Ph.* 14, 19).—3. Conc. *sulphuric acid or nitric acid* separates I.—4. *Alcohol or ether* partly dissolves SbI_3 and partly changes it to yellow oxyiodide (Macivor, *C. J.* [2] 14, 328).—5. *Chlorine* forms $SbCl_3$ and ICl (Macivor, *l.c.*).—6. *Antimony trisulphide* reacts with molten SbI_3 to form SbSI; this sulphoiodide is obtained as a lustrous brown-red powder by treating the fused mass with dilute HClAq; it is decomposed by H_2O and KOHAq; boiled with H_2O and ZnO the oxysulphide Sb_2OS_2 is formed (Schneider, *P.* 110, 147).

Combinations.—Dissolves in aqueous solutions of the *iodides of the alkali metals*, on evaporation double compounds are obtained. These compounds are soluble in HClAq, $H.C_2H_3O_2Aq$, and $H_2.C_4H_4O_6Aq$; they are decomposed by H_2O, yielding Sb oxyiodide; CS_2 dissolves out SbI_3. The following salts are described by Schaeffer (*P.* 109, 611): $2SbI_3.3KI.3H_2O$; $2SbI_3.3NaI.12H_2O$; $4SbI_3.3NH_4I.9H_2O$; $SbI_3.BaI_2.9H_2O$. Nicklès (*C. R.* 51, 1097) describes two series of compounds $MI.SbI_3.2H_2O$, and $MI.SbI_3.H_2O$ where M = K, Na, or NH_4, obtained usually by the action of I on Sb in presence of saturated MIAq; these salts are isomorphous with corresponding double salts of Bi.

Antimony, livers of. This name is applied to the impure double sulphides obtained by heating Sb_2S_3 with various metallic sulphides, more especially with the alkali and alkaline earth sulphides. These bodies are obtained either by fusing Sb_2S_3 with K_2S, &c., with K_2SO_2 &c. and C, or by dissolving Sb_2S_3 in K_2SAq, &c. The behaviour of aqueous solutions varies according to the relative quantities of Sb_2S_3 and alkali sulphide employed; if not more than 2 parts Sb_2S_3 are used to 1 part alkali sulphide, the product is wholly soluble in water; if more Sb_2S_3 is used the product is partly, or wholly, insoluble (because of production of antimonate and Sb_4O_6 *v.* ANTIMONIOUS SULPHIDE, *Reactions*, No. 15). Solutions of these bodies dissolve Sb_2S_3 on boiling; the Sb_2S_3 pps. again on cooling; they readily absorb O from the air, forming antimonate and thioantimonate (*v.* ANTIMONIOUS SULPHIDE, *Reactions*, No. 15). Addition of alkali bicarbonates pps. thioantimonite.

Antimony, oxides of. Three oxides are known: Sb_4O_6, Sb_2O_4, and Sb_2O_5; only the first of these has been gasified; the molecular weights of the others are not known. The pentoxide acts as an anhydride; the two others are feebly salt-forming whether they react with strong acids or strong alkalis (*v.* ANTIMONY, ACIDS OF). Marchand (*J. pr.* 34, 381) described an oxide, Sb_3O_2, said to be obtained by the electrolysis of a solution of cream of tartar; but Böttger (*J. pr.* 68, 372) failed to obtain anything except antimonic acid by repeating the experiments.

I. ANTIMONIOUS OXIDE Sb_4O_6 (*Antimonious acid*). Mol. w. 575·76. S.G. trimetric 5·5 to 5·6, regular octahedra 5·1 to 5·2 (Terreil, *C. R.* 58, 1209). V.D. 286·5 (at abt. 1550°; Meyer, *B.* 12, 1284). S.H. ·0927 (18° to 100°; Neumann, *P.* 126, 123). C.E. (40° cub., *Senarmontite*) ·00005889 (Fizeau, *A. Ch.* [4] 8, 335).

Occurrence.—Native; as *Antimony bloom* in trimetric prisms, as *Senarmontite* in octahedra.

Formation.—1. By heating Sb in a loosely covered crucible, and then raising the temperature, when Sb_4O_6 mixed with a little Sb_2O_4 sublimes on to the crucible cover.—2. By treating Sb with dilute HNO_3Aq and washing thoroughly with water and then with very dilute Na_2CO_3Aq (Rose, *P.* 53, 161).—3. By fusing Sb with KNO_3 and $KHSO_4$ and boiling fused mass in water (Preuss, *A.* 31, 197).—4. By washing the white pp. obtained by adding H_2O to $SbCl_3$ with dilute KOHAq and then with H_2O.—5. By adding excess of NH_3Aq to hot $KSb.C_4H_4O_7Aq$, heating pp. for a short time in contact with the liquid, collecting, and washing.

Preparation.—1. 3 parts finely powdered Sb are heated with 7 parts conc. H_2SO_4; the crude Sb sulphate is treated repeatedly with hot water, and then with very dilute Na_2CO_3Aq, and the oxide is collected and dried.—2. 1 part powdered Sb is heated, so long as an action occurs, with 4 parts HNO_3Aq, S.G. 1·2, and 8 parts H_2O; the nitrate of Sb is treated as the sulphate in 1.

Properties.—A white, more or less crystalline, powder (regular octahedra); very slightly soluble in water, fairly soluble in glycerine (Köhler, *D. P. J.* 258, 520); becomes yellow when heated, but white again on cooling; melts at a dark red heat, and crystallises on cooling. Volatilises rapidly about 1550° (Meyer, *B.* 12, 1284). Insoluble in HNO_3Aq and H_2SO_4Aq; dissolves easily in HClAq and $H_2.C_4H_4O_6Aq$; also in KOHAq and NaOHAq, from these solutions Sb_4O_6 is ppd. on cooling (Mitscherlich, *A. Ch.* [2] 33, 394), but according to Terreil the pp. is an antimonite (*A. Ch.* [4] 7, 380). Sb_4O_6 is formed in trimetric prisms (*a*:*b*:*c* = ·394:1:1·414) by burning Sb or Sb_2S_3 in air, by heating oxychloride (obtained by adding H_2O to $SbCl_3$) with H_2O to 150° (Debray, *C. R.* 58, 1209), or by rapidly subliming the octahedral crystals (Terreil, *C. R.* 62, 302); Sb_4O_6 is formed in regular octahedra by subliming at a dark red heat. Both forms are obtained by saturating hot Na_2CO_3Aq with Sb_2O_3 or $SbCl_3$ and allowing to cool (Mitscherlich, *P.* 15, 453); or by passing a slow stream of dry air through a porcelain tube containing Sb, the tube being heated at first only where the Sb is, but after a few hours also at the point where the prisms might condense, after about 12 hours prismatic crystals are found near the Sb, prisms mixed with octahedra further on, and octahedra only near the end of the tube (Terreil, *l.c.*). Sb_4O_6 is isodimorphous with As_4O_6 (*q. v.*). According to Guntz (*C. R.* 98, 303) the change of prismatic Sb_4O_6 to octahedral is attended with production of 1200 gram units of heat per 576 grms. Sb_4O_6 changed.

Reactions.—1. Heated in air or *oxygen*, Sb_2O_4 is formed.—2. Conc. hot *nitric acid* oxidises to Sb_2O_4 and Sb_2O_5; it dissolves in *cold fuming* HNO_3 and forms $Sb_4O_6.N_2O_5$ (Peligot, *C. R.* 23, 709).—3. Treated with *fuming sulphuric acid*, small lustrous crystals are obtained, which, after drying for six months in contact with burnt clay have the composition $Sb_4O_6.2SO_3$; by treating these crystals with H_2O the salt $Sb_4O_6.SO_3$ is obtained (Peligot, *l.c.*). Schultz-Sellac (*B.* 4, 13) describes the salt $Sb_2.3SO_4$ ($= Sb_4O_6.6SO_3$) as long lustrous needles obtained by evaporating solutions of Sb_4O_6 in fairly conc. H_2SO_4Aq; this salt is unchanged in dry air, but gives off SO_3 on heating, and is decomposed by water. $Sb_2(SO_4)_3$ is also formed by dissolving Sb_2S_3 in hot conc. H_2SO_4Aq (Hensgen, *R. T. C.* 4, 401) (*v.* SULPHATES).—4. Sb_4O_6 dissolves in solution of *potassium-hydrogen tartrate*, forming the salt $C_4H_4KSbO_7$, which is probably the K salt of the acid $Sb.C_4H_4O_6.OH$ (*v.* Clarke and Stallo, *B.* 13, 1787).—5. Sb_4O_6 acts as a reducing agent towards salts of silver, gold, &c. (*v.* ANTIMONY, DETECTION OF, *Antimonious compounds*).—6. Sb_4O_6 does not directly combine with *water*, but two hydrates have been prepared:—(*a*) $Sb_2O_3.2H_2O$, by adding $CuSO_4Aq$ to Sb_2S_3 dissolved in KOHAq until the filtered liquid gives a white pp. ($Sb_2O_3.2H_2O$) on addition of an acid (Fresenius; *v.* also Schaffner, *A.* 51, 182); (*b*) $Sb_2O_3.3H_2O$, a white powder which begins to lose water above 150°, obtained by the spontaneous decomposition of an aqueous solution of the acid $H.C_4H_4SbO_7$ obtained by decomposing $(C_4H_4SbO_7)_2Ba$ by the proper quantity of H_2SO_4Aq (Clarke a. Stallo, *B.* 13, 1793).—7. Dissolves in boiling *antimonious chloride* to form oxychlorides; $SbOCl.7SbCl_3$ is described by Schneider (*P.* 108, 407).

II. ANTIMONIC OXIDE Sb_2O_5 (*Antimonic acid*). Mol. w. unknown. S.G. 3·78 (Playfair a. Joule, *C. S. Mem.* 3, 83).

Preparation.—By dissolving powdered Sb in aqua regia, or conc. HNO_3Aq, evaporating to dryness, and heating [not above 275°] (Geuther, *J. pr.* [2] 4, 438; Dubrawa, *A.* 186, 110).

Properties.—Citron-yellow powder; insoluble in water, but reddens moist blue litmus paper; loses O at 300° (Geuther, *l.c.*) giving Sb_2O_4; soluble in conc. HClAq, slightly soluble in conc. KOHAq.

Reactions.—1. Heated with *antimony* or *antimony sulphide*, Sb_2O_3 is formed.—2. Heated in *chlorine*, $SbCl_3$ and Sb_2O_4 are produced.—3. Heated with *ammonium chloride*, is completely volatilised.—4. Reacts with *alkaline carbonates* on fusion, with evolution of CO_2 (*v.* further ANTIMONY, DETECTION OF, *Antimonic compounds*).—5. Hydrates are not produced by the direct action of water, but indirectly the three compounds, $Sb_2O_5.3H_2O$, $Sb_2O_5.2H_2O$, and $Sb_2O_5.H_2O$, have been obtained (*v.* ANTIMONY, ACIDS OF, ANTIMONATES). Forms many compounds with WO_3 and MoO_3 (*v.* Gibbs, *C. N.* 48, 155; *Am.* 7, 209 and 313).

III. ANTIMONOSO-ANTIMONIC OXIDE Sb_2O_4 (*Antimony tetroxide*). Mol. w. unknown. S.G. 4·074 (Playfair a. Joule, *C. S. Mem.* 3, 83); 6·5 (Boullay, *A. Ch.* [2] 43, 266). S.H. (23°-99°) ·09535 (Regnault, *A. Ch.* [3] 1, 129).

Occurrence.—Native, as *Antimony-ochre.*

Preparation.—1. By heating Sb_4O_6 in air.—2. By oxidising Sb, Sb_4O_6, or Sb_2S_3, by conc. HNO_3Aq, evaporating to dryness, and strongly heating.

Properties.—White powder, becoming yellow on heating; has not been melted or volatilised; insoluble in water, but reddens moist blue litmus paper; very slightly acted on by acids.

Reactions.—1. Heated with *solution of cream of tartar*, $Sb_2O_5xH_2O$ remains and solution contains $C_4H_4KSbO_7$.—2. Solution in HClAq dropped into *water*, is decomposed into Sb_4O_6 and Sb_2O_5.—3. Heated with *antimony* Sb_4O_6 is formed.—4. With *molten potash* forms $K_2O.Sb_2O_4$ (*v.* ANTIMONY, ACIDS OF; ANTIMONOSO-ANTIMONATES); solution of this in water slowly reduces $AgNO_3Aq$ and $AuCl_3Aq$. Sb_2O_4 reacts as a compound of Sb_2O_3 and Sb_2O_5 ($= Sb_4O_8$); it is sometimes regarded as antimonyl antimonate $(SbO)SbO_3$, derived from $HSbO_3$.

Antimony, oxybromides of. Two oxybromides are obtained by the action of H_2O on $SbBr_3$, viz. $Sb_4O_5Br_2$ and $10Sb_4O_5Br_2.SbBr_3$; SbOBr is probably formed by the action of sunlight on $SbBr_3$ in CS_2 (*v.* ANTIMONY, BROMIDE OF).

Antimony, oxychlorides of. At least six compounds are known; SbOCl, $SbOCl.7SbCl_3$, $Sb_4O_5Cl_2$, and $10Sb_4O_5Cl_2.SbCl_3$, obtained from $SbCl_3$; SbO_2Cl, and $SbOCl_3$, from $SbCl_5$.

When $SbCl_3$ is added to a little water, SbOCl is obtained (sometimes mixed with $SbCl_3$). This oxychloride seems to exist either as a white amorphous powder, or as monoclinic crystals isomorphous with SbOI (Cooke, *P. Am. A.* [2] 5, 72); the crystals are best obtained by using 10 pts. $SbCl_3$ and 17 pts. H_2O, allowing to stand for a day or two, pressing, and washing with ether (Sabanajew, *Bl.* [2] 16, 79); the amorphous powder is best prepared by adding 3 pts. H_2O to 1 pt. $SbCl_3$, filtering at once, drying over H_2SO_4, and washing with ether. Crystalline SbOCl is also obtained by heating $SbCl_3$ with C_2H_6O (in ratio $SbCl_3$:C_2H_6O) in a closed tube to 160° (Schäffer, *A.* 152, 314). By the action of much water on $SbCl_3$ (5 to 50 parts to 1 part $SbCl_3$ according to Sabanajew, *l.c.*) the oxychloride $Sb_4O_5Cl_2$ is obtained as an amorphous powder, which becomes crystalline on standing. To prepare the crystalline forms it is best to use 30 parts of cold water, or 3 parts of water at 60° to 70° (in the latter case allowing the pp. to remain a few hours before collecting); there are some differences in the forms of the two sets of crystals (Sabanajew, *l.c.*). Crystals (trimetric Schäffer, *A.* 152, 314; monoclinic, Cooke, *P. Am A.* [2] 5, 72) of $Sb_4O_5Cl_2$ are also obtained by heating $SbCl_3$ with C_2H_6O (in ratio $SbCl_3$:$3C_2H_6O$) to 140°-150° (Schäffer, *l.c.*). The compound $Sb_4O_5Cl_2$ is also produced by the action of alcohol on SbOCl (Schneider, *P.* 108, 407); and also by heating dry SbOCl ($5SbOCl = Sb_4O_5Cl_2 + SbCl_3$; Sabanajew, *l.c.*).

The product of the action of much H_2O on $SbCl_3$ is known as *powder of Algaroth*; the composition varies according to temperature, quantity of water, and quantity of HCl in the solution of $SbCl_3$ used (comp. Duflos, *S.* 67, 268; Johnston, *J. pr.* 6, 55; Malaguti, *J. pr.* 6, 253; Peligot, *A.* 64, 280).

According to Williams (*C. N.* 24, 224) the action of hot water on $SbCl_3$ produces $10Sb_4Cl_2O_5.SbCl_3$; Williams also describes two oxychlorides obtained by heating Sb_2O_5 with $SbCl_3$ (Sb_2O_5:$3SbCl_3$) to 140° in a closed tube; Sb_3OCl_{13} M.P. = 85°, and $Sb_3O_4Cl_7$ M.P. = 97·5°.

Cooke (*P. Am. A.* [2] 5, 72) describes another oxychloride $Sb_8O_{11}Cl_2$; and Schneider (*P.* 108, 407) two others, $SbOCl.7SbCl_3$ and $2SbOCl.Sb_2O_3$.

According to Thomsen (*Th.* 2, 240) the heat of formation of $Sb_4O_5Cl_2$ from $SbCl_3$ and Aq is 8910 gram-units (*v.* also Guntz, *C. R.* 98, 512). By dropping the calculated quantity of very cold water on to $SbCl_5$, Dubrawa (*A.* 184, 118) obtained $SbOCl_3$ ($SbCl_5 + H_2O = SbOCl_3 + 2HCl$); this oxychloride is a yellowish, somewhat crystalline, mass, soluble in alcohol; it deliquesces to a yellow liquid, from which needle-shaped crystals separate in dry air. When heated it melts and decomposes (probably to $SbOCl + Cl_2$). It is decomposed by Na_2CO_3Aq ($2SbOCl_3 + 3Na_2CO_3Aq = 6NaClAq + 2O + 3CO_2 + Sb_2O_3$).

Antimony, oxyfluoride of. $3SbOF.SbF_3$ obtained by deliquescence of SbF_3 (*v.* ANTIMONY, FLUORIDES OF).

Antimony, oxyiodides of. $Sb_4O_5I_2$ and SbOI. $Sb_4O_5I_2$ is obtained as light yellow crystals by evaporating a solution of $SbCl_3$ in KIAq, adding H_2O and evaporating again. The composition of the oxyiodide obtained by the action of H_2O on SbI_3 varies according to the conditions of its preparation; by pouring SbI_3 in HIAq into hot H_2O, $Sb_4O_5I_2$ is obtained (*v.* Macivor, *C. J.* [2] 14, 328). By the action of air and sunlight on SbI_3 in CS_2 both oxyiodides are formed, production of SbOI proceeding rapidly (Cooke, *P. Am. A.* [2] 5, 72). When SbOI is heated in a current of an inert gas to 150°, SbI_3 begins to sublime, and at 200° is given off rapidly; no further change occurs till 350° is reached, when SbI_3 again sublimes and crystals of Sb_2O_3 remain (Cooke, *P. Am. A.* [2] 5, 72). By the action of HClAq, HNO_3Aq, or H_2SO_4Aq, on SbOI, I is separated.

Antimony, oxysulphides of. Various oxysulphides of Sb, or more probably mixtures of Sb_2S_3 and Sb_2O_3, were formerly used in pharmacy. The compound $Sb_2O_3.2Sb_2S_3$ occurs native as *antimony blende* (*v.* H. Rose, *P.* 3, 452). The oxysulphide Sb_2OS_2 is obtained as a red-brown powder by boiling SbSI (*v.* ANTIMONY, IOXIDE OF) with ZnO and H_2O (Schneider, *P.* 110, 147); also by the action of $Na_2S_2O_3Aq$ on $SbCl_3$ in HClAq (Böttger, *C. C.* 1857. 333). A compound of Sb_2S_3 and Sb_2O_3 is much used as a brilliant crimson-red pigment; it is probably $Sb_2O_3.2Sb_2S_3$ (= $3Sb_2OS_2$), (*v.* Böttger, *l.c.*; Wagner, *J.* 1858. 235; Kopp, *C. C.* 1859. 945).

Antimony, phosphides of, *v.* ANTIMONY, *Combinations*, No. 8.

Antimony, selenides of, *v.* ANTIMONY, *Combinations*, No. 6.

Antimony, seleno-acid of, *v.* SELENO-ANTIMONATES, p. 286.

Antimony, sulphides of. Two sulphides are known, Sb_2S_3 and Sb_2S_5; neither has been gasified, and therefore mol. w. of neither is known. Unger (*Ar. Ph.* [2] 147, 193) supposed he had obtained a disulphide, Sb_2S_2, by the action of NaOHAq on Sb_2S_3; but the existence of this Sb_2S_2 is very doubtful. Sb_2S_3 is a feebly marked salt-forming sulphide, *e.g.* it dissolves in NaOHAq to form $Na_2Sb_2S_4$ (*v.* ANTIMONY, THIO-ACIDS OF). Sb_2S_5 is a distinctly salt-forming sulphide; the thio-antimonates (*q. v.*) are well-marked salts. The trisulphide, Sb_2S_3, occurs native; the pentasulphide does not.

I. ANTIMONIOUS SULPHIDE (*Antimony trisulphide, Mineral Kermes, &c.*) Sb_2S_3 [low red heat]. S.G. (*stibnite*) 4·51–4·75; (amorphous) 4·15; (fused, by direct union of Sb and S) 4·892 (Ditte, *C. R.* 102, 212). S.H. (23°–99°) ·08433 (Regnault, *A. Ch.* [3] 1, 129; *v.* also Neumann, *P.* 23, 1). Two forms are known; crystallised (trimetric; $a{:}b{:}c = {\cdot}985{:}1{:}1{\cdot}0117$) and amorphous.

Occurrence.—Native as *Stibnite* or *Antimony glance*, crystallised in trimetric prisms, usually containing P, As, Fe, and Cu.

Preparation.—(*a*) Crystallised: by gradually heating to redness, in a covered crucible, a mixture of 13 parts of finely powdered Sb well mixed with 5 parts pure S; then fusing for some time under a layer of NaCl; cooling, powdering, mixing with a little S, and again fusing under NaCl. (*b*) Amorphous: by boiling 4 parts KOHAq, S.G. 1·25, and 12 parts H_2O, with one part crude Sb_2S_3, out of contact with air for some time, adding 50 parts boiling H_2O, filtering quickly, and decomposing the solution by dilute H_2SO_4Aq; the pp. is collected, boiled with very dilute H_2SO_4Aq, washed with cold water, digested with aqueous tartaric acid (to remove any Sb_2O_3), again washed with cold water, pressed, and dried at a low temperature. Cooke (*P. Am. A.* [2] 5, 1) dissolves Sb in large excess of HNO_3Aq (S.G. 1·35), keeping the temperature as low as possible, neutralises with NaOHAq, dissolves in large excess of $H_2.C_4H_4O_6Aq$, pps. by H_2S in an atmosphere of CO_2, collects and washes pp. and dries below 210°. The amorphous sulphide is also produced by melting crystalline Sb_2S_3 in a glass tube, and after a time throwing it into a large quantity of cold water (Fuchs, *P.* 31, 578). An impure Sb_2S_3, containing Sb_2O_3, known as *Kermes*, is prepared for commercial purposes by heating crude antimony sulphide with aqueous alkalis or alkaline carbonates.

Properties.—(*a*) Crystalline: grey-black trimetric prisms; melts easily. (*b*) Amorphous: prepared by ppn., is a reddish-brown, loose, powder which marks paper with a brownish streak; prepared by melting and suddenly cooling the crystalline Sb_2S_3, it is a hard greyish mass; melted and cooled slowly it yields the crystalline form; heated to 210°–220° it becomes grey (Cooke, *P. Am. A.* [2] 5, 1). Both forms of Sb_2S_3 are insoluble in water, and in NH_3Aq, dissolve in KOHAq, in HClAq, and very slowly in tartaric acid. They may be distilled unchanged in a stream of N.

Reactions.—The products of the reactions of crystalline and amorphous Sb_2S_3 are, in almost every case, the same; the actions usually proceed more rapidly with the amorphous than with the crystalline form. 1. Boiled with *water*, is partially decomposed to Sb_4O_6 and H_2S (De Clermont a. Frommel, *C. R.* 87, 330; Lang, *B.* 18, 2714).—2. Heated in *hydrogen*, Sb is formed.—

3. *Calcined in air*, Sb_4O_6, or Sb_2O_4, and SO_2 are produced.—4. Heated in *chlorine*, $SbCl_3$ and S_2Cl_2 result.—5. Aqueous *hydrochloric acid* forms $SbCl_3$ and H_2S; after a time the action stops, but if the H_2S is removed the whole of the Sb_2S_3 is decomposed (*v.* Lang, *B.* 18, 2714; also Berthelot, *C. R.* 102, 22).—6. *Conc. nitric acid* oxidises to nitrate and sulphate of Sb mixed with S.—7. *Aqua regia* forms $SbCl_3$, H_2SO_4, and S.—8. Dilute solutions of *sulphuric acid* have no action on crystalline Sb_2S_3, but slowly evolve H_2S from amorphous Sb_2S_3; conc. H_2SO_4Aq evolves SO_2, separates S, and forms $Sb_2(SO_4)_3$ (Hensgen, *R. T. C.* 4, 401).—9. Fused with at least 17 parts *nitre*, $KSbO_3$ is formed, with Sb sulphate; with less than 17 parts nitre, Sb_2O_3 is sometimes formed in addition to the other products, or a part of the Sb_2S_3 remains unoxidised and combines with K_2S formed to produce a thio- salt.—10. Melted with excess of *lead oxide*, Sb_2O_3, SO_2, (and Pb), are formed.—11. Melted with *potassium cyanide*, Sb is produced, along with KCNS and a compound of Sb_2S_3 and K_2S.—12. *Iron, zinc,* and many other *metals* reduce Sb_2S_3, when heated with it, forming Sb and a metallic sulphide; metals whose sulphides are basic (*e.g.* K) generally combine with part of the Sb_2S_3 to form thio- salts.—13. Many *easily reduced metallic oxides* when heated with Sb_2S_3 form Sb_2O_4 and SO_2.—14. Many *metallic sulphides* combine when heated with Sb_2S_3 with production of double compounds; several of these double compounds occur native, *e.g.* $Sb_2S_3.PbS$; $Sb_2S_3.Cu_2S$; $Sb_2S_3.3Ag_2S$; &c.—15. *Alkali sulphides* combine with Sb_2S_3 either when heated in the solid state or in solution; the compounds produced are generally known as *livers of antimony*, *q. v.* (*v.* also next reaction); aqueous solutions of these compounds absorb O forming Sb_4O_6, antimonates, and thio-antimonates.—16. *Caustic alkalis* react with Sb_2S_3, when fused together, or when in aqueous solutions, to produce antimonite and thio-antimonite: thus, $4Sb_2S_3 + 4K_2O = 6KSbS_2 + 2KSbO_2$; or $4Sb_2S_3 + 8KOHAq = 3(Sb_2S_3.K_2SAq)$ $[= 6KSbS_2Aq]$ $+ Sb_2O_3.K_2OAq$ $[= 2KSbO_2Aq] + 4H_2O$. Addition of HClAq to this solution pps. Sb_2S_3;
$(6KSbS_2Aq + 2KSbO_2Aq + 8HClAq = 4Sb_2S_3 + 8KClAq + 4H_2O)$. If, however, much Sb_2S_3, relatively to the amount of KOH, is used, formation of $KSbS_2Aq$ proceeds, but the $KSbO_2$ being much less soluble pps. along with some oxysulphide and Sb_4O_6 which has not combined with KOH (*crocus of antimony*). The solution of $KSbS_2$ is acted on by air, giving finally antimonate and thio-antimonate $(6KSbS_2Aq + 6O = 4KSbS_3Aq + 2KSbO_3Aq)$.—17. *Solutions of carbonated alkalis*, K_2CO_3 and Na_2CO_3Aq, dissolve Sb_2S_3 only on heating; the solutions behave similarly to those obtained by KOHAq and NaOHAq; on boiling in air a pp. of $KSbO_3$ $(Sb_2O_5.K_2O)$ combined with Sb_2S_3 is obtained (*Kermes*), and $KSbS_3$ remains in solution. When 1 pt. Sb_2S_3 is fused at a strong red heat with 3 pts. Na_2CO_3, and H_2O is added, a solution containing antimonate and thio-antimonate is obtained, and Sb is ppd. (probably, $10NaSbO_2Aq + 2H_2O = 6NaSbO_3Aq + 4NaOHAq + 4Sb$). The action of alkalis on Sb_2S_3 has been chiefly investigated by Liebig (*A.* 7, 1).

Combinations.—With metallic sulphides to form thio-antimonites (*v. supra*), *q.v.* under ANTIMONY, THIO-ACIDS OF.

Antimonious sulphide; hydrated. The orange-red pp. obtained by passing H_2S into a solution of $SbCl_3$ or $C_4H_4KSbO_7$ containing little acid is amorphous hydrated Sb_2S_3, which is fully dehydrated only at 200° (Fresenius; according to Wittstein the pp. contains no chemically combined H_2O, *Fr.* 1870. 262). It behaves towards acids, alkalis, &c. in the same way as amorphous Sb_2S_3. When this pp. is treated with *peroxide of hydrogen*, in presence of NH_3Aq, a portion of it is oxidised to antimonic acid, some of which separates out and some remains in solution as $NH_4.SbO_3$ (Raschig, *B.* 18, 2743).

II. ANTIMONIC SULPHIDE Sb_2S_5 (*Antimony pentasulphide or persulphide, Golden sulphuret of antimony*, &c.). Mol. w. unknown. Not found native. Sb_2S_3 does not directly combine with S; but by heating Sb_2S_3, S, and Na_2CO_3 together, Na_3SbS_4 is formed, from which Sb_2S_5 is obtained by the action of acids.

Formation.—1. By the action of H_2S on $SbCl_5$ in $H_2.C_4H_4O_6Aq$, or on $Sb_2O_5.xH_2O$ suspended in water.—2. By decomposing solutions of thio-antimonates by dilute acid.

Preparation.—10 parts crystallised $Na_3SbS_4.9H_2O$ (*q. v.* under ANTIMONY, THIO-ACIDS OF) are dissolved in 60 parts H_2O; the solution is poured (with constant stirring) into a cold solution of 3·3 parts pure H_2SO_4 in 100 parts H_2O; the pp. is washed by decantation, then on a filter, with cold water, as quickly as possible; to remove all traces of acid, the pp. is now digested with a cold solution of 1 part $NaHCO_3$ in 20 parts H_2O for a few days; it is again washed then pressed, and dried in a dark place at a low temperature.

Properties.—A dark-orange powder; insoluble in water; completely soluble in aqueous alkalis; in absence of air, soluble in NH_3Aq, and in aqueous alkali sulphides; soluble in Na_2CO_3 or K_2CO_3Aq, not in $(NH_4)_2CO_3Aq$.

Reactions.—1. *Heated out of contact with air*, Sb_2S_3 and S are formed.—2. Decomposed by boiling with *hydrochloric acid*, giving $SbCl_3$ and H_2S.—3. *Caustic alkalis* dissolve Sb_2S_5, forming antimonate and thio-antimonate.—4. *Carbon disulphide* dissolves out a little S (about 5 p.c., Rammelsberg, *P.* 52, 193). That this is due to a decomposition of Sb_2S_5, and not to the action of CS_2 on admixed S (it has been supposed that the action of CS_2 proves the non-existence of Sb_2S_5), is shown by the fact that much less than S_2 is withdrawn from each Sb_2S_5 by CS_2, and also by the reactions of the Sb_2S_5, especially the solubility in NH_3Aq in which Sb_2S_3 is insoluble, and the insolubility in $(NH_4)_2CO_3Aq$ which dissolves Sb_2S_3.

Combinations.—With alkali sulphides to form thio-antimonates, *q.v.* under ANTIMONY, THIO-ACIDS OF.

Antimony, sulpho-acids of, *v.* ANTIMONY, THIO-ACIDS OF.

Antimony, sulpho- (or thio)- chlorides of. $SbSCl.7SbCl_3$, and $2SbSCl.Sb_2S_3$, obtained by action of Sb_2S_3 on $SbCl_3$; and $SbSCl_3$ obtained by the action of H_2S on $SbCl_5$ (*v.* ANTIMONY, CHLORIDES OF).

Antimony, sulpho- (or thio)- iodides of. $SbSI$; by action of Sb_2S_3 on SbI_3, or of I on Sb_2S_3 (*v.* Antimony, iodide of).

Antimony, tellurides of, *v.* Antimony, *Combinations*, No. 7.

Antimony, thio-acids of. No thio-acids of Sb are known, but a few thio-antimonites, $MSbS_2$ and one M_3SbS_3, and a considerable number of well-marked thio-antimonates, M_3SbS_4, have been prepared. The thio-antimonites may be regarded as derived from the hypothetical acid $HSbS_2$ ($=SbS.SH$); they correspond in composition with the antimonites $MSbO_2$ and with the meta-thio-arsenites $MAsS_2$. The thio-antimonates may be regarded as derived from the hypothetical acid H_3SbS_4 ($=SbS(SH)_3$); nc corresponding antimonates are known ($MSbO_3$ and $M_4Sb_2O_7$ represent the antimonates); the thio-arsenites are represented by three series, one of which (the ortho-series) corresponds with the thio-antimonates.

Thio-antimonites. A very few of these salts have been prepared. Addition of absolute alcohol to a solution of Sb_2S_3 in NaOHAq pps. amorphous $NaSbS_2$, soluble in water. By heating to 30° equivalents of Sb_2S_3 and NaOH (in conc. solution) copper-coloured $2NaSbS_2.H_2O$ is formed (Unger, *J.* 1871. 325). The silver salt Ag_3SbS_3 is said to be obtained as a grey mass, reddish when powdered, by heating Ag_3SbS_4 out of contact with air (Rammelsberg, *P.* 52, 193). Several minerals may be regarded as thio-antimonites, *e.g.* $PbS.Sb_2S_3$; $Ag_2S.Sb_2S_3$; $Cu_2S.Sb_2S_3$; $FeS.Sb_2S_3$ &c.

Thio-antimonates M_3SbS_4. Investigated chiefly by Rammelsberg (*P.* 52, 193). Some of these salts are obtained by the action of alkali sulphides on Sb_2S_5; but they are better obtained by acting on Sb_2S_3 with aqueous solutions of alkali sulphides in presence of sulphur, or with aqueous solutions of alkali polysulphides. They are also obtained by fusing Sb_2S_3 with alkali sulphides (or with sulphates and carbon) and sulphur. The decomposition, in air, of alkaline livers of antimony also often yields thio-antimonates (*v.* Antimonious sulphide, *Reactions*, No. 15 and 16). The thio-antimonates of the alkali metals are soluble in water, many of the others are insoluble and are obtained from the alkali salts by ordinary double decompositions, the metallic salt solution being added in quantity less than sufficient to decompose the whole of the alkali thio-antimonate. Solutions of thio-antimonates are easily decomposed by acids, even by the CO_2 of the air, with ppn. of Sb_2S_5, and, when exposed to air, of alkali thio-sulphate. The alkali thio-antimonates are not decomposed by heating out of contact with air; the salts of the heavy metals lose S, and give thio-antimonites. The more important thio-antimonates are those of potassium and sodium.

Potassium thio-antimonate. $2K_3SbS_4.9H_2O$; slightly yellow deliquescent crystals; prepared by boiling, for several hours, 1 part S, 6 parts K_2CO_3, 3 parts CaO, and 20 parts H_2O, with 11 parts Sb_2S_3, filtering, and cooling out of contact with air. A salt $K_3SbS_4.KSbO_3.5H_2O$ is obtained, in long white needles, by adding cold conc. KOHAq to Sb_2S_5, filtering from $2KH(SbO_3)_2.5H_2O$ which separates out, and evaporating (*v.* Schiff, *A.* 114, 202).

Sodium thio-antimonate $Na_3SbS_4.9H_2O$ (known as *Schlippe's salt*). Prepared by fusing together 16 parts dry Na_2SO_4, 13 parts Sb_2S_3, and 4–5 parts wood charcoal, dissolving in water, boiling with 2½ parts sulphur, filtering and evaporating; the crystals are washed with very dilute NaOHAq and then with water, and dried quickly at a low temperature. The salt may also be prepared by boiling Na_2CO_3Aq with CaO, Sb_2S_3, and S. Sodium thioantimonate forms large yellowish monometric tetrahedra; it dissolves in 2·9 parts H_2O at 15°, the solution has an alkaline reaction. The crystals are best kept in contact with their mother liquor to which a little NaOHAq is added; they decompose in air, giving Sb_2S_3, Sb_2S_5, Na_2S, Na_2CO_3, and $Na_2S_2O_3$. When the mother liquor from Schlippe's salt is evaporated, crystals of a double salt $Na_3SbS_4.Na_2S_2O_3.20H_2O$ are obtained. Solution of tartar emetic is decomposed by Na_3SbS_4Aq thus; $6C_4H_4KSbO_7Aq + 2Na_3SbS_4Aq =$

$$6C_4H_4KNaO_6 + Sb_4O_6 + Sb_2S_3 + Sb_2S_5.$$

The other thio-antimonates are generally obtained from the sodium salt: the best-marked are $Ba_3(SbS_4)_2.6H_2O$; $Cu_3(SbS_4)_2$; $Pb_3(SbS_4)_2$; $Hg_3(SbS_4)_2$; Ag_3SbS_4; a few others are known (*e.g.* of Cd, Co, Mn, Ni, V, Zn) but they are very easily decomposed, and not many have been obtained in definite forms. M. M. P. M.

ANTIMONY, Compounds with organic radicles.

Tri-methyl-stibine $SbMe_3$. Mol. w. 167. (81°). S.G. $\frac{15}{}$: 1·523.

Preparation.—An alloy of antimony (4 pts.) and sodium (1 pt.) is mixed with sand and MeI and distilled. MeI and $SbMe_3$ pass over but unite in the receiver to form $SbMe_4I$, which when distilled with an alloy of antimony and potassium in a current of CO_2 gives $SbMe_3$ (Landolt).

Properties.—Liquid, smelling of onions, sl. sol. water; may take fire in air. Takes fire in chlorine. Reduces salts of silver and mercury.

Salts.—Unites directly with non-metals.—$SbMe_3Cl_2$: hexagonal crystals, sl. soluble in water. Formed also from $SbCl_3$ and $HgMe_2$.—$SbMe_3Cl_2SbMe_3O$: octahedra, sol. water.—$SbMe_3Br_2$.—$SbMe_3Br_2,SbMe_3O$: octahedra, sol. water.—$SbMe_3I_2$: formed by heating Sb with MeI at 140°.—$SbMe_3I_2,SbMe_3O$: octahedra.—$SbMe_3S$: scales.—$SbMe_3(NO_3)_2$.—$SbMe_3SO_4$.

Tetra-methyl-stibonium salts. $SbMe_4I$. S. 80 at 23°. From $SbMe_3$ and MeI: six-sided plates. When distilled the vapour ($SbMe_3$ + MeI) takes fire in air.—$SbMe_4.OH$: from moist Ag_2O and the above. Deliquescent alkaline crystals: absorbs CO_2 from air, and expels NH_3 from its salts. Pps. baryta from BaI_2, also the hydrates of Pb, Ca, Cu, Hg, Ag, and Zn; only the last pp. is soluble in excess.—$SbMe_4Cl$: very soluble hexagonal plates; v. sl. sol. ether.—$(SbMe_4Cl)_2PtCl_4$: difficultly soluble orange powder; sl. sol. water, insol. alcohol and ether.—$SbMe_4Br$.—$(SbMe_4)_2S$:

soluble green powder; oxidises rapidly. — $SbMe_4NO_3$ [150°]: crystals, v. sol. water, not decomposed by boiling concentrated H_2SO_4.— $SbMe_4SO_4H$: soluble plates.—$(SbMe_4)_2SO_4$ 5aq.

Di-methyl-stibine sulphides $(SbMe_2)_2S_3$ [c. 100°] and $(SbMe_2)_2S$ are formed by passing H_2S into an ethereal solution of $SbMe_3$ that has been oxidised by exposure to air.

Antimony penta-methide $SbMe_5$. (c. 98°). Formed together with antimony tetra-methide, $(SbMe_4)_2$ (c. 90°), by distilling trimethyl stibine iodide with $ZnMe_2$. Both are oils which do not fume in air.

Methyl-tri-ethyl-stibonium salts $SbMeEt_3I$. S. 50 at 20°. From $SbEt_3$ and MeI. Glassy prisms, sol. alcohol, insol. ether; the solutions are lævorotatory. $HgCl_2$ gives a precipitate of $SbEt_3MeI\,1\frac{1}{2}HgI_2$.—$SbMeEt_3OH$; from moist Ag_2O and the iodide, or from the sulphate and baryta. Pps. metallic salts, the hydrates of zinc and aluminium dissolving in excess.— $SbMeEt_3Cl$: small needles. — $SbMeEt_3IHgI_2$.— $(SbMeEt_3)_2CO_3$: amorphous. — $(SbMeEt_3)_2SO_4$: [100°], deliquescent, shining, bitter crystals.— $(SbMeEt_3)_2C_2O_4$: glassy needles, m. sol. water.— $SbMeEt_3C_2O_4H$: needles, v. sol. water.—The *acetate*, *formate*, and *butyrate* are crystalline.

Tri-ethyl-stibine $SbEt_3$. Mol. w. 209. (159°). S.G. $\frac{16}{}$: 1·324. V.D. 7·44 (calc. 7·18).

Formation.—1. From $SbCl_3$ and $ZnEt_2$.— 2. From EtI and a mixture of sand with an alloy of Sb and potassium.—3. From $SbCl_3$ and $HgEt_2$.—4. By distilling $SbEt_3I_2$ with Zn.

Properties.—Oil, smelling of garlic, v. sol. alcohol and ether. Takes fire in air; hence it should be kept under water. Decomposes fuming hydrochloric acid with evolution of hydrogen: $SbEt_3 + 2HCl = SbEt_3Cl_2 + H_2$. When slowly oxidised it forms $SbEt_3O$ and $SbEt_4(SbO_2)_2$. Combines directly with S, Se, I, Br, and Cl. Dilute HNO_3 dissolves it, giving off NO and forming $SbEt_3(NO_3)_2$. In all these reactions tri-ethyl-stibine behaves like a metal. An alcoholic solution of $SbEt_3$ shaken with HgO liberates Hg while $SbEt_3O$ remains in the solution.

Tri-ethyl-stibine-oxide $SbEt_3O$.

Formation.—1. From $SbEt_3L_2$ and Ag_2O.— 2. From $SbEt_3SO_4$ and baryta.—3. By slow oxidation of an alcoholic or ethereal solution of $SbEt_3$; $SbEt_4(SbO_2)_2$ is formed at the same time, but this differs from $SbEt_3O$ in being insol. ether.—4. By shaking alcoholic $SbEt_3$ with HgO.

Properties.—A syrup, v. sol. water and alcohol, m. sol. ether; combines with acids and precipitates metals as hydrates from solutions of their salts. If its aqueous solution is free from $SbEt_3(SbO_2)_2$, no pp. is produced by H_2S; otherwise a pp. of $SbEt_4(SbS_2)_2$ is formed. Potassium converts it into $SbEt_3$.

Tri-ethyl-stibine salts.

Chloride.—$SbEt_3Cl_2$. S.G. $\frac{17}{}$: 1·540. Oil, soluble in alcohol. Ppd. by adding HCl to an aqueous solution of the iodide or sulphate. Conc. H_2SO_4 decomposes it, giving off HCl.

Oxy-chloride.—$SbEt_3Cl_2,SbEt_3O$. From the oxy-iodide and $HgCl_2$. Deliquescent solid.

Bromide. — $SbEt_3Br_2$. S.G. $\frac{17}{}$: 1·953. Solidifies at −10°. Insol. water, sol. alcohol and ether. Behaves like a metallic bromide.

Iodide.—$SbEt_3I_2$. [71°]. Formed by heating Sb with EtI at 140°; or by adding iodine to an alcoholic solution of $SbEt_3$ at −15°. Needles (from ether). Unlike the chloride, it is soluble in water. Potassium removes the iodine thus: $SbEt_3I_2 + K_2 = 2KI + SbEt_3$.

Oxy-iodide.—$SbEt_3I_2,SbEt_3O$. Formed by treating the iodide with NH_3; or by mixing the iodide with the oxide $SbEt_3O$.

Sulphide.—$SbEt_3S$. From the oxide and H_2S or from $SbEt_3$ and S. Soluble in water and alcohol. Its aqueous solutions pp. metals as sulphides from their salts.

Nitrate.—$SbEt_3(NO_3)_2$. [63°]. Formed by dissolving $SbEt_3$, or its oxide, in dilute HNO_3. Rhombohedra, soluble in water.

Oxy-nitrate.—$SbEt_3O, HNO_3$. From the oxy-iodide and $AgNO_3$.

Sulphate.—$SbEt_3SO_4$ [100°]. From the sulphide and $CuSO_4$. Small prisms, sol. water and alcohol.

Oxy-sulphate.—$(SbEt_3O)_2H_2SO_4$. From the oxy-iodide and Ag_2SO_4. Gummy mass.

Tetra-ethyl-stibonium salts.

Iodide.—$SbEt_4I, 1\frac{1}{2}$aq (and $\frac{3}{4}$aq). S. (anhydrous): 19 at 20°. From $SbEt_3$, water, and EtI at 100°. Hexagonal prisms, sol. alcohol and ether.—$SbEt_4I\,\frac{2}{3}HgI_2$.—$SbEt_4I\,\frac{3}{4}HgI_2$.

Hydrate.—$SbEt_4OH$. From moist Ag_2O and the above. Alkaline syrup. Pps. metallic hydrates from salts: stannic oxide and alumina dissolve in excess. Expels NH_3 from its salts.

Chloride.—$SbEt_4Cl$. Hygroscopic needles. Forms compounds with $HgCl_2$ and with $PtCl_4$.

Bromide.—$SbEt_4Br$Aq: needles.

Periodide.—$SbEt_4I_3$.

Nitrate.—$SbEt_4NO_3$: deliquescent needles.

Sulphate.—$(SbEt_4)_2SO_4$: deliquescent mass.

Oxalate.—$(SbEt_4)_2C_2O_4$.

Antimony-penta-ethide $SbEt_5$ (?). (c. 165°). From $SbEt_3I_2$ and $ZnEt_2$.

Tri-isoamyl-stibine $Sb(C_5H_{11})_3$. From an alloy of Sb with K by $C_5H_{11}I$. Fuming liquid, does not take fire in air.

Oxide.—$Sb(C_5H_{11})_3O$: insoluble resin, soluble in alcohol.

Salts. — $Sb(C_5H_{11})_3Cl_2$: oil, heavier than water, soluble in alcohol, ppd. by water.— $Sb(C_5H_{11})_3Br_2$: oil. — $Sb(C_5H_{11})_3I_2$: oil. — $Sb(C_5H_{11})_3(NO_3)_2$: [20°] slender crystals, insoluble in water, soluble in alcohol.—$Sb(C_5H_{11})_3SO_4$: oil.

Antimony di-isoamyl $Sb_2(C_5H_{11})_4$ (?). Formed by distilling $Sb(C_5H_{11})_3$. A heavy oil, soluble in alcohol. Does not fume in air, but explodes in oxygen. Its salts are amorphous.

Tri-phenyl-stibine $SbPh_3$. [48°] (above 360°). S.G. $\frac{12}{}$ 1·500. From $SbCl_3$ (1 pt.), chloro-benzene (1 pt.) and Na; benzene being used as diluent. Small quantities of $SbPh_2Cl_3$ and $SbPh_3Cl_2$ are also formed. The benzene deposits crystalline $SbPh_3$; this is warmed with alcohol containing HCl, which dissolves $SbPh_2Cl_3$, and the residual $SbPh_3$ is converted into $SbPh_3Cl_2$ by chlorine. The latter is reduced by alcoholic ammonia and hydrogen sulphide:

$$SbPh_3Cl_2 + H_2S = SbPh_3 + 2HCl + S.$$

Properties.—Colourless triclinic tables $a:b:c = \cdot697 : 1 : \cdot889$. $\alpha = 100° 38'$. $\beta = 103° 37'$. $\gamma = 75° 25'$; sl. sol. alcohol, v. e. sol. ether, benzene, glacial HOAc, CS_2, chloroform, and petroleum; insol. water and aqueous HCl. It does not decompose HCl; but it combines directly with halogens; it reduces cupric, to cuprous, chloride. With mercuric chloride it reacts as follows:

$$SbPh_3 + 3HgCl_2 = SbCl_3 + 3HgPhCl.$$

Fuming HNO_3 forms $SbPh_3(NO_3)_2$.

Salts.—$SbPh_3Cl_2$ [143°]: long thin needles; not affected by water; insol. light petroleum, sl. sol. ether and alcohol, v. sol. benzene and CS_2. —$SbPh_3Br_2$. [216°]. — $SbPh_3I_2$. [153°]; white tables. — $SbPh_3(OH)_2$. [212°]. From the bromide and alcoholic KOH. Amorphous powder, sol. glacial HOAc and reppd. unaltered by water. Insol. ether, v. e. sol. alcohol. Converted by HCl, HBr, or HI into haloid salt.—$SbPh_3(NO_3)_2$. [156°]. Insol. water, sol. alcohol.

Antimony di-phenyl chloride $SbPh_2Cl_3aq$. [180°]. Obtained as a by-product in preparing $SbPh_3$. Needles, insol. water, sol. hot dilute HCl, v. e. sol. alcohol. Alcoholic NH_3 converts it into $Ph_2SbO(OH)$, a white powder, insol. water, ammonia, alcohol, ether, or Na_2CO_3Aq, but sol. NaOHAq and glacial HOAc.

ANTIPYRINE *v. Oxy-di*-methyl-quinizine.

APHRODÆSCIN. A substance contained in the cotyledons of the horse-chestnut (*v.* Æscinic acid).

APIÏN. When common parsley (*Apium petroselinum*) is extracted with boiling water the filtrate gelatinises on cooling. The jelly is dried at 100° and extracted with alcohol, and the alcohol poured into water. The operation of dissolving in alcohol and ppg. with water is repeated several times, and the apiin finally crystallised from alcohol, with stirring. Apiin also occurs in parsley seed; if this is boiled with water, apiol distils over, while apiin separates out from the residue.

Properties.—Needles; sl. sol. cold water, v. sol. hot water, separating again as a jelly; v. sol. alcohol; insol. ether. Its solution in boiling water gives a blood-red colour with $FeSO_4$. Gives picric acid with HNO_3; and phloroglucin by potash fusion.

Apigenin $C_{15}H_{10}O_5$. Boiling dilute H_2SO_4 splits up apiin into apigenin and glucose:

$$C_{27}H_{32}O_{16} + H_2O = C_{15}H_{10}O_5 + 2C_6H_{12}O_6.$$

Crystallises in plates (from alcohol). It sublimes near 294°. Sl. sol. hot water, v. sol. alcohol, insol. ether. *Potash fusion* gives phloroglucin, protocatechuic acid, *p*-oxybenzoic acid, and oxalic acid.

References.—Rump, Buchner's *Repert. f. Pharm.* 6, 6; Braconnot, *A. Ch.* [3] 9, 250; v. Planta a. Wallace, *A.* 74, 262; Lindenborn, *B.* 9, 1123; v. Gerichten, *B.* 9, 1121; Whitney, *Ph.* [3] 10, 585.

APIOL $C_{12}H_{14}O_4$. [30°]. (c. 300°). Extracted by alcohol from parsley seeds (v. Gerichten, *B.* 9, 1477). Needles; insol. water. Alcoholic KOH converts it into two crystalline bodies. [54°] and [114°]. The essential oil obtained by distilling parsley seeds with water contains apiol but consists chiefly of a terpene, (160°-164°), S.G. ^{12} ·865, [α] −30·8°. It has a strong smell of parsley. A small quantity of a hydrochloride, [116°], can be got from it.

APO-. Compounds beginning with this prefix are described under the words to which it is prefixed.

APOCYNIN. The root of *Apocynum Cannabium* contains amorphous resinous apocynin, sol. alcohol and ether, v. sl. sol. water, and a glucoside, apocyneïn (Schmiedeberg, *Ph.* [3] 13, 942).

APOPHYLENIC ACID. The methylo-hydroxide of cinchomeronic acid; *v.* Pyridine di-carboxylic acid.

APPLES. The artificial essence of apples contains iso-amyl iso-valerate dissolved in rectified spirit (Hofmann, *A.* 81, 87).

APRICOTS. The artificial essence of apricots contains isoamyl butyrate and isoamyl alcohol.

AQUA REGIA *v.* Chlorhydric acid.

AQUA VITÆ. Alcohol.

ARABIC ACID (Arabin) $C_{12}H_{22}O_{11}$; $nC_6H_{10}O_5$ (Neubauer, *J. pr.* 62, 193; 71, 255); $C_{12}H_{22}O_{11}$ (Scheibler, *B.* 6, 612); $C_{89}H_{142}O_{74}$ (O'Sullivan, *C. J.* 45, 41).

Occurrence.—It is a constituent of probably all lævorotatory gums, and has been isolated from Levantine, Senari, East Indian, Senegal, and Turkey, gum; these gums contain also, as a rule, other acids different from, but closely allied to arabic acid (O'Sullivan). It exists in sugar-beet (Scheibler), and in the extract of yeast obtained by boiling water (Schützenberger, *Bl.* [2] 21, 204; *C. R.* 78, 493). The beet gum is probably related to arabic acid, but there is no evidence that the yeast-extract body belongs to the arabin group. Many gum-like constituents of seeds and roots are referred to as gums, but the great bulk of them obviously hold no relation to arabic acid. It is found in certain animals (Städeler, *A. Ph.* 111, 26).

Formation.—It is a product of the action of sulphuric acid on algæ-mucilage (Brown, *Ed. Ph. I.* 26, 409); on quince, linseed, and flea-wort mucilages, cellulose being at the same time produced (Kirchner a. Tollens, *A.* 175, 205); and on metagummic acid (Frémy, *C. R.* 50, 125). Cellulose is transformed into gum in plants (Mercadante, *G.* 5, 408). In none of these cases have we any information as to the character of the gum produced.

Preparation.—The lævorotatory gums are principally potassium, magnesium, and calcium salts of arabic or allied acids; they contain from 12 to 18 p.c. water, and yield 2·7 to 3·0 p.c. ash consisting almost wholly of carbonates of these metals. Any one of these gums is dissolved in the least possible quantity of water, the solution is allowed to stand, and, when clear, decanted from any insoluble matter. To the clear liquid twice or thrice as much HCl as is sufficient to convert the bases into chlorides is added, and the gum-acid or acids are precipitated by a moderate excess of alcohol. If the gum contains only arabic acid, the whole pp. can be purified as is described below when dealing with one of the fractions; but if, as is very frequently the case, other allied acids are also present, it is necessary to have recourse to fractional precipitation to isolate the arabic acid. It is found in the fractions least soluble in dilute alcohol, and may be obtained as follows:—The curdy pp., produced by excess of alcohol in presence of HCl, is well washed with spirit, and then pressed as free from it as possible. It is redissolved in warm water, care being taken to avoid heating for any length of time, because even the small quantity of HCl retained by the pp. has a tendency on heating even for a short time to decompose the arabic acid, as will be described below. The solution is cooled, and alcohol gradually added with continual stirring. In this way, the liquid can be made milky without the formation of a pp.; from this 'milk' the acid or acids can be precipitated in successive fractions by the addition of HCl in carefully graduated quantities. If 4 or 5 fractions are obtained, one or more of them is arabic acid. Each fraction is freed from ash by repeated precipitation from aqueous solution with alcohol in the least possible excess in presence of HCl, and from HCl by repeated precipitation from concentrated solution by the rapid addition of strong alcohol, whereby the production of a 'milk' is obviated. The fractions thus purified are treated with alcohol (S.G. ·81) to render them friable, rubbed down to a powder, filtered out, pressed, and dried over sulphuric acid. Thus prepared they are white, friable bodies, easily soluble in water. If in this state they are exposed for any length of time to a temperature of 100°, they are converted into the meta modifications (meta acids) which are insoluble in water and only swell up to jelly-like masses when treated with it. If, however, they are previously dried *in a vacuum* over sulphuric acid until the weight becomes constant, they can then be dried at 100° without becoming insoluble. The fraction or fractions which are found to have an optical activity, $[\alpha]_j = -26°$ to $-28°$, and which, when again divided, yield fractions each of which has the same activity, consist of arabic acid.

Properties.—Arabic acid, when slowly dried out of syrupy solutions, on glass plates, is a brittle, transparent, colourless, glassy body, soluble in water. During the drying process, especially if a little mineral acid is present, the acid is frequently converted into the meta modification. Solutions of the body are strongly acid to litmus paper, and have a sharp acid taste; they completely neutralise solutions of the alkalis and alkaline earths, and decompose carbonates. The salts of the alkaline earths are precipitated out of solution by alcohol; those of the alkalis are not precipitated under the same conditions, but yield peculiar milky or opalescent solutions from which arabic acid, with some of the alkaline salt, is precipitated on the addition of stronger acids. $BaSO_4$, PbS, and other sulphides, and some hydrates precipitated in solutions of arabic acid, cannot be filtered out, but pass, in greater part, through the filter. Fine animal charcoal is carried through in the same way (C.O'S.). Gum arabic prevents the precipitation of the alkaloids by phosphomolybdic acid, potassium-mercury iodide, and tannin (Lefort a. Thibault, *J. Ph.* [5] 6, 169). These are properties common to all the gum acids. The defining characters of arabic acid are its optical activity, viz. $[\alpha]_j = -26°$ to $-28°$, for solutions containing 5 to 6 grams dry substance in 100 c.c., and the composition of its neutral barium and calcium salts; in the dry state, the former contains 6·0 p.c. BaO and the latter 2·28 p.c. of CaO (O'S.). Solid gum roasted with oxalic acid yields metagummic acid (Frémy), this is dissolved by solutions of the alkalis and alkaline earths with the reproduction of arabic acid (*v.* Rhem. *D. P. J.* 216, 539). Gum arabic and tragacanth are rendered insoluble by potassium bichromate and light (Eder. *J. pr.* 19, 299). Gum, even in small quantities, injected into the blood diminishes the elimination of urine, large doses completely stop the secretion, with a marked increase of blood pressure (Richet a. Montard-Martin, *C. R.* 90, 88).

Reactions.—1. Heated with moderately strong *nitric acid*, arabic acid yields mucic (*v.* Kiliani, *B.* 15, 34), saccharic, oxalic, and tartaric (Liebig) acids; with fuming nitric acid it yields substitution products.—2. Gum heated in sealed tubes with *bromine* yields a colourless or yellowish liquid, probably $C_{12}H_{20}O_{10}Br_4$, which, when treated with silver oxide, lead oxide, or caustic soda, is converted into isodiglycolethylenic acid, $C_{12}H_{20}O_{12}$ (Barth a. Hlasiwetz, *A. Ch. Pharm.* 122, 96). It is possible some of the decomposition products of arabic acid would yield the same results. 3. Gum arabic or arabin when heated to 150° with 2 parts *acetic anhydride* yields tetracetyl-diarabin (?) $C_{12}H_{16}(C_2H_3O)_4O_{10}$; and, when heated to 180° with 6 to 8 parts of the anhydride, a body having the composition $C_{12}H_{15}(C_2H_3O)_5O_{10}$; these acetyl derivatives are white amorphous powders (Schützenberger a. Naudin, *A. Ch.* [4] 21, 235). These bodies are certainly not derived from arabic acid as a whole, but from some one of its decomposition products (C.O'S.).—4. *Pepsin*, in dilute HCl solution, acts on dextrorotatory gum acid, arabinose being amongst the products; *pancreatin* has no action (Fudakowski, *B.* 11, 1072). 5. (*a*) Gum arabic left for some time in contact with *sulphuric acid* is converted into dextrin (!) and, on boiling, yields a sugar probably identical with *galactose* (Berthelot, *C. O.* 21, 219). (*b*) Strong sulphuric acid converts a strong solution of gum in a few hours into metagummic acid; but gum arabic freed from lime by oxalic acid is not transformed in the same way (Frémy). (*c*) Pulverised gum arabic, triturated with strong sulphuric acid, yields sulphogummic acid and a peculiar gum resembling that produced from linen by the action of sulphuric acid (Braconnot) and not capable of fermenting with yeast (Guérin-Varry). (*d*) Arabic acid, digested with dilute sulphuric acid, yields a crystallisable sugar, a non-crystallisable one, and an acid the barium salt of which is insoluble in alcohol: gums from different sources yield these bodies in various proportions, some varieties yielding scarcely any of the crystallisable sugar (Scheibler, *B.* 6, 612). (*e*) A solution containing 30 grams arabic acid (pure), 100 c.c. water, and 2 grams sulphuric acid, yields, on digestion at 100° for 15 minutes, at least two sugars and a new acid the Ba salt of which is insoluble in alcohol: the following equations represent the change:—

$$\text{I. } \underset{\text{arabic acid}}{C_{89}H_{142}O_{74}} + H_2O = \underset{\alpha\text{-arabinosic acid}}{C_{83}H_{132}O_{69}} + \underset{\alpha\text{-arabinose}}{C_6H_{12}O_6}$$

$$\text{II. } C_{83}H_{132}O_{69} + H_2O = \underset{\beta\text{-arabinosic acid}}{C_{77}H_{122}C_{64}} + \underset{\alpha\text{- or }\beta\text{-arabinose}}{C_6H_{12}O_6}$$

$$\text{III. } C_{77}H_{122}O_{64} + H_2O = \underset{\gamma\text{-arabinosic acid}}{C_{71}H_{112}O_{59}} + \underset{\beta\text{-arabinose}}{C_6H_{12}O_6}$$

Continued digestion produces changes that may be represented as follows:—

III. IV. V. VI. VII. and VIII.

$C_{77}H_{122}O_{64} + 9H_2O = C_{41}H_{68}O_{37} + 6C_6H_{12}O_6$
θ-arabinosic acid, β-γ-δ-arabinose.

On further digestion we get:

IX. $C_{41}H_{68}O_{37} + H_2O = C_{35}H_{58}O_{32} + C_6H_{12}O_6$
ι-arabinosic acid δ-arabinose (?)

X. $C_{35}H_{58}O_{32} + H_2O = C_{29}H_{48}O_{27} + C_6H_{12}O_6$
κ-arabinosic acid. δ-arabinose (?)

XI. $C_{29}H_{48}O_{27} + H_2O = C_{23}H_{38}O_{22} + C_6H_{12}O_6$
λ-arabinosic acid δ-arabinose (?)

This last acid is very stable, resisting the action of a boiling 3 to 4 p.c. solution of sulphuric acid for a considerable time (O'Sullivan, *C. J.* 45, 41). α-arabinose is not yet fully described; β-arabinose[1] is Scheibler's arabinose, γ-arabinose is probably identical with galactose, and the remaining sugar or sugars are imperfectly described. These reactions convey some idea of the constitution of the gums of the arabin group, *i.e.* of those which are salts of a gum-acid with alkaline or alkaline-earthy bases, and enable us to understand some of the differences observed in their properties. Those bodies vary considerably in optical activity; this is due (*a*) to the varying proportions of different closely related acids they contain. O'Sullivan found the acid of some samples of gum arabic to consist almost wholly of arabic acid, whilst others contained also α-arabinosic acid, $[\alpha]_j = -36°$, and an acid ($C_{95}H_{152}O_{79}$), $[\alpha]_j = -23°$, with a $C_6H_{10}O_5$ group more than arabic acid. (*b*) To the character and position of the $C_6H_{10}O_5$ group in the acid from the $C_{23}H_{38}O_{22}$ body upwards. Kiliani (*l.c.*) shows that different varieties of gum yield, when oxidised with HNO_3, proportions of mucic acid varying between 14·3 and 38·3 p.c., thus indicating a difference in the number of galactose (γ-arabinose)-yielding groups they contain (see also Scheibler). And (*c*) possibly to the structure of the $C_{23}H_{38}O_{22}$ group itself. The gums, too, vary much in the character of the solutions they yield (Gm. 15, 194); some give a thin syrupy solution, others a thick and jelly-like one; this is due to the varying proportion of the acid naturally converted into the meta modification—the gums which yield the thinnest solutions are those which contain the greatest amount of ash. Gums from the same source have not always the same optical activity; Scheibler found the beet gum of one season +, and of another −; Kiliani states that East Indian gum, and gum arabic elect. are +, the samples of these gums examined by O'Sullivan were −; the sample of Australian gum examined by the former was +, that by the latter, inactive. From this it would appear that the same plant does not produce the same gum in every season, but, on the whole, it is fairly certain that the acids of all the gums are constituted in the same way as arabic acid described above.

Combinations.—The arabic salts of the alkaline earths are prepared by exactly neutralising moderately strong solutions of the pure acid with clear solutions of the earth the salt of which is required, precipitating with alcohol, treating the pp. with strong alcohol until it admits of being powdered, collecting the powder on a filter, pressing, and drying over sulphuric acid. The Ba salt contains $C_{89}H_{142}O_{74}BaO$ (6·0 p.c. BaO) and the CaO salt, $C_{89}H_{142}O_{74}CaO$ (2·28 p.c. CaO). When the syrupy solutions of these salts are allowed to dry spontaneously they yield glassy, transparent masses, like natural gums: the salts of the arabinosic acids yield similar bodies. C. O'S.

ARABITE $C_5H_{12}O_5$ which is probably $CH_2(OH).CH(OH).CH(OH).CH(OH).CH_2(OH)$. *Penta-oxy-n-pentane.* [102°]. Obtained by reduction of arabinose with sodium-amalgam, keeping the solution carefully neutralised. Small prisms or needles. V. sol. water and hot 90 p.c. alcohol, v. sl. sol. cold alcohol. Sweet taste. Does not reduce Fehling's solution. Does not lose water at 100° (diff. from sorbite) (Kiliani, *B.* 20, 1233).

ARABONIC ACID *v.* TETRA-OXY-VALERIC ACID.

ARACHIC ACID $C_{20}H_{40}O_2$. Mol. w. 312. [75·5°]. *Arachidic acid.*

Occurrence.—1. In the oil from the ground nut *Arachis hypogæa*, from which it is obtained after saponification (Gössmann, *A.* 89, 1).—2. In butter (Heintz, *P.* 90, 146).—3. As glyceryl ether in the fruit of *Nephelium lappaceum* (Oudemans, *J. pr.* 99, 407).

Formation.—1. By potash-fusion from brassidic acid (Goldschmiedt, *J.* 1877, 728).—2. From stearic acid by converting it into the corresponding alcohol, $C_{17}H_{35}CH_2OH$, and iodide $C_{17}H_{35}CH_2I$. The latter gives octadecyl aceto-acetic ether when treated with sodio-aceto-acetic ether, and alcoholic KOH thence produces arachic acid (Schweizer, *Ar. Ph.* [3] 22, 753).

Properties.—Small shining plates; v. sol. boiling alcohol, and ether; insol. water. Gives a nitro-, [70°], and an amido- [59°], arachic acid.

Salts.—(Scheven a. Gössmann, *A.* 97, 257). AgA′: prisms (from alcohol)—CuA'_2: needles (from alcohol)—BaA'_2: hardly soluble in alcohol. —SrA'_2—MgA'_2: crystalline powder (from alcohol).—KA′: usually gelatinous.

Methyl ether. [55°]. Scales (Caldwell, *A.* 101, 97); [53°] (Schweizer).

Ethyl ether. [49·5°]. (296°) at 100 mm.

Iso-amyl ether. [45°]. Scales.

Arachins. Prepared artificially by heating arachic acid with glycerin (Berthelot, *A. Ch.* [3] 47, 355); they are insol. ether. *Di-arachin* $C_3H_5(OH)(OC_{20}H_{39}O)_2$ melts at [75°].

Arachyl chloride $C_{20}H_{39}O.Cl$. [67°]. Unstable (Tassinari, *B.* 11, 2031).

Arachamide $C_{20}H_{39}O.NH_2$. [99°]. Prisms grouped in stars; insol. water, sol. hot alcohol (Gössmann a. Scheven, *A.* 97, 262).

Acetic-arachic anhydride $C_{20}H_{39}O.O.Ac$. [60°]. From AcCl and potassium arachate. Scales (from ether) (T.).

Valeric-arachic anhydride $C_{20}H_{39}O.O.C_5H_9O$ [68°] (T.).

ARALEÏN. The bark of *Aralia spinosa* contains a tannin which gives a green colour with Fe_2Cl_6, and a glucoside called araleïn. The latter is a neutral, light-yellow substance, sol. water and alcohol, insol. ether, benzene, and $CHCl_3$. Gives no pp. with lead acetate, $HgCl_2$, or $PtCl_4$. Boiling dilute HCl converts it into white araliretin, insol. water (Holden, *Ph.* [3] 11, 210).

---

[1] According to Kiliani (*B.* 20, 339a, 1233) the formula of arabinose is $C_5H_{10}O_5$; should this prove to be so, the formula of arabic acid and of the arabinosic acids must be diminished by a CH_2O group for every molecule of arabinose-yielding group they contain.

ARBOL-A-BREA RESIN. The product of a tree (*Canarium album*) growing in the Philippine Islands (Maujean, *J. Ph.* 9, 45; Bonastre, *J. Ph.* 10, 199). Baup (*J. pr.* 55, 83) finds four crystalline substances in it: Amyrin [174°]; Breïdin, S. ·39 at 20°; Breïn [187°]; and Bryoïdin [185°].

ARBUTIN $C_{12}H_{16}O_7$ ½aq. [166°].

Occurrence.—Together with methyl-arbutin in the leaves of the red bearberry, *Arctostaphylos Uva Ursi* (Kawalier, *A.* 82, 241; 84, 356), and in the leaves of a species of winter-green, *Pyrola umbellata* (Zwenger a. Himmelmann, *A.* 129, 203).

Preparation.—The aqueous infusion of the leaves is ppd. by lead acetate, excess of lead removed by H_2S, the filtrate evaporated and the arbutin extracted and crystallised by a mixture of ether (8 pts.) and alcohol (1 pt.). The product is a mixture of arbutin and methyl-arbutin, which can be separated by crystallisation from water (H. Schiff, *G.* 11, 99; 13, 538; *A.* 221, 365; *cf.* Habermann, *M.* 4, 753).

Properties.—Long glistening needles which melt at 165°, but, on second fusion, at 187° (H. Schiff, *B.* 14, 304; *A.* 206, 159). V. sol. alcohol and boiling water, v. sl. sol. ether. Its aqueous solution gives no pp. with lead acetate or subacetate. Does not reduce alkaline cupric solution. Dilute Fe_2Cl_6 gives a blue colour.

Reactions.—1. Split up by emulsin or by boiling dilute H_2SO_4 into hydroquinone and glucose (Strecker, *A.* 107, 229).—2. H_2SO_4 and MnO_2 form quinone.—3. Converted by Ag_2O into water and di-arbutin, an extremely soluble syrup, whence arbutin can be recovered by reduction with Zn and H_2SO_4 (Schiff, *A.* 154, 244).—4. *Chlorine* passed into an aqueous solution forms di-, and tri-chloro-quinones (Strecker, *A.* 118, 295).

Acetyl derivative $C_{12}H_{11}Ac_5O_7$. Plates or needles (from alcohol), insol. water.

Benzoyl derivative $C_{12}H_{11}Bz_5O_7$. Crystalline powder, sl. sol. alcohol.

Di-nitro-arbutin $C_{12}H_{14}(NO_2)_2O_7$. Golden needles (from water); insol. ether (Hlasiwetz, a. Habermann, *A.* 177, 343). Gives an orange pp. with lead subacetate. Boiling dilute H_2SO_4 gives di-nitro-hydroquinone. Converted by Ac_2O into $C_{12}H_9Ac_5(NO_2)_2O_7$.

Methyl-arbutin $C_{13}H_{18}O_7$ *i.e.* $C_6H_7O(OH)_4.O.C_6H_4.OMe$. [169°] (Michael); [175°] (Schiff). Occurs in nature associated with arbutin. Formed synthetically by the action of acetochlorhydrose upon potassium hydroquinone methyl ether, $KO.C_6H_4.OMe$ (Michael, *Am.* 5, 178; *B.* 14, 2097). Also from crude arbutin by converting the free arbutin into methyl-arbutin (by MeI and KOH) or into benzyl-arbutin (H. Schiff, *G.* 12, 464; *A.* 221, 366).

Properties.—Colourless silky needles, with bitter taste. Contain aq and melt at 169° (Michael); contain ½aq and melt at 175° (Schiff). Sol. water and alcohol, v. sl. sol. ether. Gives no blue colour with Fe_2Cl_6.

Benzyl-arbutin $C_{19}H_{22}O_7$ *i.e.* $PhCH_2O.C_6H_4O.C_6H_{11}O_5$ aq. [161°]. S. ·19 at 23°. From $PhCH_2Br$, commercial arbutin (containing methyl-arbutin), and KOH in boiling alcohol. Excess of KOH is removed by CO_2, and after evaporating and adding water, benzyl-arbutin is ppd. while methyl-arbutin remains in solution. Arborescent needles. Soluble in boiling water, very soluble in alcohol. Does not reduce Fehling's solution, except after short boiling with H_2SO_4 which splits it up into glucose and benzyl-hydroquinone. Gives on nitration yellow needles which are benzyl-nitro-arbutin, $C_{19}H_{21}(NO_2)O_7$, [143°], split up by dilute H_2SO_4 into glucose and benzyl-nitro-hydroquinone (Schiff a. Pellizzari, *A.* 221, 365).

Isoamyl-arbutin. From the mixture of arbutin and methyl-arbutin by amyl bromide and NaOH (S. a. P.). Needles. On decomposition gives iso-amyl-hydroquinone and glucose.

ARCHIL or *Orseille* is a purple dye obtained from various lichens (*Roccella*, *Lecanora*, and *Variolaria*) containing acids (*erythric*, *lecanoric*, *&c.*), which on decomposition yield orcin (*q. v.*) which is converted by air and ammonia into red orceïn. When K_2CO_3 or Na_2CO_3 as well as ammonia is added to the lichens litmus is produced.

ARGININE $C_6H_{14}N_4O_2$. Easily soluble in water; reacts alkaline. Occurs to the extent of about 3–4 p.c. in the young shoots of the lupine (*lupinus luteus*). The shoots are extracted with water; tannin and lead acetate are added to the extract; the filtrate is acidified with H_2SO_4, again filtered, and ppd. with phosphomolybdic acid; the pp. is washed and treated with cold milk of lime, and the solution of the base finally neutralised with HNO_3 and evaporated to crystallisation.

Salts.—$B'HNO_3$ ½aq: slender white soluble needles; with phosphomolybdic acid it gives a white pp. soluble in hot water; with picric acid a yellow crystalline pp. is formed on standing. — $B'HCl$: large crystals. — $B'_2Cu(NO_3)_2$ 3aq: formed by heating a solution of the nitrate with cupric hydrate; dark-blue prisms, sl. sol. cold water (Schulze a. Steiger, *B.* 19, 1177).

ARGOL. Crude acid potassium tartrate deposited from wine.

ARGYRÆSCIN $C_{27}H_{42}O_{12}$. A glucoside in the cotyledons of the horse-chestnut. Minute tables (from dilute alcohol). Split up by dilute HCl into argyræscetin $C_{21}H_{30}O_6$ and glucose. Potash produces propionic acid and æscinic acid (*q. v.*) (Rochleder, *J. pr.* 87, 1; 101, 415).

ARIBINE $C_{23}H_{20}N_4$. S. 12·9 at 23°. A base extracted by dilute H_2SO_4 from the bark of *Arariba rubra*, the solution being treated with lead acetate and the base dissolved in ether, from which it separates as anhydrous pyramids or (with 8 aq) as four-sided prisms. V. sol. water and alcohol, m. sol. ether (Rieth a. Wöhler, *A.* 120, 217). Salts.—$B''2HCl$.—$B''H_2PtCl_6$.—$B''H_2SO_4$.—$B''2H_2SO_4$.

ARICINE $C_{23}H_{26}N_2O_4$. [188°]. S. (ether) 5 at 18°. '*Cusconine*,' *Cinchovatine.* Yellow Cusco bark contains ·24 p.c. aricine and ·37 p.c. cusconine. Occurs also in bark of cinchona cupræa (Hesse, *Ph.* [3] 12, 517). Prisms (from dilute alcohol); insol. water, v. e. sol. chloroform, m. sol. ether, v. sl. sol. alcohol. Solutions are not fluorescent. Lævorotatory in alcoholic or ethereal solutions; its solution in dilute HCl is inactive. In a 1 p.c. ethereal solution $[\alpha]_D = -94·8°$; in a 1 p.c. alcoholic (97 p.c.) solution $[\alpha]_D = -54°$. Aricine is turned dark green by conc. HNO_3. Bleaching-powder and NH_3 only give a yellowish colour.

Salts. — $B'HCl$ 2aq. — $B'_2H_2PtCl_6$ 5aq. — HI. — $B'HNO_3$. — $B'_2H_2SO_4$: slender needles, n. sol. cold water.—$B'H_2SO_4$: small prisms, v. l. sol. cold water.—B'HOAc 3aq: grains, v. sl. ol. cold water.—$B'H_2C_2O_4$ 2aq: white prisms, uickly changing to rhombohedra, S. ·049, sl. ol. hot alcohol. — B'HSCy. — **Salicylate** $'C_7H_6O_3$ 2aq.

References.—Pelletier, *A. Ch.* [2] 42, 330; 1, 185; Pelletier a. Corriol, *J. Ph.* [2] 15, 575; everköhn, *Repert. f. Pharm.* 33, 357; Manzini, *Ph.* [3] 2, 95; Howard, *Ph.* [3] 5, 908; Hesse, . 166, 259; 181, 58; 185, 321; 200, 303.

ARNICIN $C_{20}H_{30}O_4$ (?). An amorphous substance present in the root, leaves, and blossoms *Arnica montana* (Walz, *N. Jahrb. Pharm.* , 175; 14, 79; 15, 329).

AROMATIC SERIES. Substances whose molecules contain a benzene nucleus are said to belong to the aromatic series.

Elements attached to a carbon atom belonging to the benzene nucleus are more firmly fixed than when attached to a carbon atom not in that nucleus: in the former case the derivative (called an *eso* derivative) has the character of a derivative of benzene, in the latter case the derivative (called an *exo* derivative) behaves like a fatty compound. Thus *exo*-chloro-toluene (benzyl chloride) $C_6H_5CH_2Cl$ behaves like ethyl chloride, being readily converted into an alcohol, amine, or cyanide, by treatment with KOH, NH_3, or KCN, respectively; while *eso*-chloro-toluene, $C_6H_4Cl.CH_3$, is not affected by these reagents.

It must, however, be added that the ease with which a given atom or radicle in the molecule of an aromatic compound may be displaced depends not only upon its position in relation to the carbon atoms but also upon the existence and position of other elements or radicles in the molecule. Thus *o*- and *p*-, but not *m*-, chloro-nitro-benzene are converted by hot aqueous otash into nitro-phenols, and by NH_3 into itro-anilines; while chloro-phenols and chloro-enzene sulphonic acids are converted into di-xy-benzenes by potash-fusion.

Halogens acting upon cold hydrocarbons in he presence of carriers (such as I) enter the enzene nucleus, but when acting alone upon ydrocarbons at 100° or upwards they enter a ide chain (*exo* position). Direct sunlight has he same effect as elevation of temperature, but its effect is entirely counteracted by the presence of iodine (Schramm, *B.* 18, 606). Halogens attack a benzene nucleus that already contains hydroxyl, amidogen, or SO_3H, with much greater vigour than when its carbon atoms are united only to hydrogen and carbon.

Conc. HNO_3 and conc. H_2SO_4 attack aromatic compounds, NO_2 and SO_3H displacing H in the nucleus; they do not act upon fatty compounds in this way.

The constitution of the molecule of benzene, and the methods by which the relative position of elements or radicles in the molecules of its derivatives have been determined will be discussed in another article, *v.* BENZENE.

Laws of Substitution.—I. When one of the ollowing radicles has displaced one of the atoms f hydrogen in the benzene molecule, forming he compound C_6H_5A, any new group on entering will take up a position *meta* to A. Here A may be CO_2H, SO_3H, or NO_2, and probably also CN, CHO, SO_2Ph, and $CO.CH_3$ (Hubner, *B.* 8, 873; Nölting, *B.* 9, 1797; *cf.* Armstrong, *C. J.* 51, 259; Morley, *C. J.* 51, 579).

II. If in a substituted benzene, C_6H_5B, the substituting element or radicle be not one of the [illegible], then any new group on entering will take up an *ortho* or a *para* position: usually chiefly *p* with a little *o*. Examples of B are NH_2, NHAc, OH, Cl, Br, I, CH_3 and all chains of carbon atoms except such as begin with CO.

These laws tell the chief product of the substitutio[illegible] of isomerides at variance wit[illegible] be formed.

The radicles that induce meta substitution are all composed of an element (N, C, or S) united to a chlorous group; CCl_3 is also a radicle of this kind, and it gives a *m*-nitro-derivative, but it also gives a *p*-chloro-derivative.

The radicles that induce *p* or *o* substitution are either single elements, or elements united to basylous elements or groups. The radicles CH_2Cl and $CHCl_2$ are intermediate in character; the latter appearing to resemble CCl_3, the former resembling CH_3. Armstrong points out that the radicles producing *m* derivatives are unsaturated, and might form additive compounds before substitution takes place.

Amido compounds in presence of excess of H_2SO_4 (20 pts.) when treated with the calculated quantity of HNO_3 dissolved in H_2SO_4, added at 0°, give chiefly meta-nitro derivatives, some of the *p*-nitro derivative being also formed. Examples: aniline, acetanilide, toluidine, xylidine, *p*-bromo-aniline (Nölting a. Collin, *B.* 17, 261), di-methyl-aniline, di-ethyl-aniline (Groll, *B.* 19, 198), ethyl-aniline (Nölting a. Strecker, *B.* 19, 546). The amount of meta-nitro derivative formed is increased by increasing the quantity of sulphuric acid present. In all these cases nitrogen is attached to a chlorous radicle, aniline sulphate being $C_6H_5N(O.SO_3H)H_3$, and might therefore be expected to produce a meta derivative. It is, however, curious that a solution of aniline sulphate in a small quantity of sulphuric acid gives very little *m*-nitraniline on nitration.

When a new element or radicle enters a benzene nucleus in which more than one H is already displaced if it can satisfy the requirements of each of the substituents already present it will do so; if not it obeys the most powerful substituent present. The following appears to be the order of priority, beginning with the strongest:

HO; NH_2; halogens; CH_3; other alkyls; NO_2; CO_2H and SO_3H. The conversion of *p*-nitro-phenol into $C_6H_3(OH)Br(NO_2)$ [1:2:4], and that of *o*-nitro-phenol into $C_6H_3(OH)Br(NO_2)$ [1:5:2], by the action of Br are instances where both NO_2 and OH are obeyed; but in the action of Br upon *p*-bromo-phenol and of HNO_3 upon $C_6H_3(OH)Cl_2$ [1:2:4] the new substituent obeys the stronger radicle, producing $C_6H_2(OH)Br_3$ [1:2:4:6] and $C_6H_2(OH)Cl_2(NO_2)$ [1:2:4:6] respectively.

When a hydrocarbon radicle is introduced by the agency of $AlCl_3$ it does not always follow the foregoing rule; thus *m*-xylene is the chief product of the action of MeCl upon benzene in presence of $AlCl_3$.

Differences between o, m, and p compounds.

Ortho, meta, and para compounds usually boil at about the same temperature, but the para compounds have the highest melting-points. The ortho compounds are usually the most, and the para compounds the least, volatile with steam. In the oxidation of ortho compounds the benzene ring is liable to be broken up, while in the meta and para compounds this is not the case (*v.* HYDROCARBONS). Ortho compounds readily give rise to products of condensation in which the side chains may be supposed to be joined in the form of a ring; this tendency is observed to some extent in the para series but not at all in the meta series. Thus by loss of H_2O *o*-amido-phenyl-glyoxylic acid gives isatin; *o*-amido-cinnamic acid gives carbostyril, *o*-oxy-cinnamic acid gives coumarin; phthalic acid gives phthalic anhydride.

o-nitraniline hydrochloride is readily decomposed by water, *p*-nitraniline hydrochloride less so, and *m*-nitraniline hydrochloride is hardly decomposed by water (Lellmann, *B.* 17, 2719). In general, the introduction of a radicle into the *m*-position produces less change in the properties of a compound than the introduction of the same radicle into the *o* and *p* position, and of the resulting derivatives the meta are the most stable. Thus *m*-xylene is oxidised with difficulty, while dilute HNO_3 readily converts *o*-, and *p*-, xylene into toluic acids. Ortho-, and para-, oxybenzoic acids are converted into phenol by heating with aqueous HCl in sealed tubes, while *m*-oxybenzoic acid, like benzoic acid itself, is unaffected. Ammonia converts *o*- and *p*- nitro-anisols into nitranilines, but does not affect *m*-nitro-anisol or anisol itself; similarly ammonia converts *o*-, and *p*-, bromo-nitro-benzenes into nitranilines, but does not affect *m*-bromo-nitro-benzene or bromo-benzene itself. Boiling alkalis convert *o*-, and *p*-, nitraniline into nitrophenols, but do not affect *m*-nitraniline or aniline. Aniline and *m*-nitraniline resemble one another in readily uniting with phenyl thio-carbimide (forming diphenyl-thio-urea and nitro-di-phenyl-thio-urea respectively), while *p*-, and *o*-, nitraniline require to be heated for some time with phenyl thio-carbimide before they will combine. Benzoic acid and *m*-oxy-benzoic acid are readily reduced by sodium-amalgam to benzyl alcohol and *m*-oxy-benzyl alcohol respectively, while *o*-, and *p*-, oxybenzoic acids are not attacked. Ortho- and para-nitro-acetanilide dissolve in conc. potash; the former is readily saponified by the potash, giving potassium acetate and *o*-nitro-aniline; a similar decomposition occurs with the latter, but with greater difficulty. Meta-nitro-acetanilide is insoluble in conc. potash, and is scarcely affected by it (Kleemann, *B.* 19, 336). The substitution of an atom of hydrogen in the nucleus by an atom of bromine is accompanied by absorption of heat; in an actual experiment this is not observed, being more than counterbalanced by the heat developed in the simultaneous formation of HBr (Werner, *Bl.* 46, 282).

Occasional reactions.

1. *Acetyl bromide* not only displaces H by Ac but sometimes even turns out an alkyl; thus it converts di-methyl-aniline and di-ethyl-aniline into methyl acetanilide, and ethyl-acetanilide respectively (Staedel, *B.* 19, 1947).—2. *Benzoyl chloride* sometimes behaves in the same way, converting di-methyl-aniline and di-ethyl-aniline into methyl-benzanilide and ethyl-benzanilide respectively.—3. *Nitric acid* in nitration sometimes turns out acetyl, converting ethyl acetanilide into $C_6H_3(NO_2)_2NEtH$ [1:3:4], and behaving similarly towards methyl acetanilide (Norton, *B.* 18, 1997). Nitric acid sometimes turns out bromine; thus it converts *p*-bromo-aniline into tri-nitro-aniline (picramide) (Hager, *B.* 18, 2578).—4. *Potash* converts di-nitro-di-methyl-aniline, $C_6H_3(NO_2)_2NMe_2$ [4:2:1] into di-nitro-phenol, di-methyl-amine being given off.

Molecular changes.

At high temperatures *o*-compounds may change to *p*-, and both *o*- and *p*- to *m*-. At 100° *o*-phenol-sulphonic acid changes to *p*-phenol-sulphonic acid. At 220° potassium salicylate changes to *p*-oxybenzoate, while sodium salicylate is not affected at that temperature. Resorcin is obtained by potash-fusion from benzene *p*-disulphonic acid, *p*-chloro-benzene sulphonic acid, and *o*- and *p*-bromo-phenol.

Methyl can pass from combination with nitrogen into the nucleus; thus dimethylaniline methylo-iodide at 220° gives *o*- and *p*- dimethyl toluidine, methyl-xylidine, and di-methyl-xylidine; while at 335° it gives ψ-cumidine, $C_6H_2Me_3NH_2$ (Hofmann, *Pr.* 21, 47).

Ethyl aniline hydrochloride at 320° changes similarly to ethyl-phenyl-amine, $C_6H_4EtNH_2$, while isoamyl-aniline hydrochloride becomes isoamyl-phenyl-amine, $C_6H_4(C_5H_{11})NH_2$ (Hofmann, *B.* 7, 526). In these cases it may be supposed that MeI, MeCl, EtCl, and $C_5H_{11}Cl$ respectively are split off and then attack the nucleus; this action of MeCl is seen in the conversion of xylidine hydrochloride into ψ-cumidine by heating with methyl alcohol at 280° (Hofmann, *B.* 13, 1730).

Conversion of fatty compounds into aromatic.

1. By passing acetylene (*q. v.*) through a red hot tube.—2. By heating acetone or allylene with sulphuric acid mesitylene is formed.—3. Uvitic acid, $C_6H_3Me(CO_2H)_2$ [1:3:5] is formed by boiling pyruvic acid with baryta.—4. Oxy-uvitic ether is formed by the action of chloroform on sodium aceto-acetic ether.—5. Succinylo-succinic ether from succinyl chloride, sodium, and succinic ether is di-oxy-di-hydro-terephthalic ether; when heated with KOH it gives hydroquinone. Hydroquinone is also formed when succinates are subjected to dry distillation.—6. Phloroglucin tri-carboxylic ether is formed by the action of sodium or of $ZnEt_2$ on malonic ether (Baeyer, *B.* 18, 3457; Lang, *B.* 19, 2937). 7. Tri-mesic ether is formed by the action of sodium on a mixture of formic and acetic ether (Piutti, *B.* 20, 537).—8. Hexyl iodide and bromine at 200° gives hexa-bromo-benzene (Krafft, *B.* 9, 1085; 10, 801).—9. K and CO combine, forming $C_6(OK)_6$ (Nietzki a. Benckiser, *B.* 18, 1833).

Conversion of aromatic compounds into fatty.

1. Carbonic, oxalic, and formic acids are products of oxidation of aromatic compounds.—

2. Benzene is converted by $KClO_3$ and HCl into $C_3H_3Cl_3O_3$, which is converted by baryta into fumaric acid.—3. Nitrous acid converts pyrocatechin in ethereal solution into dioxytartaric acid.—4. HCl and $KClO_3$ convert gallic acid into tri-chloro-glyceric acid.—5. Chlorine passed into a cold aqueous solution of phloroglucin gives dichloro-acetic acid (Hlasiwetz a. Habermann, *A.* 155, 132).

Aromatic acids. The principal aromatic acids are those containing SO_3H and those containing CO_2H. The former will be discussed as SULPHONIC ACIDS, the latter will be briefly characterised here (*v.* also ACIDS, AMIDO-, BROMO-, CHLORO-, IODO-, and NITRO-acids).

Formation.—1. By oxidation of homologues of benzene or derivatives of such homologues. $K_2Cr_2O_7$ (2 pts.), H_2SO_4 (3 pts.), and water (3 to 5 pts.), is a convenient mixture for the purpose; but it converts all side chains into carboxyls, thus *m*- and *p*- xylene become iso-, and tere-, phthalic acids, while mesitylene becomes trimesic acid. Dilute HNO_3 (S.G. 1·2) and aqueous $KMnO_4$ oxidise more gradually, attacking one side chain at a time, thus converting *o*- and *p*-xylene into *o*- and *p*- toluic acid and mesitylene nto mesitylenic acid.—2. By passing CO_2 over a mixture of a bromo-derivative and sodium: $C_6H_5Br + CO_2 + Na_2 = C_6H_5CO_2Na + NaBr$(Kekulé, *A.* 137, 178).—3. By heating a bromo-derivaive with chloroformic ether and sodium, thus: $C_6H_5Br + ClCO_2Et + Na_2 = C_6H_5CO_2Et + NaCl + NaBr$ (Wurtz, *A. Suppl.* 7, 125).—4. By the ction of $COCl_2$ or CO_2 on aromatic hydrocarbons n presence of $AlCl_3$ (Friedel a. Crafts, *v.* ALUINIUM CHLORIDE, p. 147) the product being reated with water. The amides may be prouced in a similar way by using $Cl.CO.NH_2$ nstead of $COCl_2$ (Gattermann a. Schmidt, *B.* 20, 58).—5. By heating sulphonates with sodium formate: $PhSO_3K + HCO_2Na = Ph.CO_2Na + HSO_3K$ V. Meyer, *A.* 156, 273).—6. By saponification of itriles. The nitriles may be obtained either by eating sulphonates or *exo*-chloro derivatives ith potassium cyanide or by heating thio-carimides with copper (Weith, *B.* 6, 212). Nitriles ay also be obtained by distilling the formyl erivatives of amines with zinc-dust, *e.g.*: $hNH.CHO = H_2O + PhCN$.—7. By oxidation of cohols or aldehydes.—8. Aromatic acids conining carboxyl in the side chain can be prered by synthesis with aid of aceto-acetic ether *.v.*) or of malonic ether (*q. v.*).—9. Oxy-acids are formed by boiling diazo-acids with water, or by potash-fusion from chloro-, bromo-, iodo-, or sulpho-, acids.—10. By passing CO_2 into sodium phenols at 180° or potassium phenol; in the former case CO_2H takes up a position ortho to the hydroxyl. Potassium phenol at 140° gives salicylic acid, but at 170°-200° it gives *p*-oxy-benzoic acid. The reaction takes place in two stages:

$$C_6H_5.O.Na + CO_2 = C_6H_5.O.CO_2Na;$$
$$C_6H_5.O.CO_2Na = C_6H_4(OH).CO_2Na$$

v. OXY-BENZOIC ACIDS).—11. By heating phenols with dilute alcoholic solution of CCl_4 and NaOH at 100°: $C_6H_5OH + CCl_4 + 6NaOH = C_6H_4(ONa)CO_2Na + 4NaCl + 4H_2O$ (Tiemann a. Reimer, *B.* 9, 1285). **The carboxyl takes up positions para and ortho to the hydroxyl.—12. Perkin's synthesis of cinnamic acid and its homologues is described and discussed in the article on ALDEHYDES.—13. Resorcin and its homologues are converted into (1, 3, 4) and** 1, 3, 2) di-oxy-benzoic acids and their homologues by heating with ammonium carbonate and water; while hydroquinone and its homologues heated with potassium bicarbonate, water, and a little K_2SO_3 give (1, 4, 2) di-oxy-benzoic acid and its homologues (Senhofer, *Sitz. B.* 80, 504; 81, 430, 1044; *M.* 2, 448).

Reactions.—1. The aromatic acids are subject to the general laws governing substitution in the benzene nucleus.—2. They are usually sl. sol. water but v. sol. alcohol and ether. The homologues of benzoic, and of salicylic, acid are volatile with steam, *m*-, and *p*-, oxy-benzoic acids are not volatile with steam. Salicylic acid and its homologues are soluble in chloroform, *p*-oxy-benzoic acid and its homologues are not. Ortho-oxy-acids are also characterised by giving a violet colouration with Fe_2Cl_6.—3. Ortho-oxy-acids of the form $C_6H_4(OH).CH_2.CO_2H$ or $C_6H_4(OH).CH_2.CH_2.CO_2H$ have a tendency to produce anhydrides or lactones; ortho-amido acids of the form $C_6H_4(NH_2).CH_2.CO_2H$ or $C_6H_4(NH_2).CH_2.CH_2.CO_2H$ readily form anhydrides, similarly called lactams:  $C_6H_4<\genfrac{}{}{0pt}{}{CH_2}{NH}>CO$, or lactims:  $C_6H_4<\genfrac{}{}{0pt}{}{CH_2}{N}\geqslant C.OH$.—4. Benzene is produced by fusion with NaOH from benzoic acid (75 p.c.), trimellitic acid, hydrocinnamic acid, and cinnamic acid (50 p.c.); a little diphenyl is also formed. Fusion with NaOH converts *o*-, and *p*-, oxy-benzoic acids into phenol (50 to 60 p.c.); protocatechuic acid into resorcin (50 to 60 p.c.); (1, 3, 5)-di-oxy-benzoic acid into resorcin (60 p.c.), phloretic acid and *p*-coumaric acid into *p*-oxy-benzoic acid and finally into phenol; oxy-terephthalic acid into salicylic and *p*-oxy-benzoic acids, and finally into phenol (Barth a. Schreder, *B.* 12, 1255).

Aromatic bases. The preparation and properties of the aromatic bases have been discussed in the article on AMINES. They may be divided into two classes according as the nitrogen is attached to carbon in a benzene nucleus or in a side chain; bases of the latter form resemble fatty amines. Amines containing amidogen attached to the benzene nucleus are weakened in basic power by introduction of nitroxyl or halogens into the nucleus, more especially if these radicles do not occupy a position meta to the amidogen. Trichloraniline, dinitraniline, and trinitraniline do not combine with acids; the latter is even saponified by potash with formation of trinitrophenol.

ARSENATES. Salts of arsenic acid, *v.* ARSENIC, ACIDS OF, p. 305.

ARSENIC. As (*Arsenicum, Regulus arsenici,* *ἀρσενικόν.* By the term *σανδαράκη* Aristotle seems to mean a compound of arsenic and sulphur, called *ἀῤῥενικόν* by Theophrastus). At. w. 74·9. Mol. w. 299·6; 149·8 at c. 1700° (Biltz a. Meyer, *B.* 22, 725). Melts only under great pressure (Landolt; also Mallet, *C. N.* 26, 97). S.G. 5·23 to 5·76: pure, crystalline $\frac{14°}{14}$ 5·726-5·728; grey, pearly crystals $\frac{14°}{14}$ 4·71 (Bettendorff, *A.*

144. 110); amorphous $\frac{14^{\circ}}{14}$ 4·710–4·716 (*ibid. l.c.*); fused $\frac{19^{\circ}}{19}$ 5·709 (Mallet, *C. N.* 26, 97). V.D. 147·2 at 860° (Deville a. Troost, *C. R.* 56, 871); 153·7 at 640–670° (Mitscherlich, *A.* 12, 159). S.H. crystallised, ·083; black, amorphous, ·0758 (Bettendorff a. Wüllner, *P.* 133, 293). C.E. (linear at 40°) ·00000559 (Fizeaux, *C. R.* 68, 1125). E.C. (Hg at 0° = 1) 2·679 at 0°, 1·873 at 100° (Matthiessen a. Bose, *T.* 152, 1). S.V.S. cryst. 13·1; amorph. 15·9. $\frac{\mu_A - 1}{d}$ × at. wt. 15·4 (Gladstone, *Pr.* 18, 49). Chief lines in emission spectrum, *v.* Huntington, *P. Am. A.* [2] 9, 34; Hartley a. Adeney, *T* 1884. 121.

Occurrence.—Found native, but more frequently associated with other metals and sulphur, in widely distributed ores. Obtained as a principal product chiefly from *native arsenic*, *arsenical iron* $FeAs_2$ and Fe_4As_3, and *arsenical pyrites* $FeAsFeS_2$; obtained as a secondary product from *smaltine*, *cobalt glance*, *arsenical cobalt*, *nickel glance*, many *fahl-ores*, &c. Occurs also in ferruginous deposits of certain mineral waters (Will, *A.* 61, 192); in nearly all iron ores (Walchner, *A.* 61, 205); in soils, from the weathering of iron pyrites (Sonnenschein, *Ar. Ph.* [2] 143, 245); in the residue obtained by evaporating sea water (Daubrée, *Ann. M.* [4] 19, 669); frequently found in metallic bismuth (Schneider, *J. pr.* [2] 20, 418); in various kinds of pyrites, and hence in most samples of commercial sulphuric acid, and in many substances in the manufacture of which this acid is used (*v.* H. A. Smith, *P. M.* [4] 44, 370).

Preparation.—On the large scale by heating to redness, out of contact with air, arsenical iron or arsenical pyrites; arsenic sublimes; iron, or ferrous sulphide, remains. Prepared in small quantities at a time by heating As_4O_6 with powdered charcoal, or with 'black flux,' in crucibles covered with conical iron caps. Also by heating As_2S_3 with charcoal, an alkaline carbonate, and KCN. Purified by resublimation after mixing with powdered charcoal; or by heating with a little I (Ludwig, *Ar. Ph.* [2] 97, 23); or by boiling with moderately conc. K_2CrO_4Aq acidified with H_2SO_4 (Böttger, *J. pr.* [2] 2, 131). Arsenic was first prepared from arsenious acid in 1694 by Schröder; its chemical nature was further investigated by Brand (1733), Macquer (1746), Manget (1773), and others. Scheele discovered arsenic acid and arsenuretted hydrogen in 1775.

Properties.—Very brittle, steel grey, lustrous; crystallises by sublimation in hexagonal rhombohedra isomorphous with Sb and Te; $a : c = 1 : 1·4025$. H = 3·5. When As is sublimed in a rapid H stream in a glass tube the sublimate nearest the heated part of the tube consists chiefly of rhombohedra, that farther from the hottest part but still on a warm portion of the tube (210°–220°) of black amorphous As, while the coolest part of the tube is filled with yellow fumes which condense to grey crystals (Bettendorff, *A.* 144, 110). Black amorphous As is also obtained by condensing As vapour at a fairly high temperature; by decomposing As compounds by heating in glass tubes to moderately high temperatures (*e.g.* AsH_3), or by heating with reducing agents (*e.g.* As_4O_6 with C); or by reduction of As compounds in the wet way (Engel, *C. R.* 96, 497). As can be obtained in regular octahedra by heating a mixture of much H with a little AsH_3 (Cooke, *Am. S.* [2] 31, 91). Amorphous As is changed to crystalline by heating for some time at 310° (Engel, *C. R.* 96, 1314); by heating to 358°–360° (Bettendorff, *A.* 144, 110). Amorphous As when subjected to a pressure of 6500 atmospheres acquires metallic lustre and its S.G. increases (Spring, *B.* 16, 326). The vapour of As is citron-yellow (Le Roux, *C. R.* 51, 171). The spectrum of As shows lines in the orange (6169·5), yellow, and green (5331) (Thalen, *A. Ch.* [4] 18, 244); also many more refrangible lines (*v.* Hartley, *T.* 1884. 124). As combines with Cl and O with production of heat; $[As, Cl^3] = 71,390$; $[As^2, O^3] = 154,670$; $[As^2, O^3, Aq] = 147,120$; $[As^2, O^5] = 219,380$; $[As^2, O^5, Aq] = 225,380$ (Thomsen). As volatilises at a dark red heat without previous fusion at ordinary pressures. The molecule of As is tetratomic (As_4); the atom is trivalent in gaseous molecules (AsH_3, $AsCl_3$, &c.). The atomic weight has been determined (1) by analysing, and determining V.D. of, various gaseous compounds, AsH_3, $AsCl_3$, AsI_3, As_4O_6, &c.; (2) by determining S.H. of As; (3) by comparing isomorphous compounds of As, Sb, and Bi, arsenates with phosphates and vanadates, &c. (Wallace, *P. M.* [4] 18, 279; Dumas, *A. Ch.* [3] 55, 174; Kessler, *P.* 95, 204).

As is insoluble in alcohol and ether, but is said to be dissolved by certain oils. It oxidises fairly rapidly in air at ordinary temperatures; heated in air, it burns to As_4O_6 with a bluish flame; is oxidised by nitric and sulphuric acids, and by fusion with alkalis. As forms two series of compounds, of which As_4O_6 and As_2O_5 are representatives.

In many of its physical properties As is metallic, but in its chemical relations it is decidedly non-metallic or negative. Exhibits allotropy; oxides are acid-forming (*v.* ARSENIC, OXIDES OF; also ARSENIC, ACIDS OF); at the same time As_4O_6 appears to react with SO_3 to form a salt, and with $KH.C_4H_4O_6$ to form a compound analogous with tartar emetic, and with conc. HClAq to form $AsCl_3$ (*v.* ARSENIOUS OXIDE, under ARSENIC, OXIDES OF). Arsenious acid is unknown, and an aqueous solution of the oxide behaves towards alkalis as a very feeble salt-forming compound; but arsenic acid is as strong an acid as phosphoric, their relative affinities are nearly equal (*v.* AFFINITY, p. 67). The haloid compounds of As do not show any marked tendencies to form double salts. The hydride AsH_3 does not combine with acids, as NH_3 and PH_3 do; but at the same time compounds belonging to the form AsR_4X, where R is an alcoholic radicle C_nH_{2n+1}, and X is a halogen or even OH, are known (*v.* ARSENIC COMPOUNDS, ORGANIC). For a fuller discussion of the chemical relations of arsenic *v.* arts. BISMUTH, CHEMICAL RELATIONS OF; and NITROGEN GROUP OF ELEMENTS.

Reactions.—**1.** *Hydrochloric acid*, no action in absence of air; in presence of air a little $AsCl_3$ is formed.—**2.** *Nitric acid* and *aqua regia* react with production of much heat; oxides of N,

As_4O_6, and H_3AsO_4, are formed.—3. Hot. conc. *sulphuric acid* evolves SO_2 and forms As_4O_6.—4. *Molten potash* or *soda* produces an arsenite and H.—5. *Molten nitre* or *potassium chlorate* produces potassium arsenate; the action is more or less explosive.—6. *Solution of sulphur dioxide* reacts, when heated with As in a closed tube to 200°, to produce As_4O_6, S, and H_2SO_4Aq, but no sulphide of As (Geittner, *J.* 1861. 143).—7. *Ammonia solution* is without action on As.

Combinations.—1. With *nascent hydrogen* AsH_3 and AsH are formed (*q. v.*).—2. With *chlorine*, *bromine*, or *iodine*, $AsCl_3$, $AsBr_3$, or AsI_3 (*q. v.*) is produced.—3. With *fluorine* (action of HF on As_4O_6) AsF_3 is formed (*q. v.*).—4. With *oxygen* As combines to form As_4O_6 (*q. v.*); As_2O_5 (*q. v.*) is produced by heating one of its hydrates.—5. The sulphides As_2S_2 and As_2S_3 and As_2S_5 (*q. v.*) are produced by heating together arsenic and *sulphur*; the sulphide As_2S_5 is, however, best obtained by decomposing solutions of alkaline sulpharsenates by acid.—6. *Tellurium* combines with arsenic to form As_2Te_2 and As_2Te_3, when the two elements are melted together in the required proportions (Oppenheim, *J. pr.* 71, 266).—7. When arsenic is melted with *sulphur and selenion* in the proportions represented by the formulæ As_2SeS_2 and As_2SSe_2, two bodies having the compositions indicated are obtained. The first is a lustrous red semi-transparent mass from which the whole of the Se separates out after some days. This body is easily soluble (when powdered) in NH_4HSAq. The body As_2SSe_2 is a crystalline opaque solid which may be distilled unchanged; it is less easily soluble in NH_4HSAq than As_2SeS_2 (v. Gerichten, *B.* 7, 29).—8. Arsenic appears to be incapable of combining with *phosphorus* directly [older experiments by Landgrebe (*S.* 60, 184) probably yielded only a mixture of P and As]; but if AsH_3 is led into PCl_3, or PH_3 into $AsCl_3$, a red-brown solid is obtained (after drying it appears as a darker powder without lustre) which is insoluble in alcohol, ether, and $CHCl_3$, but fairly soluble in CS_2. This solid is PAs; it is changed by water into $P_2As_3O_2$ with which chlorine reacts to produce $AsCl_3$ and $POCl_3$. The compound PAs is rapidly oxidised by concentrated HNO_3, less rapidly by dilute HNO_3, giving H_3AsO_4 and H_3PO_4; solutions of KOH, NH_4OH, or $Ba(OH)_2$, easily decompose PAs rapidly when warm) producing PH_3, AsH_3, H_3PO_2, H_3AsO_3, and As. Heated in air PAs burns o As_2O_3 and P_2O_3; heated in absence of air, or n CO_2, phosphorus sublimes and then arsenic. The reactions of $P_2As_3O_2$ are very similar to hose of PAs (*v.* Janowsky, *B.* 6, 216; 8, 1636).—. Arsenic forms *alloys* with many *metals*. Some f these are produced by very strongly compressing the constituents (Spring, *B.* 16, 324). These alloys are generally brittle, they are only partially, in many cases not at all, separated into their constituents by the action of heat out of contact with air; they are generally oxidised to arsenates, and oxides of the metals, by fusion with nitre; fused with alkaline carbonates and ulphur, thio-arsenite or thio-arsenate of the alkali metal is generally produced, and the metals formerly alloyed with the arsenic are completely eparated as sulphides. Arsenides of heavy metals are scarcely if at all attacked by nitric acid or aqua regia. Many alloys of arsenic are definite compounds; several of them occur native as minerals (*v.* Winkler, *J. pr.* 91, 193; Sénarmont, *A. Ch.* 80, 221; Rammelsberg, *P.* 128, 441). The alloys with *cobalt*, which are brittle and iron-grey in colour, are formed, with production of heat, by melting the elements together. CoAs occurs native as *Smaltine*; it always contains more or less iron and nickel replacing part of the arsenic. Co_2As_3, generally containing more or less iron, also occurs native as *Skutterudite*, or *Modumite*. Arsenic alloys with *copper* to form white solids which tarnish in the air. According to Lippert (*J. pr.* 81, 168) the grey deposit obtained by heating copper in an HCl solution of arsenious oxide is Cu_3As_2; when this body is heated in hydrogen Cu_6As remains. The compounds Cu_3As, Cu_6As, and Cu_9As, occur native as *Domeykite*, *Algodonite*, and *Darwinite*, respectively. The alloys of arsenic and *iron* are brittle solids formed by melting the elements together; $FeAs_2$ and Fe_4As_3 occur native as *Arsenical iron*, sometimes containing Ag, Au, and Cu. Arsenic alloys with *lead* to form brittle solids. With *nickel*, arsenic alloys easily; Ni_2As is obtained by melting the elements together. The minerals *Copper-nickel* NiAs, and *Cloanthite* $NiAs_2$, occur native; they contain varying quantities of Sb, Fe, Pb, Co, and Cu. A lustrous crystalline alloy Ni_3As_2 is obtained by reducing arsenate of nickel by charcoal at a high temperature; Ni_3As is said to be formed when KCN, As, and NiO are fused together (Descamps, *C. R.* 86, 1065). Arsenic also alloys, with production of much heat, with *potassium* and *sodium*; the products are decomposed by water with formation of KOH (or NaOH)Aq, AsH_3, and As. An alloy of 15 parts *tin* and 1 part arsenic forms large leaf-like crystals. Arsenic is not much used in technical chemistry; the alloy with lead is employed in making shot. Arsenic appears to form alloys with several other metals, especially Hg (?) Pd and Pt. By strongly compressing (6500 atmos.) As with various metals, Spring (*B.* 16, 326) obtained several well-defined alloys, *e.g.* Zn_3As_2, Cu_3As_2, &c. &c.

Detection.—In dry way. Arsenic heated with slight access of air volatilises with a garlic-like odour (probably due to a little As_4O_6) and condenses on cooling as a lustrous black deposit, which is easily converted into a white crystalline sublimate (As_4O_6) by heating in presence of plenty of air. Sulphides or oxides of arsenic, and the salts of arsenious and arsenic acid, yield sublimates of black amorphous arsenic when heated with an alkaline carbonate alone or mixed with charcoal or KCN (*v.* Fresenius, *A.* 49, 301; Rose, *P.* 90, 193). Oxide of arsenic heated with much $NaC_2H_3O_2$ in a tube closed at one end yields cacodyl oxide, recognised by its foul smell. In wet way. I. *Arsenious compounds.* (i.) *Sulphuretted hydrogen* passed into a solution of As_4O_6, or an arsenite, acidified with HCl, forms a bright yellow pp. of As_2S_3, soluble in NH_4OH, NH_4SH, and $(NH_4)_2CO_3$, solutions, and reprecipitated by HCl. As_2S_3 is said to be soluble in a considerable quantity of boiling water and in boiling dilute HCl (Odling, *Guy's Hosp. Rep.* [3] 1, 239). (ii.) *Neutral solution of silver nitrate* produces a canary-yellow pp. of Ag_3AsO_3 easily soluble in most acids and in ammonia. (iii.) ***Neutral solution of copper sulphate*** precipitates green $CuHAsO_3$ (Scheele's green) easily soluble in acids and in ammonia. (iv.) *Reinsch's test* (*J. pr.* 24, 244). A warm solution of an arsenious compound acidified with HCl deposits a film of arsenic on a piece of bright *copper* kept in contact with it for some time; this deposit may be oxidised to As_4O_6 by heating in air (*v. supra*). The deposit consists of. As_2Cu_5 according to Lippert (*J. pr.* 81, 168). Arsenic compounds may be detected by Reinsch's test, if present in considerable quantity (Werther, *J. pr.* 82, 286), even in small quantity if heated for some time with HCl (Reinsch, *N. J. P.* 16, 135); the HCl used must not be weaker than S.G. 1·1 (Bettendorff, *Z.* [2] 5, 492). According to J. M. Scherer (*Fr.* 3, 200) the delicacies of the wet tests are as follows; $AgNO_3$ detects $\frac{1}{200,000}$ part of As, $CuSO_4$ detects $\frac{1}{13,500}$ part, H_2S detects $\frac{1}{610,000}$ part, and Reinsch's test detects $\frac{1}{120,000}$ part, or after boiling for $\frac{1}{4}$ hour $\frac{1}{250,000}$ part of As. (v.) *Marsh's test.* When *hydrogen is evolved in contact* with an acidified solution of an arsenious compound, whether by the action of zinc (Marsh, *B. J.* 17, 191; 20, 190; 22, 175), magnesium (Roussin, *J.* 1866. 801), or the electric current (Bloxam, *C. J.* 13, 14), arsenic trihydride is evolved; arsenic may be separated by passing the gas through a glass tube heated at one part, or by burning the gas in a limited supply of air and presenting a cold surface of porcelain, or thick platinum (Davy, *J.* 1858. 609), on which the arsenic condenses. The deposit of arsenic is easily soluble in HNO_3, S.G. 1·2 to 1·3; the solution contains arsenious acid (which on boiling for some time is changed to arsenic acid), it gives the characteristic yellow pp. of Ag_3AsO_3 (*v. supra*); the deposit of arsenic is also easily soluble in aqueous NaClO free from Cl; if the deposit is warmed in dry H_2S yellow As_2S_3 is produced which is not changed when warmed in a current of *dry* HCl gas. Arsenious hydride passed into aqueous $AgNO_3$ precipitates Ag, but the whole of the As remains in solution along with HNO_3 formed in the reaction, and may be detected by filtering and carefully neutralising the filtrate with dilute ammonia, when yellow Ag_3AsO_3 is produced. [SbH_3 precipitates Ag from $AgNO_3$ but the whole of the Sb is at the same time thrown down; the deposit of Sb obtained by heating, or burning, SbH_3 is insoluble in NaClO solution free from Cl, and is much less soluble than As in HNO_3Aq of S.G. 1·2 to 1·3; moreover, the solution in HNO_3Aq gives no reaction with $AgNO_3Aq$ and ammonia. The reactions of the two gases towards $AgNO_3$ solution affords a means for separating them (Husson, *C. R.* 83, 199).] The electrolytic method of preparing AsH_3 has the advantages (*a*) of avoiding the use of zinc which generally contains arsenic; (*b*) of not interfering with the subsequent testing for other metals; (*c*) of allowing the separation of antimony if present—this is done by adding a little H_2S to the liquid, whereby As_2S_3 and Sb_2S_3 are formed; the former is easily, the latter not at all, decomposed by the current (Bloxam, *C. J.* 13, 14, 338). The presence of HNO_3 prevents the formation of AsH_3 (Blondlot, *J.* 1863. 681). (vi.) ***Bettendorff's test*** (*Z.* [2] 5, 492). ***Stannous chloride in fuming HCl***, added to a solution of As_4O_6 or As_2O_5 in the same acid, precipitates metallic As mixed with a little SnO_2. This test is said to be extremely delicate; it may be used to detect As in presence of Sb, also to remove As from HClAq (*v.* also Hager, *J.* 1870. 966). II. *Arsenic compounds.* (i.) *Neutral silver nitrate* precipitates red-brown Ag_3AsO_4 soluble in NH_4OHAq and in HNO_3Aq, but less soluble in HNO_3Aq than Ag_3AsO_3, so that if $AgNO_3$ is mixed with a solution of an arsenite and an arsenate in HNO_3Aq, and NH_4OHAq is then added drop by drop, Ag_3AsO_4 is precipitated before Ag_3AsO_3; a solution of arsenic acid in nitric acid is precipitated by $AgNO_3$ if a few drops of a concentrated solution of an alkaline acetate are added (Avery, *Am. S.* [2] 47, 25). (ii.) *Neutral copper sulphate* precipitates bluish green $CuHAsO_4$ soluble in HNO_3Aq and in NH_4OHAq. (iii.) *An alkaline solution of magnesium sulphate*, containing enough NH_4Cl to prevent precipitation of magnesia, precipitates white $Mg(NH_4)AsO_4$; delicacy 1 part of As in 56,000 (Levol, *B. J.* 28, 130) (*cf. Estimation of Arsenic*). (iv.) *Ammonium molybdate* in excess precipitates bright yellow arseno-molybdate of ammonium from warm (not cold) solutions of arsenates containing HNO_3. (v.) *Sulphuretted hydrogen* slowly reduces arsenic to arsenious acid and then (in presence of HCl) precipitates yellow As_2S_3 mixed with S. (vi) *Marsh's test.* Arsenic compounds in solution are reduced to AsH_3 by hydrogen evolved in contact with the solution; the reduction takes place under the same conditions as, but more slowly than, the reduction of arsenious compounds (*v. supra*).

Arsenic may be reduced to arsenious compounds by such deoxidising agents as sulphurous or phosphorous acid; the reverse change may be accomplished by heating with HNO_3Aq, HClAq and $KClO_3$, &c.

Detection in cases of poisoning.—Arsenious oxide or white arsenic is the usual form in which the poison is administered. Because of the insolubility of this compound, small solid particles of it may sometimes be picked out of the food or contents of the intestine; these should be tested by reduction to metallic arsenic, &c., in the dry way. The poison is, however, usually mixed with large quantities of organic matter which must be removed or destroyed, after which the arsenic may be ppd. as As_2S_3 by long-continued passage of H_2S, the pp. may then be dissolved in warm HClAq with a crystal of $KClO_3$, free chlorine removed by warming, or the pp. may be dissolved in warm H_2SO_4Aq, and Reinsch's, or better Marsh's, test used for detecting the arsenic in solution. The organic matter may be removed by diffusion (Graham); or it may be destroyed by (*a*) treatment with warm concentrated H_2SO_4Aq, (*b*) warming with HClAq and crystals of $KClO_3$ added from time to time, (*c*) warming with HClAq and a little HNO_3Aq, (*d*) passing Cl into the liquid instead of adding $KClO_3$, (*e*) heating with HNO_3Aq till the residue is semi-pasty and yellow, adding NaOHAq till the acid is neutralised, mixing with powdered Na_2CO_3 and a little $NaNO_3$, drying in a crucible and gradually heating until the mass fuses (Wöhler; *v.* also Meyer, *A.* 66, 237). All reagents used must be carefully freed from arsenic; a blank experiment should be conducted with the reagents alone.[1] (Buiz a. Schulz find that certain parts of the animal organism reduce As_2O_5 and also oxidise As_4O_6; they think that the poisonous effects of As_4O_6 are due to rapid deoxidation and reoxidation, *v. B.* 12, 2199; 14, 2400; 15, 1388.)

Estimation.—I. *Gravimetric methods.* (i.) As magnesium-ammonium arsenate. Solution of $MgSO_4$ is mixed with excess of NH_4OHAq and allowed to stand for 12 hours; this liquid is added to the solution containing arsenic acid to which an excess of NH_4OHAq has previously been added. After some time the pp. is collected on a weighed filter, washed with ammonia-water, and either (*a*) dried *in vacuo* over H_2SO_4, when it has the composition $Mg.NH_4.AsO_4.6H_2O$, or (*b*) dried at 100° to 110° whereby $2(Mg.NH_4.AsO_4)H_2O$ is produced, or (*c*) strongly heated over a Bunsen lamp (temperature being gradually raised) whereby $Mg_2As_2O_7$ is formed. Method *c* is recommended by Puller (*Fr.* 10, 41), who states that the best means of converting As_2S_3 into arsenic acid is treatment with red fuming HNO_3 (*v.* also Rammelsberg, *B.* 7, 544; Wood, *Am. S.* [3] 6, 368; Macivor, *C. N.* 32, 283).—(ii.) As arsenious sulphide. Arsenates are reduced to arsenites by SO_2 solution; the arsenious solution is acidified with HClAq, and As_2S_3 is ppd. by long-continued passage of H_2S; the pp. is washed with CS_2 to remove any S which it may contain, collected on a weighed filter, and dried at 100°-110° (Puller, *Fr.* 10, 41). — (iii.) As uranyl pyroarsenate. Uranic acetate in presence of ammonium salts pps. ammonium-uranyl arsenate $NH_4.UO_2.AsO_4 + Aq$, insoluble in water and acetic acid, but soluble in mineral acids. When this pp. is washed, dried, and gradually heated to bright redness, the pyroarsenate $(UO_2)_2As_2O_7$ is obtained. This method is recommended by Puller (*l.c.*); As_2S_3 may be dissolved in HClAq + $KClO_3$, and the As ppd. after adding $NH_4.C_2H_3O_2$ and $H.C_2H_3O_2$ aq.

II. *Volumetric methods.* — (i.) By iodine. Arsenious, is converted into arsenic, acid, by iodine in presence of alkali; a solution of $NaHCO_3$ saturated in the cold and used in excess is the best alkali (Waitz, *Fr.* 10, 158).—(ii.) By potassium dichromate. Arsenites are converted into arsenates by the action of $K_2Cr_2O_7Aq$ in acid solutions; the residual $K_2Cr_2O_7$ is determined by a solution of $FeSO_4$; excess of HCl should be avoided (Kessler, *Fr.* [illegible]0, 205).—(iii.) By potassium permanganate. Arsenites are oxidised to arsenates by $K_2Mn_2O_8Aq$ in solutions containing H_2SO_4; an excess of $K_2Mn_2O_8$ is added, and the residual $K_2Mn_2O_8$ is determined by $FeSO_4$ solution ([illegible]aitz, *l.c.*).

References.—Besides the papers referred to in the article, the following older memoirs on arsenic and its compounds may be consulted:—Scheele, *Opus.* 2, 28; Bergmann, *Opus.* 2, 272; Buchholz, *S.* 15, 537; Laugier, *A. Ch.* 85, 26; Fischer, *S.* 6, 236; 12, 155; 39, 364; Thomson, *S.* 17, 422; 29, 430; Berzelius, *A. Ch.* [2] 5, 179; 11, 225; *S.* 34, 46; *P.* 7, 1, 137; Gehlen, *S.* 15, 501; Gay Lussac, *A. Ch.* [2] 3, 136; Pfaff, *S.* 45, 95; Buchner, *S.* 45, 419; Soubeiran, *P.* 19, 991; Mitscherlich, *A. Ch.* [2] 19.

Arsenic acid and Arsenates *v.* ARSENIC, ACIDS OF.

Arsenic, acids of.—(In connection with these compounds *v.* arts. ACIDS; ACIDS, BASICITY OF; HYDROXIDES.) Arsenious oxide, As_4O_6, dissolves in alkalis, forming salts from which other arsenites may be obtained; no hydrate of As_4O_6 is, however, known. The heat of solution of the oxide is negative; $[As^4O^6, Aq] = -15,100$. Arsenic oxide, As_2O_5, dissolves in water with formation of the hydrate H_3AsO_4, which crystallises from concentrated solutions as $2H_3AsO_4.H_2O$; these crystals heated to 100° lose water, and arsenic acid, H_3AsO_4, remains. By the action of heat on this acid, two other acids are produced, viz. at 140°-180° *pyroarsenic acid* $H_4As_2O_7$, and at 200° *metarsenic acid* $HAsO_3$; these acids dissolve in water with reproduction of H_3AsO_4. Each arsenic acid yields a series of salts; the *arsenates* (or ortho-arsenates), divisible into three classes of the forms MH_2AsO_4, M_2HAsO_4, and M_3AsO_4; the *pyroarsenates* $M_4As_2O_7$; and the *metarsenates* $MAsO_3$. The *pyro-* and *met*-arsenates have not been much investigated, they appear to exist only as solids and to yield arsenates when brought into contact with water. Thomsen's thermal examination of the behaviour of aqueous solutions of the two oxides of arsenic towards soda shows that these solutions differ much as regards reactions and hence also as regards composition. In each case the thermal behaviour of the oxide of arsenic is compared with that of the corresponding oxide of phosphorus (the formula As_2O_3 is used as being directly comparable with P_2O_3).

x	[As^2O^3Aq, xNaOHAq]	Diff.	Diff.	[P^2O^3Aq, xNaOHAq].
1	7,300			14,800
		6,500	13,700	
2	13,800			28,500
		1,200	400	
3	15,000			28,900
		600		
6	15,600			—

x	[As^2O^5Aq, xNaOHAq]	Diff.	Diff.	[P^2O^5Aq, xNaOHAq].
1	14,800			15,000
		12,300	12,600	
2	27,100			27,600
		6,900	8,400	
3	34,000			36,000
		1,300	1,400	
6	35,300			37,400

The mean thermal value of the reaction which occurs when one formula-weight of soda is added to an acid is 13,500; this value is reached when 2NaOHAq is added to As_2O_3Aq, but a little more heat is produced when a third formula-weight of soda is added. The values when baryta solution is used are $[As^2O^3Aq, BaOAq] = 14,000$; $[As^2O^3Aq, 2BaOAq] = 15,600$. It seems probable that the soda reacts with water and arsenious oxide, not with arsenious acid, to produce an arsenite $NaAsO_2.HAsO_2$, analogous to potassium arsenite, and that addition of more soda changes this either into the normal, or some other, arsenite.

---

[1] Minute attention to detailed precautions must be ob[illegible]d in testing for arsenic in poisoning cases. These [illegible] will be found in the following memoirs and [illegible]es:—Marsh, *B. J.* 17, 191; 20, 190; 22, 175; Reg[illegible] *A. Ch.* [3] 2, 159; Fresenius a. v. Babo, *A.* 49, 287; [illegible], *A.* 69, 364; Schneider, *P.* 85, 433; Fyfe, *P. M.* [illegible]; Zenger, *Fr.* 1, 391; Wöhler, a. v. Siebold, *Das* [illegible]*gericht. Verfahren bei einer Arsenik-Vergiftung* (1847); [illegible] *Ausmittelung der Gifte* [English ed. *On Poisons*]; [illegible]gendorff, *Die gerichtlich-chemische Ermittelung der Gifte* [illegible]68); Duflos, *Prüfung chem. Gifte* (1867); Taylor's [illegible]*lical Jurisprudence*; Taylor *On Poisons*.

I. ARSENIOUS ACID and ARSENITES (Pasteur, *A.* 68, 308; Filhol, *A.* 68, 308; Kühn, *Ar. Ph.* [2] 69, 267; Streng, *A.* 129, 238; Stein, *A.* 74, 218; Reynoso, *C. R.* 31, 68; Girard, *C. R.* 34, 918; 36, 973; Bloxam, *C. J.* 15, 281). No arsenious acid has been obtained in separate form; but an aqueous solution of the oxide As_4O_6 reacts with bases to form unstable salts the compositions of which may be well represented by regarding them as derived from one or other of the three hypothetical arsenious acids, $H_3AsO_3(=As(OH)_3)$, $HAsO_2(=AsO.OH)$, $H_4As_2O_5(=As_2O(OH)_4)$. The arsenites as a class are very easily decomposed; the ammonium salt gives off ammonia at ordinary temperatures and pressures, its aqueous solution yields pure As_4O_6 on evaporation; the potassium and sodium salts are decomposed in solution by carbon dioxide with separation of As_4O_6. CaO, BaO, and SrO, dissolve when boiled with water and As_4O_6, addition of lime- baryta- or strontia-water precipitates arsenites insoluble in water, but soluble in acids and in ammonia. Solutions of arsenites of metals which form sulphides soluble in water are decomposed by H_2S with precipitation of As_2S_3; if the metal of the arsenite forms a sulphide insoluble in water then H_2S precipitates this sulphide along with As_2S_3. Many arsenites are not, however, decomposed by metals even when the oxide of the metal of the arsenite is insoluble in potash. Insoluble arsenites are obtained by adding a soluble salt of the metal to a solution of K or Na arsenite. All arsenites, with the exception of those of the alkali metals, are partially or wholly insoluble in water; when formed they usually retain some arsenious oxide, so that it is difficult, and sometimes impossible, to obtain definite compounds of fixed composition. Most arsenites are decomposed by heat with formation of an arsenate and arsenic; heated with carbon, or with carbon and borax, the whole of the arsenic is usually separated in the metallic state. Heated with ammonium chloride, most arsenites yield $AsCl_3$ and chloride of the metal of the arsenite. Solutions of the alkaline arsenites exposed to the air absorb oxygen and produce arsenates (Fresenius, *J.* 1855. 382).

Arsenites. *Ammonium arsenites* $NH_4.AsO_2$ (Pasteur, Bloxam); $(NH_4)_4As_2O_5$ (Stein). By dissolving As_4O_6 in conc. aqueous NH_3; white lustrous prisms, very soluble in water.

Barium arsenites $Ba(AsO_2)_2$; white gelatinous pp. by adding $BaCl_2Aq$ to $KAsO_2Aq$ (Filhol). $BaH_4(AsO_3)_2$; by mixing $BaCl_2Aq$ with As_4O_6Aq and NH_3Aq (Bloxam). $Ba_2As_2O_5.4H_2O$; by dissolving As_4O_6 in BaOAq (Stein).

Calcium arsenites. Solutions of the various potassium arsenites mixed with $CaCl_2Aq$ yield pps. of varying composition (Filhol, Stein). A boiling solution of As_4O_6 added to CaOAq precipitates $Ca_3(AsO_3)_2$ (Kühn). $CaCl_2Aq$ mixed with As_4O_6Aq and NH_3Aq precipitates $Ca(AsO_2)_2$ (Simon, *P.* 40, 417). As_4O_6Aq with excess of CaOAq precipitates $Ca_2As_2O_5$ (Stein).

Cobalt arsenite. $Co_3H_6(AsO_3)_4.H_2O$; rose-red pp. produced by reaction of $KAsO_2Aq$ with $CoCl_2Aq$ in presence of NH_4ClAq.

Copper arsenites. $CuSO_4Aq + KAsO_2Aq$, or ammoniacal $CuSO_4Aq + As_4O_6Aq$, yields a light green pp. (Scheele's green) of $CuHAsO_3$; soluble in NH_3Aq with formation of H_3AsO_4 and Cu_2O; soluble in KOHAq with formation of K_3AsO_4, and Cu_2O, which precipitates; when heated, $CuHAsO_3$ evolves As and H_2O, and a mixture of CuO and copper arsenide remains. By digesting $CuCO_3$ with H_2O and As_4O_6 and evaporating the solution, a yellow-green salt, probably $Cu(AsO_2)_2$, is produced.

Iron arsenites. Ferrous arsenite $Fe_2As_2O_5$ is a greenish-white pp., soluble in NH_3Aq, obtained by mixing $FeSO_4Aq$ with As_4O_6Aq and a little NH_3Aq. Various ferric arsenites appear to exist. Freshly precipitated $Fe_2(OH)_6$ digested with conc. As_4O_6Aq containing not more than $\frac{1}{14}$ as much As_4O_6 as there is $Fe_2(OH)_6$, completely converts all the As_4O_6 into an insoluble salt (Bunsen); with less $Fe_2(OH)_6$ the whole of the As_4O_6 is not removed from solution, a basic salt, $FeAsO_3.Fe_2O_3$, is produced from which water removes some As_4O_6. A basic salt (rusty-red, hard, soluble in NaOHAq), $2FeAsO_3.Fe_2O_3.7H_2O$, is produced (*a*) by adding Fe_23SO_4Aq or Fe_2Cl_6Aq to $KAsO_2Aq$, (*b*) by oxidising $FeSO_4Aq$ by *aqua regia*, neutralising by NH_3Aq, adding a saturated solution of As_4O_6 in NaOHAq, and allowing to stand for twelve hours. Another salt, $2FeAsO_3.Fe_2O_3.5H_2O$, is obtained, as an ochre-yellow pp. drying to a brown mass, on mixing As_4O_6Aq or $KAsO_2Aq$ with $Fe_2(C_2H_3O_2)_6Aq$; water withdraws part of the acid from this salt; it is decomposed by heat, losing all its arsenious acid (Simon); only a part of its acid (Bunsen; *v.* also Grimaux, *Bl.* [2] 42, 211).

Lead arsenites. $Pb(AsO_2)_2$ is a white pp. (Filhol), melting to a yellow glass (Berzelius), obtained by adding $KAsO_2Aq$ to $Pb(C_2H_3O_2)_2Aq$. Other salts are known: $Pb_2As_2O(?)$ by precipitating $Pb(C_2H_3O_2)_2Aq$ by As_4O_6Aq and NH_3Aq (Filhol, Bloxam); $Pb_3(AsO_3)_2$, by precipitating $Pb(C_2H_3O_2)_2Aq$ by (*a*) boiling As_4O_6Aq (Kühn, Bloxam), or (*b*) As_4O_6 in NaOHAq (Streng, *A.* 129, 238).

Magnesium arsenites. A solution of As_4O_6 in excess of NH_3Aq mixed with $MgSO_4Aq$ with NH_4ClAq gives a pp. which is $Mg_3(AsO_3)_2$ (Stein), $MgHAsO_3.H_2O$ (Bloxam); heated to above 250° $Mg_2As_2O_5$ remains. Other salts appear to exist; but their composition is vague and uncertain (*v.* Filhol, *l.c.*).

Manganese arsenite. $Mn_3H_6(AsO_3)_4.2H_2O$ is a light rose-red pp. obtained by adding NH_4AsO_2Aq to $MnSO_4Aq$.

Mercury arsenites. Composition undecided. $Hg2NO_3Aq$ mixed with As_4O_6Aq gives a whit pp. soluble in $KAsO_2Aq$; if excess of KOH is present Hg is precipitated. An arsenite of mercury seems to be formed by mixing $HgNO_3A$ with $KAsO_2Aq$, or by digesting As_4O_6A with Hg.

Nickel arsenite. $Ni_3H_6(AsO_3)_4H_2O$ is obtained as a greenish-white pp. on adding $KAsO_2Aq$ to $NiCl_2Aq$ containing much NH_4Cl; heated in air, this salt loses H_2O, then As_4O_6, and yellow infusible $Ni_3(AsO_4)_2$ remains.

Potassium arsenites. The acid salt $KAsO_2.HAsO_2.H_2O$ is produced by adding alcohol to a solution of much As_4O_6 in KOHAq (Pasteur, Bloxam). By digesting this salt with K_2CO_3Aq the neutral salt $KAsO_2$ is produced (Pasteur, Filhol); by treating this with KOHAq and precipitating by alcohol the salt $K_4As_2O_5$ is formed (Bloxam). Two double salts, $KAsO_2.HAsO_2.AsOI$ and $K_2H_2.3As_2O_3.2KI$ are described by Emmet (*Am. S.* [2] 18, 583), and Harms (*A.* 91, 371), obtained by adding KIAq to As_4O_6Aq, or KIAq to $KAsO_2Aq$ containing so much $HC_2H_3O_2$ that no brown colour is produced with turmeric paper.

Silver arsenites. Ag_3AsO_3, a yellow pp. obtained by adding As_4O_6Aq neutralised by NH_3Aq to $AgNO_3Aq$ (Kühn, Filhol, Bloxam); soluble in HNO_3, $H.C_2H_3O_2$, NH_3Aq, and solutions of ammonium salts, also in KOHAq; solutions are not precipitated by KClAq, but dissolve freshly prepared AgCl. Heated alone or with alkalis it is decomposed;

$$4Ag_3AsO_3 = Ag_4O + 2Ag + 2Ag_3AsO_4 + As_2O_3$$

(Wöhler, *A.* 101, 363). Other silver arsenites are described by Harms (*l.c.*).

Sodium arsenites. None obtained pure; seem to be all very soluble in water (Pasteur, Filhol, Bloxam).

Strontium arsenite. $Sr(AsO_2)_2.4H_2O$. By mixing $SrCl_2Aq$ with $KAsO_2Aq$ and allowing to deposit crystals slowly (Stein).

Tin arsenites. Scarcely known; both stannous and stannic arsenites seem to exist.

II. ARSENIC ACID and ARSENATES.—(Setterberg, *B. J.* 26, 206; Baumann, *Ar. Ph.* 36, 36; Kodschonbey, *J. pr.* 49, 182; Field, *C. J.* 11, 6; Uelsmann, *Zeits. f. d. ges. Naturwiss.* 23, 347; Schiff, *A.* 112, 88; Maumené, *C. R.* 58, 250; Debray, *A. Ch.* [3] 61, 419, also *C. R.* 59, 40; Lechartier, *C. R.* 65, 172; Salkowski, *J. pr.* 104, 129). The conditions of formation of the three arsenic acids, H_3AsO_4, $HAsO_3$, and $H_4As_2O_7$ have been already described (p. 305). The following thermal data are given by Thomsen (*Th.* 2, 236) $[As, O^4, H^3] = 215,630$; $[As, O^4, H^3, Aq] = 215,230$; $[As^2O^5, 3H^2O] = 6,800$; $[AsO^4H^3, Aq] = -400$; $[As^2, O^7, H^4] = 360,830$; $[As^2O^5, Aq] = 6,000$; $[As^2O^3, O^2] = 64,710$; $[As^2O^3Aq, O^2] = 78,260$. The following heats of neutralisation are also given by Thomsen (*Th.* 1, 196):

$n\,[NaOHAq, nH^3AsO^4Aq]$;

n	
$\frac{1}{6}$	6,233
$\frac{1}{3}$	11,972
$\frac{1}{2}$	13,790
1	14,994
2	14,724

$n\,[nNaOHAq, H^3AsO^4Aq]$.

n		Diff.
$\frac{1}{3}$	7,362	
1	14,994	
		12,586
2	27,580	
		7,336
3	35,916	
		1,484
6	37,400	

The acid H_3AsO_4 is therefore tribasic; but as the reaction of the third formula-weight of soda is accompanied by the production of not much more than half the quantity of heat which accompanies the reaction of the first or second formula-weight, it is probable that this acid belongs to the same class of tribasic acids as phosphoric acid, which class is represented by Thomsen by the typical formula $HR(OH)_2H$ (*v.* ACIDS, BASICITY OF). The relative affinity of arsenic acid (*v.* AFFINITY) is 21 (that of HNO_3 = 100) which is a little less than the value for phosphoric acid.

The acid H_3AsO_4 forms translucent crystals; the acid $H_4As_2O_7$ clear lustrous crystals; and the meta-acid $HAsO_3$ a white somewhat iridescent solid; the ortho-acid dissolves in water with disappearance of heat (*v. supra*), the other acids dissolve with production of heat and formation of the ortho-acid; $[H^4As^2O^7, Aq] = 1,300$ (Thomsen, *B.* 7, 1003).

The following facts refer to the ortho-acid H_3AsO_4.

Formation.—By action of HNO_3Aq on As or As_4O_6.

Preparation.—Arsenious oxide is suspended in water and chlorine is passed in; the solution is evaporated to dryness in a platinum dish, the temperature not being allowed to rise much above 100°; the residue is dissolved in water and evaporated slowly at 100°; after a time small needle-shaped crystals of H_3AsO_4 separate out (E. Kopp, *J. pr.* 69, 270).

Properties.—Action of heat already described (*v.* p. 305). Aqueous solution tastes sour and metallic; it burns the skin. The most concentrated solution has S.G. 2·5; the following table gives some data regarding S.G. of aqueous solutions (Schiff, *A.* 113, 183).

S.G. at 15°		Pctge. of H_3AsO_4	
	1·7346		67·4
„	1·3973	„	45·0
„	1·2350	„	30·0
„	1·1606	„	22·5
„	1·1052	„	15·0
„	1·0495	„	7·5

Reactions.—1. Heated with *carbon*, many *metals*, or *potassium cyanide*, it yields arsenic.—2. Heated with *conc. hydrochloric acid* $AsCl_3$ and Cl are produced; if the S.G. of the aqueous HCl used is less than 1·04 no $AsCl_3$ is produced (Fresenius and Souchay, *Fr.* 1, 448); with acid of S.G. 1·1 traces of $AsCl_3$ are formed (Mayrhofer, *A.* 158, 326).—3. *Sulphurous acid* produces arsenious oxide and sulphuric acid (Wöhler, *A.* 30, 224).—4. *Zinc* and *iron* dissolve in aqueous H_3AsO_4 with evolution of H and AsH_3 and production of gelatinous solids (? arsenates of Zn or Fe); in presence of H_2SO_4, these metals precipitate As, and evolve H and AsH_3.—5. *Sulphydric acid* (H_2S) reduces H_3AsO_4 in solution to As_2O_3, with precipitation of S, and then throws down As_2S_3; this reaction takes place slowly at 10°–15°, but more rapidly at 60°–70°. 6. *Sodium thiosulphate solution*, in presence of HCl, produces a pp. of As_2S_5 (*q. v.*).—7. *Tungstates of potassium, ammonium, and silver* when evaporated with KH_2AsO_4 solution yield complex compounds, viz., $6WO_3.As_2O_5.3K_2O.3H_2O$; $6WO_3.As_2O_5.4(NH_4)_2O.5H_2O$; and $16WO_3.As_2O_5.6Ag_2O.11H_2O$ (Gibbs, *P. Am. A.* 15, 1; 16, 109; *v.* also Debray, *C. R.* 78, 1408; and Seyberth, *B.* 7; also Sonnenschein, *J. pr.* 53, 339, 391). Derivatives of arsenic acid in which OH is replaced by Cl, or Br, or I, are not known.

Arsenates. Arsenates are isomorphous with corresponding phosphates. The arsenates of the alkali metals, and the acid arsenates of the alkaline earth metals, are soluble in water; they lose all their arsenic as chloride by strongly heating with sal-ammoniac (Rose, *P.* 116, 453). The neutral and basic arsenates are easily soluble in mineral acids, including arsenic acid. Debray (*l.c.*) describes a series of amorphous arsenates, $MH_2AsO_4.H_2O$, obtained by precipitating alkaline arsenates by salts of the metals M; these arsenates become crystalline, according to Debray, by long-continued digestion with the liquids in which they are produced. By fusing chlorides and fluorides with arsenates, Lechartier (*l.c.*) obtained a series of crystalline salts analogous in composition to *Wagnerite* and *Apatite*; thus:

Corresponding to *Wagnerite* $[(PO_4.F.Mg_2)]$.
$AsO_4.Cl.Ca_2$
$AsO_4.Cl(F).Mg_2$
$AsO_4.Cl.Mg_2$
$AsO_4.Cl.Mn_2$

Corresponding to *Apatite* $[(PO_4)_3.Cl(F).Ca_5]$.
$(AsO_4)_3.Cl.Ca_5$
$(AsO_4)_3.Cl(F).Ca_5$
$(AsO_4)_3.Cl.Pb_5$
$(AsO_4)_3.Cl.Sr_5$
$(AsO_4)_3.Cl.Ba_5$.

Debray also obtained the following crystallised insoluble arsenates by digesting arsenic acid solution with carbonates of the various metals: $2AsO_4CaH.H_2O$; AsO_4CuH; $2AsO_4CuH.3H_2O$; $(AsO_4)_2Cu_3.4H_2O$; and $AsO_4Cu.(CuOH)$. Arsenates are usually prepared by adding Na_2HAsO_4Aq to solutions of salts of the various metals, using the calculated masses of the reacting bodies.

Aluminium arsenate. White pp. by adding a soluble arsenate to a solution of an Al salt.

Ammonium arsenates. $(NH_4)_2.H_2AsO_4$; by adding NH_3Aq to conc. H_3AsO_4 until the pp. which forms is dissolved (Salkowski). $(NH_4)_3AsO_4.3H_2O$; by adding considerable excess of NH_3Aq to H_3AsO_4Aq. $NH_4H_2AsO_4$; by adding one formula-weight H_3AsO_4 to one formula-weight $(NH_4)_2HAsO_4$.

Barium arsenates. $BaHAsO_4$; crystalline, obtained by adding Na_2HAsO_4Aq to $BaCl_2Aq$. Ba_32AsO_4; crystalline, obtained by adding Na_3AsO_4Aq to $BaCl_2Aq$; acted on by water it forms the salt $BaHAsO_4$ (Field). The salt $BaH_4(AsO_4)_2$ is obtained by dissolving $BaHAsO_4$ in warm H_3AsO_4Aq and allowing to crystallise (Setterberg). Two barium-ammonium arsenates $2Ba.NH_4.AsO_4.H_2O$, and $BaH_2(NH_4)_2(AsO_4)_2$ are described (Baumann, Mitscherlich).

Bismuth arsenate. $2BiAsO_4.H_2O$; yellowish white pp. insoluble in water and HNO_3Aq, soluble in HClAq; insoluble in a conc. solution of $Bi3NO_3$ containing a little free acid (Schneider, *J. pr.* [2] 20, 418).

Cadmium arsenates. White crystalline pps. obtained by precipitating solution of Cd salts by Na_2HAsO_4Aq; two are known, $Cd_3(AsO_4)_2.3H_2O$ and $Cd_5H_2(AsO_4)_4.4H_2O$ (Salkowski).

Calcium arsenates. $Ca.H.AsO_4$; prepared like $BaHAsO_4$; occurs native as *Pharmacolite*. By treatment with NH_3Aq this salt yields $Ca_3(AsO)_4$ (Kotschonbey). Two calcium-ammonium arsenates are described, $CaH_2(NH_4)_2(AsO_4)_2$ and $CaNH_4.AsO_4.6$ or $7H_2O$ (Baumann, Kotschonbey; also Bloxam, *C. N.* 54, 163). The salt $Ca_2As_2O_7$ is obtained by strongly heating $Ca.NH_4.AsO_4.7H_2O$ (Bloxam).

Cerium arsenate. $Ce.H.AsO_4$; insoluble in water, soluble in excess of H_3AsO_4Aq.

Cobalt arsenates. $CoHAsO_4$ is unknown; $CoH_4(AsO_4)_2$ obtained by evaporating *in vacuo* solution of $CoO.H_2O$ in excess of H_3AsO_4Aq. Cobaltic arsenate, $Co_3 2AsO_4 8H_2O$ (Karsten, *P.* 60, 266) is a reddish powder obtained by precipitating the solution of a Co salt by Na_3AsO_4Aq; occurs native as *Cobalt-bloom*. An impure basic arsenate of cobalt is known in commerce as *Chaux métallique*.

Copper arsenates. $Cu_5H_2(AsO_4)_4.2H_2O$; obtained as a blue pp. by adding $(NH_4)_2HAsO_4Aq$ to $CuSO_4Aq$ and drying at 130° (Salkowski). $Cu_3(AsO_4)_2$ is a green powder obtained by precipitating $CuSO_4Aq$ with Na_2HAsO_4Aq; this salt dissolves in NH_3Aq, and on long standing, clear blue crystals having the composition $[(NH_3)_2Cu]_3(AsO_4)_2$ separate out (Damour, *B. J.* 26, 247; and 27, 181). Various basic arsenates of copper occur native as minerals (*v.* Coloriano, *Bl.* [2] 45, 707).

Chromium arsenates. Chromic arsenate is a green pp. obtained by mixing solutions of a chromic salt and K_3AsO_4; composition uncertain. By mixing solutions of K_2CrO_4 and H_3AsO_4 Schweizer (*J. pr.* 39, 267) obtained a gelatinous pp. having the composition (dried at 100°) $(CrO)_3AsO_4.K_2H(AsO_4)_2.4H_2O$.

Didymium arsenate. $Di_3(AsO_4)_2.DiH(AsO_4)_2.H_2O$; by boiling H_3AsO_4Aq with Di_2O_3 (Marignac, *A. Ch.* 88, 185).

Iridium arsenate is a brown pp.

Iron arsenates. The ferrous salt is obtained by double decomposition; it oxidises easily; after drying, its composition is $Fe_2OAsO_4.5\frac{1}{3}H_2O$ (Wittstein, *Viertel-jahrsschr. pr. Pharm.* 15, 185). The ferric salt $(?FeH_3(AsO_4)_2)$ is obtained by mixing Fe_2Cl_6Aq with Na_2HAsO_4Aq; it is a white powder which loses water on heating and becomes reddish, soluble in H_3AsO_4Aq, but this solution soon decomposes, unless very concentrated, depositing $Fe_2(OH)_6$ (Lunge, *Fr.* 6, 185). Various other ferric arsenates of uncertain composition have been described by Berzelius (*v.* also Grimaux, *Bl.* [2] 42, 211).

Lead arsenates. The salt $PbHAsO_4$ is obtained by double decomposition (Salkowski); when treated with NH_3Aq it yields $Pb_3(AsO_4)_2$.

Lithium arsenates. $2Li_3AsO_4.H_2O$ is a white powdery pp. obtained by dissolving Li_2CO_3 in H_3AsO_4Aq and adding NH_3Aq; when this salt is dissolved in H_3AsO_4Aq, trimetric prisms of $2LiH_2AsO_4.3H_2O$ crystallise out (Rammelsberg, *P.* 128, 311).

Magnesium arsenates. $2MgHAsO_4.13H_2O$; white pp. by mixing 5 parts Na_2HAsO_4 in solution with a dilute solution of 3 parts $MgSO_4$ (Graham, *A.* 29, 24). $Mg_3(AsO_4)_2$ is obtained by boiling the preceding salt for some time with conc. Na_2HAsO_4Aq. A magnesium-ammonium arsenate $MgNH_4AsO_4.6H_2O$ is obtained by adding H_3AsO_4Aq with excess of NH_3Aq to $MgSO_4Aq$ containing NH_4Cl; it is slightly soluble in NH_4ClAq, strongly heated it loses NH_3 and $Mg_2As_2O_7$ remains [H. Rose; Field; Wittstein; Puller; Fresenius (*Fr.* 3, 206); Levol (*A. Ch.* [3] 17, 50)]. A magnesium-potassium arsenate $MgKAsO_4$, and a corresponding sodium salt, are obtained by fusing $MgHAsO_4$ with K_2CO_3 and KOH (or Na_2CO_3 and NaOH).

Manganese arsenates. $MnHAsO_4$ is produced by saturating H_3AsO_4Aq with $MnCO_3$; using excess of H_3AsO_4Aq the salt $MnH_4(AsO_4)_2$ is formed (Schiefer). The manganese-ammonium salt $MnNH_4AsO_4.6H_2O$ is obtained like the corresponding Mg salt as a gummy pp. which becomes crystalline. Some basic Mn arsenates are described by Coloriano (*Bl.* [2] 45, 709).

Mercury arsenates. The mercurous salt Hg_2HAsO_4 is a yellowish white pp., which becomes orange red, produced by adding H_3AsO_4Aq to $HgNO_3Aq$; it is insoluble in water and $H.C_2H_3O_2Aq$, soluble in HNO_3Aq. When heated, this salt loses H_2O and Hg, and a mercuric salt (probably $Hg_2As_2O_7$) remains. By adding an excess of H_3AsO_4Aq to the mercurous salt, and evaporating, the meta-salt $Hg_2(AsO_3)_2$ is obtained as a white powder, somewhat soluble in HNO_3Aq, decomposed by HClAq with formation of HgCl, decomposed by KOHAq with withdrawal of half its arsenic as H_3AsO_4 (Simon, *P.* 41, 424).

Molybdenum arsenate is a grey pp. (for combinations of As_2O_5 with MoO_3 and K_2O *v.* Arsenic Acid, *Reactions*, No. 7).

Nickel arsenates. Analogous to cobalt arsenates (*q. v.*). The salt $Ni_3(AsO_4)_2.8H_2O$ occurs native as *Nickel-bloom.*

Palladium arsenate is a clear yellow pp. obtained by heating Na_2HAsO_4Aq with $Pd.2NO_3Aq$.

Platinum arsenate is a light-brown pp. obtained like the Pd salt.

Potassium arsenates. The salts K_3AsO_4 and K_2HAsO_4 are obtained by adding K_2CO_3 or KOH to H_3AsO_4Aq; the former crystallises from very conc. solutions (Graham, *P.* 32, 47). By heating together equal parts of KNO_3 and As_4O_6, dissolving in water and evaporating, or by adding KOHAq to H_3AsO_4Aq until neutral to litmus and crystallising, the salt KH_2AsO_4 is obtained. The crystals of this salt are fairly soluble in water (S. 6° = 19), insoluble in alcohol. Heated above 288° the salt melts to a glassy mass.

Silver arsenates. Ag_3AsO_4 is a dark red-brown pp. produced by mixing H_3AsO_4Aq, or solution of an alkaline arsenate, with $AgNO_3Aq$; it melts to a brownish-red glass, it is decomposed by HClAq to AgCl and H_3AsO_4Aq, it is soluble in $HC_2H_3O_2Aq$, NH_3Aq, and solutions of many NH_4 salts. By digesting this salt for some time at a gentle heat with H_3AsO_4Aq a white salt, $2AgAsO_3.As_2O_5$, is obtained.

Sodium arsenates. $Na_2HAsO_4.12H_2O$, S.G. 1·67 (Schiff), is obtained in large crystals, isomorphous with common sodium phosphate, by adding a slight excess of Na_2CO_3Aq to H_3AsO_4Aq, and evaporating at a temperature not higher than 18° (Fresenius, *J. pr.* 56, 30). The crystals which form at 20° and upwards contain $7H_2O$, S.G. 1·87 (Schiff); the crystals with $12H_2O$ effloresce quickly, those with $7H_2O$ do not. The salt melts when heated forming a clear transparent liquid. At 0° a salt crystallises with $13\frac{1}{2}H_2O$ (Setterberg). The salt $NaH_2AsO_4.H_2O$ is formed in large crystals by adding Na_2CO_3Aq to H_3AsO_4Aq until the solution is no longer ppd. by $BaCl_2Aq$; isomorphous with the corresponding phosphate; S.G. 2·535 (Schiff). A solution of S.G. about 1·7 gives crystals of $NaH_2AsO_4.2H_2O$ (Joly a. Dufet, *C. R.* 102, 1391). A conc. solution of H_3AsO_4 decomposes NaClAq and $NaNO_3$ on heating. Two double salts, viz. $NaKHAsO_4.7H_2O$ (Schiff), or $9H_2O$ (Kotschonbey), and $NaNH_4HAsO_4.4H_2O$, are described (Uelsmann). The former is obtained by neutralising NaH_2AsO_4Aq by K_2CO_3Aq, the latter by mixing solutions of Na_2HAsO_4 and $(NH_4)_2HAsO_4$. The compound $Na_3AsO_4.NaF.12H_2O$ crystallises in monometric octahedra; it resembles common alum in appearance; S.G. 2·849; S. (25°) = 10·5; S. (75°) = 50. This salt is obtained by fusing together, with special precautions, 1 part As_4O_6, 4 parts Na_2CO_3, 3 parts $NaNO_3$, and 1 part CaF_2 (Briegleb, *A.* 97, 95). Two compounds of sodium arsenates with sulphates seem to exist $Na_8As_6O_{19}.2Na_2SO_4$ (Mitscherlich), and $Na_4As_2O_7.Na_2SO_4$ (Setterberg).

Strontium arsenates. By adding Na_2HAsO_4Aq to $SrCl_2Aq$ a pp. of $SrNaAsO_4.H_2O$ is obtained; the filtrate from this when evaporated gives a white pp. of $SrHAsO_4$ (Salkowski).

Tin arsenates. $2SnHAsO_4.H_2O$; a white pp. produced by adding excess of K_2HAsO_4Aq to $SnCl_2Aq$; by the reverse process the salt $Sn(SnCl)AsO_4.H_2O$ is said to be formed (Lennsen, *A.* 114, 113).

Zinc arsenate $Zn_3(AsO_4)_2.3H_2O$ is a gelatinous substance (Köttig, *J. pr.* 48, 182 and 256); the salts $ZnHAsO_4$, $ZnH_4(AsO_4)_2$, and $Zn_3(AsO_4)_2.NH_3$, are also known (*v.* also Friedel, *Bl.* [2] 5, 433).

The compositions of the remaining arsenates, which have been very slightly investigated, are expressed by the following formulæ: –

Thallium, $Tl.AsO_4.2H_2O$. *Thorium*, $Th.HAsO_4$. *Uranium*, $(UO)_2HAsO_4.4H_2O$; the salts $(UO)_2NaAsO_4$ and $(UO)_4Cu(AsO_4)_2.8H_2O$ are also known (Werther, *A.* 68, 312). *Vanadium*, $VH_2(AsO_4)_2$. *Yttrium*, $YHAsO_4$. Arsenates of titanium and zirconium are said to have been obtained.

Arsenic, alloys of, ***v.*** Arsenic, *Combinations of*, No. 9.

Arsenic, ammonio-chloride of, ***v.*** Arsenic chloride, *Combinations of*, No. 2.

Arsenic, bromide of. $AsBr_3$ (*Arsenious bromide, Tribromide of arsenic*). Mol. w. 314·25. [20°–25°]. (220°). S.G. 3·66 (Boedeker, *J.* 1860. 17). V.D. 157·5. H.F. 59,100 solid As, gaseous Br (Guntz, *C. R.* 101, 161). S.V.S. 85·8.
